Intel®Fortran Compiler 19.1 Developer Guide and Reference

The following are some important features of the compiler:

Compiler Setup

Compiler Setup explains how to invoke the compiler on the command line or from within an IDE.

OpenMP* Support

The compiler supports many OpenMP* features, including most of OpenMP* Version TR4: Version 5.0.

Compiler Options

Compiler Options provides information about options you can use to affect optimization, code generation, and more.

Language Reference

The Language Reference provides information on language syntax and semantics, on adherence to various Fortran standards, and on extensions to those standards.

For information about the Fortran standards, visit the Fortran standards technical committee website at http://j3-fortran.org/.

Fortran Language Extensions

Fortran Language Extensions provides information about how to use additional implementation features, such as creating a Component Object Model server and generating listing and map files, among others.

Mixed Language Programming

Mixed Language Programming provides information about Fortran and C interoperable procedures and data types, as well as various specifics of mixed-language programming.

List of Run-Time Error Messages

List of Run-Time Error Messages describes the errors processed by the Intel® Fortran run-time library (RTL).

Context Sensitive/F1 Help

To use the Context Sensitive/F1 Help feature, visit the Download Documentation: Intel® Compiler (Current and Previous) page and follow the instructions provided there.

Part I

Introducing the Intel®Fortran Compiler

Using the Intel®Fortran Compiler , you can compile and generate applications that can run on Intel® 64 architecture. You can also create programs for the IA-32 architecture on Windows* and Linux*.

Intel® 64 architecture applications can run on the following:

- Windows* operating systems for Intel® 64 architecture-based systems.
- Linux* operating systems for Intel® 64 architecture-based systems.
- macOS* operating systems for Intel® 64 architecture-based systems.

IA-32 architecture applications can run on the following:

- Supported Windows* operating systems
- Supported Linux* operating systems

NOTE
Starting with the 19.0 release of the Intel®Fortran Compiler, macOS* 32-bit applications are no longer supported. If you want to compile 32-bit applications, you must use an earlier version of the compiler and you must use Xcode* 9.4 or earlier.

Unless specified otherwise, assume the information in this document applies to all supported architectures and all operating systems.

You can use the compiler in the command-line or in a supported Integrated Development Environment (IDE):

- Microsoft Visual Studio* (Windows* only)
- Eclipse*/CDT (Linux* only)
- Xcode* (macOS* only)

See the Release Notes for complete information on supported architectures, operating systems, and IDEs for this release.

Optimization Notice
Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice. Notice revision #20110804

Feature Requirements

To use these tools and features, you need licensed versions of the tools and you must have an appropriately supported version of the product edition. For more information, check the product release notes.

NOTE Some features may require additional product installation.

The following table shows components (tools) and where to find additional information on them.

Component	More Information
Intel® Inspector Intel® Trace Analyzer and Collector	More information on tools and features can be found on the Intel IDZ: http://software.intel.com/

The following table lists dependent features and their corresponding required products. For certain compiler options, the compilation may fail if the option is specified but the required product is not installed. In this case, remove the option from the command line and recompile. For more information about requirements for a particular product, see http://www.intel.com/software/products/.

Feature Requirements

Feature	Requirement
Thread Checking	Intel® Inspector
Trace Analyzing and Collecting	Intel® Trace Analyzer and Collector Compiler options related to this feature may require a set-up script. For further information, see the product documentation.
Coarray programs built to run using distributed memory	Intel® Parallel Studio XE Cluster Edition for Windows* or Linux*

Other Tools

Feature	Requirement
Privatization of static data for the MultiProcessor Computing (MPC) unified parallel runtime	MPC framework elements The MPC unified parallel runtime must be installed. For more information, see http://mpc.hpcframework.com/

Refer to the Release Notes for detailed information about system requirements, late changes to the products, supported architectures, operating systems, and Integrated Development Environments (IDEs).

Getting Help and Support

Windows*

Documentation is available from within the version of Microsoft Visual Studio*. You must install the documentation on your local system. To use the feature, visit the Download Documentation: Intel® Compiler (Current and Previous) page and follow the instructions provided there. From the **Help** menu, choose **Intel Compilers and Libraries** to view the installed user and reference documentation.

Linux* and macOS*

On Linux and macOS*, the documentation has limited integration in the Eclipse*/CDT and Xcode*. In both cases, the integrated documentation only provides details about where to find the product documentation on your local system.

Intel Software Documentation

You can find product documentation for many released products at: http://software.intel.com/en-us/intel-software-technical-documentation/

Product Website and Support

To find product information, register your product, or contact Intel, visit: https://software.intel.com/en-us/support/

At this site, you will find comprehensive product information, including:

- Links to Get Started, Documentation, Individual Support, and Registration
- Links to information such as white papers, articles, and user forums
- Links to product information
- Links to news and events

Online Service Center

Each purchase of an Intel® Software Development Product includes a year of support services, which includes priority customer support at our Online Service Center. For more information about the Online Service Center visit: https://software.intel.com/en-us/support/online-service-center

> **NOTE** To access support, you must register your product at the Intel® Registration Center: https://registrationcenter.intel.com

Release Notes

For detailed information on system requirements, late changes to the products, supported architectures, operating systems, and Integrated Development Environments (IDE) see the Release Notes for the product.

Forums

You can find helpful information in the Intel Software user forums. You can also submit questions to the forums. To see the list of the available forums, go to https://software.intel.com/en-us/forum/

Related Information

Reference and Tutorial Information

The following commercially published documents provide reference or tutorial information about Fortran:

- *Introduction to Programming with Fortran with coverage of Fortran 90, 95, 2003, 2008 and 77*, by I.D. Chivers and J. Sleightholme; published by Springer, ISBN 9780857292322
- *The Fortran 2003 Handbook: The Complete Syntax, Features and Procedures*, by Adams, J.C., Brainerd, W.S., Hendrickson, R.A., Maine, R.E., Martin, J.T., Smith, B.T., published by Springer Verlag, ISBN 9781846283789
- *Fortran 95/2003 For Scientists and Engineers*, by Chapman S.J., published by McGraw- Hill, ISBN 0073191574
- *Modern Fortran Explained: Incorporating Fortran 2018*, by Metcalf M., Reid J. and Cohen M., 2018, published by Oxford University Press, ISBN-13: 978-0198811886

Intel does not endorse these books or recommend them over other books on the same subjects.

Additional Product Information

For additional technical product information including white papers, forums, and documentation, visit https://software.intel.com/en-us/intel-sdp-home/

Additional Language Information

- For information about the OpenMP* standards, visit the OpenMP website: http://www.openmp.org/
- For information about the Fortran standards, visit the Fortran standards technical committee website: http://j3-fortran.org/

Notational Conventions

Information in this documentation applies to all supported operating systems and architectures unless otherwise specified. This documentation uses the following conventions:

Notational Conventions

THIS TYPE	Indicates statements, data types, directives, and other language keywords. Examples of statement keywords are WRITE, INTEGER, DO, and OPEN.
this type	Indicates command-line or option arguments, new terms, or emphasized text. Most new terms are defined in the Glossary.
`This type`	Indicates a code example.
`This type`	Indicates what you type as input.
This type	Indicates menu names, menu items, button names, dialog window names, and other user-interface items.
File > Open	Menu names and menu items joined by a greater than (>) sign to indicate a sequence of actions. For example, **Click File > Open** indicates that in the **File** menu, you would click **Open** to perform this action.
{value | value}	Indicates a choice of items or values. You can usually only choose one of the values in the braces.
[*item*]	Indicates items that are optional. Brackets are also used in code examples to show arrays.
item [, *item*]...	Indicates that the item preceding the ellipsis (...) can be repeated. In some code examples, a horizontal ellipsis means that not all of the statements are shown.
Intel® Fortran	This term refers to the name of the common compiler language supported by the Intel® Fortran Compiler.
Windows* or Windows* operating system	These terms refer to all supported Microsoft Windows* operating systems.

Linux* or Linux* operating system	These terms refer to all supported Linux* operating systems.
macOS* or macOS* operating system	These terms refer to all supported macOS* operating systems.
Microsoft Visual Studio*	An asterisk at the end of a word or name indicates it is a third-party product trademark.
compiler option	This term refers to Linux*, macOS*, or Windows* options, which are used by the compiler to compile applications. The following conventions are used as shortcuts when referencing compiler option names in text: • Many options have names that are the same on Linux*, macOS*, and Windows*, except that the Windows* form starts with an initial / and the Linux* and macOS*form starts with an initial -. Within text, such option names are shown without the initial character. For example, `check`. • Many options have names that are the same on Linux*, macOS*, and Windows*, except that the Windows* form starts with an initial Q. Within text, such option names are shown as `[Q]option-name`. For example, if you see a reference to `[Q]ipo`, the Linux* and macOS* form of the option is `-ipo` and the Windows* form of the option is `/Qipo`. • Several compiler options have similar names except that the Linux* and macOS* forms start with an initial q and the Windows* form starts with an initial Q. Within text, such option names are shown as `[q or Q]option-name`. For example, if you see a reference to `[q or Q]opt-report`, the Linux* and macOS* form of the option is `-qopt-report` and the Windows* form of the option is `/Qopt-report`. Other dissimilar compiler option names are shown in full.

Conventions Used in Compiler Options

`/option` or `-option`	A slash before an option name indicates the option is available on Windows*. A dash before an option name indicates the option is available on Linux* and macOS* systems. For example: • Windows* option: `/help` • Linux* and macOS*option: `-help`

NOTE If an option is available on all supported operating systems, no slash or dash appears in the general description of the option. The slash and dash only appear where the option syntax is described.

`/option:argument` or `-option=argument`	Indicates that an option requires an argument (parameter). For example, you must specify an argument for the following options: • Windows* option: `/tune:`*processor* • Linux* and macOS* option: `-mtune=`*processor*
`/option:`*keyword* or `-option=`*keyword*	Indicates that an option requires one of the *keyword* values.
`/option`[`:`*keyword*] or `-option`[`=`*keyword*]	Indicates that the option can be used alone or with an optional keyword.
`option`[*n*] or `option`[`:`*n*] or `option`[`=`*n*]	Indicates that the option can be used alone or with an optional value. For example, in `/Qunroll`[`:`*n*] and `-unroll`[`=`*n*], the *n* can be omitted or a valid value can be specified for *n*.
`option`[`-`]	Indicates that a trailing hyphen disables the option. For example, `/Qglobal_hoist-` disables the Windows* option `/Qglobal_hoist`.
`[no]option` or `[no-]option`	Indicates that `no` or `no-` preceding an option disables the option. For example, in the Windows* option `/[no]traceback`, `/traceback` enables the option, while `/notraceback` disables it. In the Linux* and macOS* option `-[no-]global_hoist`, `-global_hoist` enables the option, while `-no-global_hoist` disables it. In some options, the `no` appears later in the option name. For example, `-fno-common` disables the `-fcommon` option.

Conventions Used in Language Reference

This color	Indicates Intel extensions (non-standard features) that may or may not be implemented by other compilers. Features defined by the Fortran Standards or the OpenMP* Standards are shown in black.
Fortran	This term refers to language information that is common to previously supported Fortran standards, Fortran 2008, and the Intel® Fortran Compiler.

Standard Fortran	This term refers to language information that is common to ANSI/ISO Fortran 95, ANSI/ISO Fortran 90, and Intel® Fortran.
Fortran 95	This term refers to language features specific to ANSI/ISO Fortran 95.
Fortran 2003	This term refers to language features specific to ANSI/ISO Fortran 2003.
Fortran 2008	This term refers to language features specific to ISO/IEC 1539-1:2010 (Fortran 2008).
Fortran 2018	This term refers to language features specific to the Draft International Fortran standard expected to be published late 2018 or early 2019.
integer	This term refers to the INTEGER(KIND=1), INTEGER(KIND=2), INTEGER (INTEGER(KIND=4)), and INTEGER(KIND=8) data types as a group.
INTEGER	This term refers to the default data type of objects declared to be INTEGER. INTEGER is equivalent to INTEGER(KIND=4), unless a compiler option specifies otherwise.
real	This term refers to the REAL (REAL(KIND=4)), DOUBLE PRECISION (REAL(KIND=8)), and REAL(KIND=16) data types as a group.
REAL	This term refers to the default data type of objects declared to be REAL. REAL is equivalent to REAL(KIND=4), unless a compiler option specifies otherwise.
complex	This term refers to the COMPLEX (COMPLEX(KIND=4)), DOUBLE COMPLEX (COMPLEX(KIND=8)), and COMPLEX(KIND=16) data types as a group.
COMPLEX	This term refers to the default data type of objects declared to be COMPLEX. COMPLEX is equivalent to COMPLEX(KIND=4), unless a compiler option specifies otherwise.
logical	This term refers to the LOGICAL(KIND=1), LOGICAL(KIND=2), LOGICAL (LOGICAL(KIND=4)), and LOGICAL(KIND=8) data types as a group.
LOGICAL	This term refers to the default data type of objects declared to be LOGICAL. LOGICAL is equivalent to LOGICAL(KIND=4), unless a compiler option specifies otherwise.
< Tab>	This symbol indicates a nonprinting tab character.
^	This symbol indicates a nonprinting blank character.

Platform Labels

A platform is a combination of an operating system (OS) and a central processing unit (CPU), which provides a distinct environment for product use (in this case, a computer language). An example of a platform is Microsoft Windows* on processors using Intel® 64 architecture.

In this documentation, the information applies to all supported platforms unless it is otherwise labeled for a specific platform (or platforms).

These labels may be used to identify specific platforms:

L*X	Applies to a Linux* operating system.
M*X	Applies to a macOS* operating system.
W*S	Applies to a Microsoft Windows* operating system.

Part II

Compiler Setup

You can use the Intel®Fortran Compiler from the command line, or from the IDEs listed below.

These IDEs are described in further detail in their corresponding sections.

Using the Command Line

Specifying the Location of Compiler Components with compilervars

Before you invoke the compiler, you may need to set certain environment variables that define the location of compiler-related components.

The Intel® Fortran Compiler includes `compilervars` scripts to set environment variables:

- On Linux* and macOS*, the file is a shell script called `compilervars.sh` or `compilervars.csh`.
- On Windows*, the file is a batch file called `compilervars.bat`.

The following information is operating system dependent.

> **NOTE** IA-32 architecture is no longer supported on macOS*.

Linux and macOS*:

Set the environment variables before using the compiler by sourcing the shell script `compilervars.sh` or `compilervars.csh`. Depending on the shell, you can use the `source` command or a `.` (dot) to source the shell script, according to the following rules:

- **`.csh` script**: Use the `source` command.
- **`.sh` script**:
  - Bash: Use either the `source` command or `.` (dot space).
  - Dash or other POSIX-compliant shell: Use `.` (dot space).

```
//# Bash shell:
source /<install-dir>/bin/compilervars.sh <arg>
. /<install-dir>/bin/compilervars.sh <arg>

//# examples: (assuming <install-dir> is /installed/compiler/)
prompt> source /installed/compiler/bin/compilervars.sh intel64
prompt> . /installed/compiler/bin/compilervars.sh intel64

// OR//# C shell:
source /<install-dir>/bin/compilervars.csh <arg>

//# example: (assuming <install-dir> is /installed/compiler/)
```

```
prompt> source /installed/compiler/bin/compilervars.csh intel64

// OR//# Dash or other POSIX-compliant shell:
. /<install-dir>/bin/compilervars.sh <arg>

//# example: (assuming <install-dir> is /installed/compiler/)
prompt> . /installed/compiler/bin/compilervars.sh intel64
```

The environment script file requires a target architecture argument `<arg>`:

- `ia32`: Compiler and libraries for IA-32 architecture-based targets only.
- `intel64`: Compiler and libraries for Intel® 64 architecture-based targets only.

If you want the script to run automatically, add the same command to the end of your startup file.

For example, a `.bash_profile` entry for `compilervars.sh` for IA-32 architecture targets only:

```
# set environment vars for Intel(R)  Fortran Compiler
source <install-dir>/bin/compilervars.sh ia32
```

> **NOTE** Symbolic links are created in the `/opt/intel` directory at install. The environment variables use symbolic links. When two versions of the Intel® Fortran Compiler are installed, the newest installed version is symbolically linked.

If the proper environment variables are not set, an error similar to the following appears when attempting to execute a compiled program:

```
./a.out: error while loading shared libraries:
libimf.so: cannot open shared object file: No such file or directory
```

Windows:

Under normal circumstances, you do not need to run the `compilervars.bat` batch file. The installed shortcut **Compiler 19.1 for IA-32 Visual Studio <Year> environment** sets these variables automatically.

For information on using the command line see Using the Command Line on Windows.

> **NOTE** You need to run the batch file if a command line is opened without using one of the provided menu items in the **Start** menu, or if you want to use the compiler from a script of your own.

The batch file inserts the directories used by the Intel® Fortran Compiler at the beginning of the existing paths. Because these directories appear first, they are searched before the directories in the path lists that are provided by Windows. This is especially important if the existing path includes directories with files that have the same names as those needed by the Intel® Fortran Compiler .

If needed, you can run `compilervars.bat` each time you begin a session on Windows systems by specifying it as the initialization file with the PIF Editor.

The batch file takes two arguments:

```
<install-dir>\bin\compilervars.bat <arg1> [<arg2>]
```

Where *<arg1>* is one of the following:

- `intel64`: Compiler and libraries for Intel® 64 architecture only (host and target).
- `ia32`: Compiler and libraries for IA-32 architecture only (host and target).

The *<arg2>* is optional. If specified, it is one of the following:

- `vs2019`: Microsoft Visual Studio* 2019
- `vs2017`: Microsoft Visual Studio 2017

> **NOTE** If <*arg2*> is not specified, the script uses the highest installed version of Microsoft Visual Studio detected during the installation procedure.

Invoking the Intel® Compiler

Requirements before Using the Command Line

You may need to set certain environment variables before using the command line. For more information, see Specifying the Location of Compiler Components with compilervars.

macOS*: Alternatively, you can invoke the compiler with the commands described below using symbolic links in `/usr/local/bin`.

Using the Intel® Fortran Compiler from the Command Line

You can invoke the Intel® Fortran Compiler on the command line using the `ifort` command.

> **NOTE** For Windows* and macOS* systems, you can use the compiler within the IDE.
> For more information on using the Microsoft Visual Studio* IDE, see Using Microsoft Visual Studio*.
> For information on using the Xcode* IDE, see Using Xcode*.

The syntax of the `ifort` command is:

```
ifort [options]input_file(s)
```

The `ifort` command can compile and link projects in one step, or can compile them and then link them as a separate step.

In most cases, a single `ifort` command invokes the compiler and linker. You can also use `ld` (Linux and macOS*) or `link` (Windows*) to build libraries of object modules. These commands provide syntax instructions at the command line if you request it with the `-help` (Linux and macOS*, or the `/help` or `/?` (Windows*) options.

The `ifort` command automatically references the appropriate Intel® Fortran Run-Time Libraries when it invokes the linker. To link one or more object files created by the Intel® Fortran compiler, you should use the `ifort` command instead of the `link` command.

The `ifort` command invokes a *driver program* that is the user interface to the compiler and linker. It accepts a list of command options and file names and directs processing for each file. The driver program does the following:

- Calls the Intel® Fortran Compiler to process Fortran files.
- Passes the linker options to the linker.
- Passes object files created by the compiler to the linker.
- Passes libraries to the linker.
- Calls the linker or librarian to create the executable or library file.

Because the driver calls other software components, they may return error messages. For instance, the linker may return a message if it cannot resolve a global reference. The `watch` option can help clarify which component is generating an error.

For a complete listing of compiler options, see the Compiler Options reference.

NOTE
The compiler recognizes language extensions for offloading in the source program by default and builds a heterogeneous binary that runs on the target and host when any are present. If your program includes these language extensions and you do not want to build a heterogeneous binary, specify the `-no-offload` compiler option. For more information, see the -qno-offload compiler option.

Offload is not supported on Windows systems.

NOTE
Windows systems support characters in Unicode* (multibyte) format. The compiler processes the file names containing Unicode characters.

Syntax Rules

The following rules apply when specifying `ifort` on the command line:

Argument	Description
`options`	An option is specified by one or more letters preceded by a hyphen (`-`) for Linux and macOS* or a slash (`/`) for Windows. (You can use a hyphen (`-`) instead of a slash (`/`) for Windows*, but this is not the preferred method.) Options cannot be combined with a single slash or hyphen, you must specify the slash or hyphen for each option specified. For example: `/1 /c` is correct, but `/1c` is not. Options can take arguments in the form of filenames, strings, letters, and numbers. If a string includes spaces, they must be enclosed in quotation marks. Some options take arguments in the form of filenames, strings, letters, or numbers. Except where otherwise noted, a space between the option and its argument(s) can be entered or combined. For a complete listing of compiler options, see the Compiler Options reference. Some compiler options are case-sensitive. For example, `c` and `C` are two different options. Option names can be abbreviated, enter as many characters as are needed to uniquely identify the option. Compiler options remain in effect for the whole compilation unless overridden by a compiler directive. Certain options accept one or more keyword arguments following the option name on Windows*. To specify multiple keywords, you typically specify the option multiple times. However, some options allow comma-separated keywords. For example: • Options that use a colon can use an equal sign (`=`) instead. • Standard output and standard error can be redirected to a file, avoiding displaying excess text, which slows down execution; scrolling text in a terminal window on a workstation can cause an I/O bottleneck (increased elapsed time) and use more CPU time. See the examples in the next section.

Argument	Description
	NOTE Options on the command line apply to all files. In the following example, the `-c` and `-nowarn` options apply to both files `x.f` and `y.f`: `ifort -c x.f -nowarn y.f`
`input file(s)`	Multipleinput_files can be specified, using a space as a delimiter. When a file is not in PATH or working directory, specify the directory path before the file name. The filename extension specifies the type of file. See Understanding File Extensions.
`Xlinker` (Linux and macOS*) or `/link` (Windows)	Unless specified with certain options, the command line compiles and links the files you specify. To compile without linking, specify the `c` option. All compiler options must precede the `-Xlinker` (Linux and macOS*) or `/link` (Windows*) options. Options that appear following `-Xlinker` or `/link` are passed directly to the linker.

Examples of the ifort Command

The following command compiles `x.for`, links, and creates an executable file. This command generates a temporary object file, which is deleted after linking:

```
ifort x.for
```

The following command compiles `x.for` and generates the object file `x.o` (Linux and macOS*) or `x.obj` (Windows*). The `c` option prevents linking (it does not link the object file into an executable file):

```
//  (Linux and macOS*)
ifort -c x.for
//  (Windows*)
ifort x.for /c
```

The following command links `x.o` or `x.obj` into an executable file. This command automatically links with the default Intel® Fortran libraries:

```
//  (Linux and macOS*)
ifort x.o
//  (Windows*)
ifort x.obj
```

The following command compiles `a.for`, `b.for`, and `c.for`, creating three temporary object files, then linking the object files into an executable file named `a.out` (Linux and macOS*) or `a.exe` (Windows*).

```
ifort a.for b.for c.for
```

Compile the source files that define modules **before** the files that reference the modules (in `USE` statements) when using modules and compile multiple files.

When you use a single `ifort` command, the order in which files are placed on the command line is significant. For example, if the free-form source file `moddef.f90` defines the modules referenced by the file `projmain.f90`, use the following syntax:

```
ifort moddef.f90 projmain.f90
```

To specify a particular name for the executable file, specify the option `-o` (Linux and macOS*) or `/exe` (Windows*):

```
//  (Linux and macOS*)
ifort x.for -o myprog.out
//  (Windows*)
ifort x.for /exe:myprog.exe
```

To redirect output to a file and then display the program output (Linux and macOS*):

```
//  (Linux and macOS*)
myprog > results.lis
more results.lis
```

To place standard output into file `one.out` and standard error into file `two.out`:

```
//  (Windows*)
ifort filenames /options 1>one.out 2>two.out
// OR
ifort filenames /options >one.out 2>two.out
```

To place standard output and standard error into a single file `both.out` (Windows*):

```
//  (Windows*)
ifort filenames /options 1>both.out 2>&1
// OR
ifort filenames /options >both.out 2>&1
```

Other Methods for Using the Command Line to Invoke the Compiler

- **Using makefiles from the Command Line:** Use makefiles to specify a number of files with various paths and to save this information for multiple compilations. For more information on using makefiles, see Using Makefiles to Compile Your Application.
- **Using the devenv Command from the Command Line (Windows Only):** Use `devenv` to set various options for the IDE, and to build, clean, and debug projects from the command line. For more information on the `devenv` command, see the `devenv` description in the Microsoft Visual Studio documentation.
- **Using a Batch File from the Command Line:** Create and use a `.bat` file to consistently execute the compiler with a desired set of options instead of retyping the command each time you need to recompile.

watch
qoffload

Using the Command Line on Windows*

The compiler provides a shortcut to access the command line with the appropriate environment variables already set.

To invoke the compiler from the command line:

- **Windows* 10:**

  1. From the **Start** screen, swipe up from the bottom edge, or click the arrow to move the **Apps** screen.

2. In the **Apps** screen, scroll to the right until you see the program group for your Intel product.
3. Click **Intel 64 Visual Studio mode**, **IA-32 Visual Studio mode**, or **Intel® oneAPI command prompt** to open a command window on your desktop.

- **Older Windows Versions:**

  Click the appropriate mode from the **Start** menu item for your Intel product under **All Programs** > **the product** > **Compiler and Performance Libraries** > **Command Prompt with Intel Compiler**.

  NOTE Older Windows versions are not supported for oneAPI content.

The command line opens.

You can use any command recognized by the Windows command prompt, plus some additional commands.

Because the command line runs within the context of Windows, you can easily switch between the command line and other applications for Windows or have multiple instances of the command line open simultaneously.

When you are finished working in a command line, use the **exit** command to close and end the session.

Running Fortran Applications from the Command Line

For programs run from the command line, the operating system searches directories listed in the PATH environment variable to find the requested executable file.

The program can also be run by specifying the complete path of the executable file. On Windows* operating systems, any DLLs you are using must be in the same directory as the executable or in one specified in the path.

Multithreaded Programs

If the program is multithreaded, each thread starts on whichever processor is available at the time. On a computer with one processor, the threads all run in parallel, but not simultaneously; the single processor switches among them. On a computer with multiple processors, the threads can run simultaneously.

Using the -fpscomp `filesfromcmd` Option

If you specify the `fpscomp` option with keyword `filesfromcmd`, the command line that executes the program can include additional filenames to satisfy `OPEN` statements in the program for which the filename field (`FILE` specifier) has been left blank. The first filename on the command line is used for the first `OPEN` statement executed, the second filename for the second `OPEN` statement, and so on.

NOTE
In the Visual Studio* IDE, you can provide these filenames using **Project** > **Properties**. Choose the Debugging category and enter the filenames in the **Command Arguments** text box.

Each filename on the command line (or in an IDE dialog box) must be separated from the names around it by one or more spaces or tab characters. You can enclose each name in quotation marks ("<*filename*>"), but this is not required unless the argument contains spaces or tabs. A null argument consists of an empty set of quotation marks with no filename enclosed ("").

The following example runs the program `MYPROG.EXE` from the command line:

```
MYPROG "" OUTPUT.DAT
```

Because the first filename argument is null, the first OPEN statement with a blank filename field produces the following message:

```
File name missing or blank - please enter file name
UNIT number  ?
```

The *number* is the unit number specified in the OPEN statement. The filename OUTPUT.DAT is used for the second OPEN statement executed. If additional OPEN statements with blank filename fields are executed, you will be prompted for more filenames.

Instead of using the fpscomp option with keyword filesfromcmd, you can:

- Call the GETARG library routine to return the specified command-line argument. To execute the program in the Visual Studio* IDE, provide the command-line arguments to be passed to the program using **Project** > **Properties**. Choose the Debugging category and enter the arguments in the **Command Arguments** text box.
- On Windows* OS, call the GetOpenFileName Windows* API routine to request the file name using a dialog box.

fpscomp option

Understanding File Extensions

Input File Extensions

The Intel® Fortran Compiler interprets the type of each input file by the file name extension.

The file extension determines if a file gets passed to the compiler or to the linker. The following types of files are used with the compiler:

- Files passed to the compiler: .f90, .for, .f, .fpp, .i, .i90, .ftn

  Typical Fortran source files have a file extension of .f90, .for, and .f. When editing your source files, you need to choose the source form, either free-source form or fixed-source form (or a variant of fixed form called tab form). You can use a compiler option to specify the source form used by the source files (see the description for the free or fixed compiler option) or you can use specific file extensions when creating or renaming your files. For example, the compiler assumes that files with an extension of:

  - .f90 or .i90 are free-form source files.
  - .f, .for, .ftn, or .i are fixed-form (or tab-form) files.
- Files passed to the linker: .a, .lib, .obj, .o, .exe, .res, .rbj, .def, .dll

The most common file extensions and their interpretations are:

Filename	Interpretation	Action
file.a (Linux and macOS*)	Object library	Passed to the linker.
file.lib (Windows)		
file.f	Fortran fixed-form source	Compiled by the Intel® Fortran compiler.
file.for		
file.ftn		
file.i		

Filename	Interpretation	Action

`file.fpp`
On Linux, filenames with the following uppercase extensions:
`file.FPP`
`file.F`
`file.FOR`
`file.FTN`
	Fortran fixed-form source	Automatically preprocessed by the Intel® Fortran preprocessor `fpp`; then compiled by the Intel® Fortran compiler.

`file.f90` `file.i90`	Fortran free-form source	Compiled by the Intel® Fortran compiler.
`file.F90` (Linux and macOS*)	Fortran free-form source	Automatically preprocessed by the Intel® Fortran preprocessor `fpp`; then compiled by the Intel® Fortran compiler.
`file.s` (Linux and macOS*) `file.asm` (Windows)	Assembly file	Passed to the assembler.
`file.o` (Linux and macOS*) `file.obj` (Windows)	Compiled object file	Passed to the linker.

When you compile from the command line, you can use the compiler configuration file to specify default directories for input libraries. To specify additional directories for input files, temporary files, libraries, and for the files used by the assembler and the linker, use compiler options that specify output file and directory names.

Output File Extensions (Windows)

On Windows operating systems, many compiler options allow you to specify the name of the output file being created. These compiler options are summarized in the table below.

If you specify only a filename without an extension, a default extension is added for the file.

Compiler option	Default file extension
/Fa*file*	`.ASM`
/dll:*file*	`.DLL`
/exe:*file*	`.EXE`
/map:*file*	`.MAP`

Invoking the Intel® Fortran Compiler

Using Makefiles to Compile Your Application

This topic describes the use of makefiles to compile your application. You can use makefiles to specify a number of files with various paths, and to save this information for multiple compilations.

Using Makefiles to Store Information for Compilation on Linux* or macOS*

To run `make` from the command line using the Intel®Fortran Compiler, make sure that `/usr/bin` and `/usr/local/bin` are in your *PATH* environment variable.

If you use the C shell, you can edit your `.cshrc` file and add the following:

```
setenv PATH /usr/bin:/usr/local/bin:$PATH
```

Then you can compile using the following syntax:

```
make -f yourmakefile
```

Where `-f` is the `make` command option to specify a particular makefile name.

Using Makefiles to Store Information for Compilation on Windows*

To use a makefile to compile your source files, use the `nmake` command . For example, if your project is `your_project.mak`, you can use the following syntax:

```
nmake /f [makefile_name.mak] FPP=[compiler_name.exe] LINK32=[linker_name.exe]
```

For example:

```
prompt> nmake /f your_project.mak FPP=ifort.exe LINK32=xilink.exe
```

Argument	Description
`/f`	The `nmake` option to specify a makefile.
`your_project.mak`	The makefile used to generate object and executable files.
`FPP`	The preprocessor/compiler that generates object and executable files. (The name of this macro may be different for your makefile.)
`LINK32`	The linker that is used.

The `nmake` command creates object files (`.obj`) and executable files (`.exe`) from the information specified in the `your_project.mak` makefile.

Generating Build Dependencies for Use in a Makefile

Use the `gen-dep` compiler option to generate build dependencies for a compilation.

Build dependencies include a list of all files included with `INCLUDE` statements and `.mod` files accessed with `USE` statements. The resulting output can be used to create a makefile to with the appropriate dependencies resolved.

Consider a source file that contains the following:

```
 module b
 include 'gendep001b.inc'
 end module b

 program gendep001
 use b
 a_global = b_global
end
```

When you compile the source using the `gen-dep` option, the following output is produced:

```
b.mod : \
 gendep001.f90
gendep001.obj : \
 gendep001.f90 gendep001b.inc
```

This output indicates that the generated file, `b.mod`, depends on the source file, `gendep001.f90`. Similarly, the generated file, `gendep001.obj`, depends on the files, `gendpe001.f90` and `gendep001b.inc`.

Using Microsoft Visual Studio* (Windows*)

You can use the Intel® Fortran Compiler within the Microsoft Visual Studio* integrated development environment (IDE) to develop Fortran applications, including static library (`.LIB`), dynamic link library (`.DLL`), and main executable (`.EXE`) applications. This environment makes it easy to create, debug, and execute programs. You can build your source code into several types of programs and libraries, using the IDE or from the command line.

The IDE offers these major advantages:

- Makes application development quicker and easier by providing a visual development environment.
- Provides integration with the native Microsoft Visual Studio* debugger.
- Makes other IDE tools available.

Performing Common Tasks with Microsoft Visual Studio*
Using Microsoft Visual Studio* Solution Explorer
Using Breakpoints in the Debugger

Using Microsoft Visual Studio* Solution Explorer

After starting Microsoft Visual Studio*, a screen appears. This shows an open **Solution** named `Console1`, a **Project** named `Console1`, and the **source file**`Console1.f90` have been opened. The right pane shows the file `Console1.f90`, opened in the default language-sensitive integrated development environment text editor, which uses different colors to identify the following:

- Source comments (green)
- Fortran standard language elements (blue)
- Other language text (black)

Solution Explorer View

The left pane shows the **Solution Explorer** view, which lets you view different aspects of your solution, such as the source files in your solution. The tabs displayed in **Solution Explorer** vary depending upon the products installed and the files associated with the current solution. The sample screen shown above shows a **Solution** tab and a **Property Manager** tab (not used by Intel® Fortran). To display the **Solution Explorer** view, select **View** > **Solution Explorer**.

To edit a file listed in **Solution Explorer**, either double-click its file name or select **File** > **Open** and specify the file.

The **Output** window displays compilation and linker messages. To display the **Output** window, select **View** > **Output**. The **Output** window also links to the build log, if the **Generate Build logs** option is enabled in **Tools** > **Options** > **Intel Compilers and Tools** > **Visual Fortran**.

Creating a New Project

Creating a New Project

When you create a project, Microsoft Visual Studio* automatically creates a corresponding solution to contain it. To create a new Intel® Fortran project using Microsoft Visual Studio*:

The `hello32` project assumes focus in the **Solution Explorer** view. The default Microsoft Visual Studio* solution is also named `hello32`

1. Select **File** > **New** > **Project**.
2. In the left pane, click **Intel® Visual Fortran** to display the Fortran project types. For each project type, available templates are listed in the right pane.
3. Click the appropriate project type (see Understanding Project Types).
4. Accept or specify a project name.
5. Accept or specify the Location for the project directory. Project files will be stored here. If the directory specified does not exist, it will be created.
6. Click **OK** to complete the new project.

The project and its files appear in the **Solution Explorer** view. For a COM Server project, you will see a second page with additional user options.

Add an Existing File to the Project

1. If not already open, open the project (use the **File** menu).
2. Select **Project** > **Add Existing Item**.
3. In the **Add Existing Item** dialog box that appears, select the Fortran files to be added to the project.

Add a New File to the Project

1. If not already open, open the project (use the **File** menu).
2. Select **Project** > **Add New Item**.
3. In the **Add New Item** dialog box that appears, choose the type of file.
4. Specify the file name. Click **Open**. The file name appears in the **Solution Explorer** view.
5. Use the Microsoft Visual Studio* editor to type in source code. Be sure to save your work when you are finished.

Organizing Existing Source Code

If you have existing source code, you should organize it into directories before creating a project, although it is easy to move files and edit your project definitions if you should later decide to reorganize your files.

Working with Fortran Modules

If your program uses Fortran modules, you do not need to explicitly add them to your project; they appear as dependencies (`.MOD` files).

A module file is a precompiled, binary version of a module definition, stored as a `.mod` file. When you change the source definition of a module, you can update the `.mod` file before you rebuild your project. To do this, compile the corresponding source file separately by selecting the file in the **Solution Explorer** window and selecting **Build** > **Compile**. If the module source file is part of your project, you do not need to compile the file separately. When you build your project, the Intel® Fortran Compiler determines what files need to be compiled.

To control the placement of module files in directories, use **Project** > **Properties** > **Fortran** > **Output Files** > **Module Path** in the IDE or the compiler option `[no]module` on the command line. The location you specify is automatically searched for `.mod` files.

To control the search for module files in directories, select one of the following:

- **In the IDE:**
  - **Project** > **Properties** > **Fortran** > **Preprocessor** > **Default Include and Use Path**
  - **Project** > **Properties** > **Fortran** > **Preprocessor** > **Ignore Standard Include Path**
- **On the Command Line:**
  - `X` or `I` and `assume:source_include` compiler options.

For a newly created project (or any other project), the IDE scans the file list for sources that define modules and compiles them before compiling the program units that use them. The IDE automatically scans the added project files for modules specified in `USE` statements, as well as any `INCLUDE` statements. It scans the source files for all tools used in building the project.

Performing Common Tasks with Microsoft Visual Studio*

This topic outlines the basic steps for using the Intel® Fortran Compiler with Microsoft Visual Studio*.

Building and Running a Fortran Project

- To build the application, select **Build** > **Build Solution**. Any errors will be displayed in the **Output Window**. Double-click on a message to go to the line in error.
- To run without debugging, select **Debug** > **Start Without Debugging**. The console window will remain open after the program exits until you press Enter.
- To run under the debugger, first set a breakpoint at the first executable line of the program by clicking in the gray column to the left of the source line. Then select **Debug** > **Start**. If the program exits normally, the console window will be closed automatically.

Converting Compaq* Visual Fortran Projects

For information on converting projects from Compaq* Visual Fortran to Intel® Fortran, see Converting Projects.

Creating a New Project
Converting Projects

Selecting a Version of the Intel® Compiler

If you have more than one version of the Intel® Fortran Compiler installed, you can choose which version to be used when building applications. You can also select different versions for different target platforms and the version of the compiler you are using. The target platform you select determines the compiler versions that appear in the **Selected** drop-down box.

To select the compiler version:

1. Select **Tools** > **Options** > **Intel Compilers and Tools** > **Visual Fortran** > **Compilers**.
2. Select a compiler from **Selected compiler**. Click **OK**.

See Also

Specifying a Target Platform for Solutions and Projects

Specifying Fortran File Extensions

You can specify additional Fortran free format and fixed format file extensions to be recognized as valid file extensions within the IDE. The IDE treats these additional extensions as compilable Fortran source files. You can also remove or modify existing extensions.

When you add a new extension, the IDE checks the registry to determine whether the extension is already associated with a language, tool, or file format. If there is such an association, a message informs you of this and you will not be allowed to add the extension.

To specify Fortran file extensions:

1. Open **Tools** > **Options**.
2. In the left pane, go to **Intel Compilers and Tools** > **Visual Fortran** > **General**.
3. Specify one or more Fortran File Extensions, each beginning with a period and separated by semi-colons. You can specify extensions for both **Free Format** and **Fixed Format**. Click **OK**.

These new settings take effect the next time you start Visual Studio*.

Use the **Reset** button to restore Fortran file extensions to their default settings.

Understanding Solutions, Projects, and Configurations

The Microsoft* Visual Studio* integrated development environment (IDE) consists of one or more projects contained within a **solution**. A solution can contain multiple projects. For example, if you have several Fortran applications that do different calculations, but are related to the same research application you are working on, you can store all the individual projects in a single solution. Along with a solution file (`.sln`), the IDE creates a solution user options (`.suo`) file for storing IDE customization.

The following table summarizes the files created by Microsoft* Visual Studio* when a new project is created:

File	Extension	Description
Project Solution file	`.sln`	Stores solution information, including the projects and items in the solution and their locations on disk.
Project file	`.vfproj` `.vcxproj`	Contains information used to build a single project or sub-project.
Solution options file	`.suo`	Contains IDE customization for the solution, based on the selected options.

Caution
Directly modifying these files with a text editor is not supported.

Caution
Before opening Compaq* Visual Fortran 6.0 projects or Intel® Visual Fortran 7.x projects in Microsoft* Visual Studio*, review the guidelines listed in Converting Projects.

Each project can specify one or more configurations to build from its source files. A configuration specifies such information as the type of application to build, the platform it runs on, and the tool settings to use when building. Having multiple configurations extends the scope of a project, but maintains a consistent source code base to work with.

Microsoft* Visual Studio* automatically creates **Debug** and **Release** (also known as **Retail**) configurations when a new project is started. The default configuration is the **Debug** configuration. To specify the current configuration, select **Configuration Manager** from the **Build** menu.

Specify build options in the **Project** > **Properties** dialog box, for one of the following:

- For all configurations (project-wide)
- For certain configurations (per configuration)
- For certain files (per file)

For example, specify compiler optimizations for all general configurations, but turn them off for certain configurations or certain files.

Once the files in the project are specified and the configurations for your project build are set, including the tool settings, build the project with the commands on the **Build** menu.

> **NOTE**
> For a multiple-project solution, make sure that the executable project is designated as the startup project (shown in bold in the **Solution Explorer** view). To modify the startup project, right click on the project and select **Set as StartUp Project**.

Converting Projects

Navigating Programmatic Components in a Fortran File

You can quickly navigate the code of the file currently open in the source editor using the **Tree Navigation Window**. The **Tree Navigation Window** displays the following components of the file as nested, selectable nodes in a tree:

- Programs
- M odules
- Subroutines with signature
- Functions with signature
- Types
- Interfaces

Nodes at each nested level are sorted alphabetically.

Any changes you make to a file, such as adding or deleting a component or changing a signature, are immediately reflected in the tree.

To navigate a file:

1. Select **View** > **Other Windows** > **Tree Navigation Window**.
   The **Tree Navigation Window** tab appears near the **Solution Explorer** tab. When no Fortran project is opened, the **Tree Navigation Window** is empty. When you open a Fortran file in the source editor, all components of the file appear in the window.
2. Select a node in the tree to view the corresponding component in the source editor.
   The cursor appears at the correct location in the file.

Selecting a Configuration

A configuration contains settings that define the final binary output file that you create within a project. It specifies the type of application to build, the platform on which it is to run, and the tool settings to use when building.

Debug and Release Configurations

When you create a new project, Visual Studio* automatically creates the following configurations:

Configuration	Description
Debug configuration	By default, the debug configuration sets project options to include the debugging information in the debug configuration. It also turns off optimizations. Before you can debug an application, you must build a debug configuration for the project.
Release (Retail) configuration	The release configuration does *not* include the debugging information, and it uses any optimizations that you have chosen.

Use the Visual Studio* **Configuration Manager** to select:

- **Release** or **Debug** configuration for the active solution.
- **Release** or **Debug** configuration for any project within the active solution.
- Target platform for each project.

Multiple configurations allow extending the scope of a project while maintaining a consistent source code base from which to work. The default configuration is the **Debug** configuration. To add, change, or delete a configuration, select **Build** > **Configuration Manager** from the main menu or use the drop-down box on the main menu bar. Only one configuration can be active at one time. Configurations can be used for the whole solution or for specific projects in the solution.

When you build your project, the currently selected configuration is built, as follows:

- If you selected the debug configuration, a directory called `Debug` contains the output files created by the build for the debug version of your project.
- If you selected the release configuration, a directory called `Release` contains the output files created by the build for the release version of your project.

(You can change the output directory using the **General** category in **Project** > **Properties**.)

A configuration has the following characteristics:

- **Configuration type:** specifies the type of Fortran application to build.
- **Build options:** specifies the build options, which include the compiler and linker options.

By default, the **Debug** configuration sets project options to include debug symbol information and turns off optimizations. Before you can debug an application, you must build a debug configuration for the project. Although debug and release configurations usually use the same set of source files, the project setting information usually differs. For example, the default debug configuration supplies full debug information and no optimizations, whereas the default release configuration supplies minimal debug information and full optimizations.

To make configuration changes for your project:

1. Choose an active solution in the **Solution Explorer**.
2. Go to **Build** > **Configuration Manager**.
3. Select a configuration.

Platform Types

The platform type sets options required specifically for the selected platform, such as options that the compiler uses for the source files, the libraries that the linker uses for the platform, defined constants, and so on.

New Configurations

In addition to the default **Debug** and **Release** configurations, you can also define new configurations within your project. These configurations may use the existing source files in your project, the existing project settings, or other characteristics of existing configurations.

See Also

Setting Compiler Options in the Visual Studio* IDE Property Pages
Specifying a Target Platform for Solutions and Projects
Understanding Errors During the Build Process

Specifying a Target Platform

You can specify a target platform for a Microsoft Visual Studio* solution or an individual project within a solution.

1. Select a solution or project in the **Solution Explorer**.
2. Select **Build** > **Configuration Manager**.
   - Use the **Active solution platform** drop-down list to specify the target platform for the whole solution.
   - Use the **Platform** column to specify the target platform for an individual project within a solution.
3. Select **<New...>** on the **Active solution platform** drop-down menu to add a platform to the current list of active solution platforms.
4. Select or type a new platform in the **New Solution Platform** dialog box.
5. In **Copy settings from** choose a platform to use as a template or choose **<Empty>**.
6. If you want the platform to be set for the projects within the solution, select **Create new project platforms**. Click **OK**.
7. Close the **Configuration Manager**.

NOTE You can also change target platforms from the Microsoft Visual Studio* toolbar by selecting a platform from the **Solution Platforms** drop-down selection.

Removing Target Platforms

You can remove a target platform from the **Configuration Manager**:

1. Select **<Edit...>** from the **active solution platform** list of options.
2. In the **Edit Solutions Platforms** dialog that opens, select a platform and click **Remove**.
3. Click **Yes** in the confirmation box.

Specifying Path, Library, and Include Directories

You can specify directories that the Microsoft Visual Studio* project system should search for certain types of files.

To set path, library, and include directories for your Intel® Fortran project environment on a particular machine:

1. Select **Tools** > **Options**.
2. In the left pane, select **Intel Compilers and Tools** > **Visual Fortran** > **Compilers**.
3. In the right pane, specify directories where the Microsoft Visual Studio* project system should look for files:
   - **Executables:** The directories to be searched for executable files. (Works like the PATH environment variable.)
   - **Libraries:** The directories to be searched for libraries. (Works like the LIB environment variable.)
   - **Includes:** The directories to be searched for include files. (Works like the INCLUDE environment variable.) You can use macros like `$(VSInstallDir)` in directory names. For list of supported macros, see Supported Build Macros.
4. Click **OK**.

Use the **Reset** and **Reset All** buttons to restore original installation settings for Executables, Libraries, and Includes fields. **Reset** restores initial settings for the currently selected compiler; **Reset All** restores initial settings for all compilers listed in the **Selected** drop-down box.

> **NOTE** If you specify `devenv` or `useenv` on the command line to start the IDE, the IDE uses the PATH, INCLUDE, and LIB environment variables as defined for that command line when performing a build. It uses these values instead of the values defined in **Tools** > **Options**.
> For more information on the `devenv` command, see the `devenv` description in the Microsoft Visual Studio* documentation.

For more information on environment variables, see Supported Environment Variables.

Supported Environment Variables

Supported Build Macros

Setting Compiler Options in the Microsoft Visual Studio* IDE Property Pages

To set compilation and related options for the current project:

1. Select the project name in the **Solution Explorer** view.
2. In the **Project** menu, select **Properties**.

The Intel® Fortran Compiler also lets you specify compiler options for individual source files. To do this, select the file name and select **View** > **Property Pages**.

> **NOTE** For convenience, context-sensitive pop-up menus containing commonly used menu options are available by right-clicking on an item (for example, a file name or solution) in the IDE.

Displaying the Options

To display the Fortran compiler option categories, click the **Fortran** folder in the left pane to display the compiler option categories. The following sample screen shows the compiler options in the **General** category in the right pane. The selected option within the **General** category is **Suppress Startup Banner**, with a default value of Yes. The corresponding command line compiler option is `nologo`, as shown in the **Help** text at the bottom of the right pane.

> **NOTE** Option values that are different than the compiler defaults are displayed in bold.

Changing Option Settings

To change the setting for a compiler option:

1. Select a category and then click the desired option. Click the button at the right of an option line to display the available settings or display a dialog box. Available settings may include ***<inherit from project defaults>***, which resets the option value to the compiler default.
2. Select the desired setting and click **OK**.

To change the configuration (such as from **Debug** to **Release**), do one of the following:

- Select a different configuration in the **Configuration:** drop-down box in the upper-left of the window, or
- Click the **Configuration Manager** button in the upper-right of the window and reset the configuration in the dialog box that appears.

Fortran Option Categories

The Intel® Fortran compiler options available from the IDE are grouped in categories. Some options appear in multiple categories. Available options in each category may vary, depending the platform you have selected in the **Platform** box at the top of the dialog box. Options not listed in one of the categories can be typed into the **Command Line** category window.

Command Line Category

The **Command Line** category contains the **Additional Options** field where you can type in an option as you would from the command line. The IDE will process them as part of the **Property Pages** options for the particular project. For instance, you can use the **Command Line** category to type in miscellaneous Intel® Fortran compiler options that are not represented in any of the listed categories. If you type in a compiler option that is represented in one of the listed categories, the option you specify in the **Command Line** category will take precedence and override the equivalent setting in another category.

Supported Build Macros

The Intel® Fortran compiler supports certain build macros for use in the **Property Pages** dialog boxes associated with a project. Use these macros where character strings are accepted. The macro names are not case-sensitive.

The following table lists macros supported by Visual Studio* that are also supported by the Intel® Fortran Compiler.

Macro Name	Format
Configuration name	`$(ConfigurationName)`
Platform name	`$(PlatformName)`
Intermediate directory	`$(IntDir)`
Output directory	`$(OutDir)`
Input directory	`$(InputDir)`
Input path	`$(InputPath)`
Input name	`$(InputName)`
Input filename	`$(InputFileName)`
Input file extension	`$(InputExt)`
Inherit properties	`$(Inherit)`
Do not inherit properties	`$(NoInherit)`
Project directory	`$(ProjectDir)`
Project path	`$(ProjectPath)`
Project name	`$(ProjectName)`
Project filename	`$(ProjectFileName)`
Project file extension	`$(ProjectExt)`

Macro Name	Format
Solution directory	`$(SolutionDir)`
Solution path	`$(SolutionPath)`
Solution name	`$(SolutionName)`
Solution filename	`$(SolutionFileName)`
Solution file extension	`$(SolutionExt)`
Target directory	`$(TargetDir)`
Target path	`$(TargetPath)`
Target name	`$(TargetName)`
Target filename	`$(TargetFileName)`
Target file extension	`$(TargetExt)`
Visual Studio* installation directory	`$(VSInstallDir)`
Visual C++* installation directory	`$(VCInstallDir)`
.NET Framework directory	`$(FrameworkDir)`
.NET Framework version	`$(FrameworkVersion)`
.NET Framework SDK Directory	`$(FrameworkSDKDir)`

The Intel® Fortran compiler also supports the following macros (not supported by Visual Studio*).

Macro Name	Format
Intel® Fortran IDE installation directory	`$(IFIDEInstallDir)`

For additional information on using build macros, see the Microsoft MSDN* online documentation.

Using Manifests

The Intel® Fortran Compiler supports manifests, a Visual Studio* feature. Manifests describe run-time dependencies of a built application. A manifest file can be embedded in the assembly, which is the default behavior, or can be a separate standalone file. You can use the **Manifest Tool** property pages, which are accessed through **Project** > **Properties**, to change project settings that affect the manifest.

NOTE
In earlier releases, manifest files were embedded in the assembly, and were not able to be accessed or changed.

Using Intel® Performance Libraries with Microsoft Visual Studio*

You can use the Intel®Fortran Compiler with the following Intel® Performance Libraries that may be included as a part of the product:

- Intel® Integrated Performance Primitives (Intel® IPP)
- Intel® Threading Building Blocks (Intel® TBB)
- Intel® Math Kernel Library (Intel® MKL)

Use the property pages to specify Intel® Performance Libraries to use with the selected project configuration.

To specify Intel® Performance Libraries, select **Project** > **Properties**. In **Configuration Properties**, select **Intel Performance Libraries**, then do the following:

1. To use **Intel® Integrated Performance Primitives**, change the **Use Intel IPP** settings as follows:
   - **No:** Disable use of Intel® IPP libraries.
   - **Default Linking Method:** Use Intel® IPP libraries that depend on the settings for the **Code Generation** > **Runtime Library** property.
   - **Multi-threaded Static Library:** Use parallel static Intel® IPP libraries.
   - **Single-threaded Static Library:** Use parallel sequential static Intel® IPP libraries.
   - **Multi-threaded DLL:** Use parallel dynamic Intel® IPP libraries.
   - **Single-threaded DLL:** Use parallel sequential static Intel® IPP libraries.
2. To use **Intel® Threading Building Blocks** in your project, change the **Use Intel TBB** settings as follows:
   - **No:** Disable use of Intel® TBB libraries.
   - **Use TBB:** Set to **Yes** to use Intel® Threading Building Blocks.
   - **Instrument for use with Intel® Threading Analysis Tools:** Set to **Yes** to add the preprocessor definition TBB_USE_THREADING_TOOLS to the project property **Preprocessor** > **Preprocessor Definitions**.

   NOTE The TBB_USE_THREADING_TOOLS definition will be added only if the project property **Code Generation** > **Runtime Library** is set to **Multi-threaded DLL (option `MD`)**.

3. To use **Intel® Math Kernel Library** in your project, change the **Use Intel MKL** property settings as follows:
   - **No:** Disable use of Intel® MKL libraries.
   - **Parallel:** Use parallel Intel® MKL libraries.
   - **Sequential:** Use sequential Intel® MKL libraries.
   - **Cluster:** Use cluster Intel® MKL libraries.

   If your target platform is set to **x64**, a final selection appears: **Use ILP64 interfaces**. If selected, the corresponding ilp MKL libraries is added to the linker command line. Additionally, the MKL_ILP64 preprocessor definition is added to the compiler command line. If you do not make this selection, lp MKL libraries are used.

   NOTE Sets of libraries for each option depend on selected target platform and project properties defined by **Code Generation** > **Runtime Library** and **Advanced** > **Calling Convention**.

For more information, see the Intel® Integrated Performance Primitives, Intel® Threading Building Blocks, and Intel® Math Kernel Library documentation.

Optimization Notice
Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice. Notice revision #20110804

Using Guided Auto Parallelism in Microsoft Visual Studio*

The Guided Auto Parallelism (GAP) feature helps you locate portions of your serial code that can be parallelized. When you enable analysis using GAP, the compiler guides you to places in your code where you can increase efficiency through automatic parallelization and vectorization.

Running Analysis on a Project

You can start analysis from the Microsoft Visual Studio* IDE in several ways:

- From the **Tools** menu: Select **Intel Compiler** > **Guided Auto Parallelism** > **Run Analysis...**

  Starting analysis in this way results in a one-time run for the current project. The default values are taken from **Tools** > **Options** unless you have chosen to override them in the dialog box.
- From the Diagnostics property page: Use the **Guided Auto Parallelism Analysis** property.

  Specifically, choose **Project** > **Properties** > **Fortran** > **Diagnostics** and enable analysis using the **Guided Auto Parallelism Analysis** property. Enabling analysis in the property page allows you to run an analysis as part of a normal project **Build** request in Microsoft Visual Studio*. In this mode, GAP-related settings in **Tools** > **Options** are ignored, in favor of other GAP-related settings available in the property page.
- From the context menu: Right-click and select **Intel Compiler** > **Guided Auto Parallelism** > **Run Analysis...**.

  This is equivalent to using the **Guided Auto Parallelism** > **Run Analysis** option on the **Tools** menu.

To receive advice for auto parallelization, be sure that certain property page settings are correct. Select **Project** > **Properties** > **Fortran** > **Optimization** and set **Parallelization** to **Yes** to enable auto-parallelization optimization. You may also need to set the **Optimization** level at option `O2` or higher.

GAP Scenarios

To illustrate how the various GAP settings work together, consider the following scenarios:

Scenario	Result
The GAP analysis setting in the property pages is set to Enabled.	Analysis always occurs for the project, whenever a regular project build occurs. Other analysis settings specified in the property pages are used. Analysis setting in **Tools** > **Options** are ignored.
The Gap analysis setting in the property pages is set to Disabled, and GAP is run from the **Tools** menu.	Analysis occurs for this one run. The default values for this analysis are taken from **Tools** > **Options** and can be overridden in the dialog box. Options specified in the property pages are also used, but will be overridden by any specified analysis option.

Scenario	Result
The GAP analysis setting in the property pages is set to Disabled, and GAP options are set in **Tools** > **Options**.	No analysis occurs, unless analysis is explicitly run from the **Tools** menu.

Running Analysis on a File or within a File

Right-click on **Guided Auto Parallelism** context menu item to run analysis on the following:

- **Single file:** Select a file and right-click.
- **Function (routine):**Right-click within the function scope.
- **Range of lines:** Select one or more lines for analysis and right-click.

Using Guided Auto Parallelism

Using Code Coverage in Microsoft Visual Studio*

The code coverage tool provides the ability to determine how much application code is executed when a specific workload is applied to the application. The tool analyzes static profile information generated by the compiler, as well as dynamic profile information generated by running an instrumented form of the application binaries on the workload. The tool can generate a report in HTML-format and export data in both text- and XML-formatted files. The reports can be further customized to show color-coded, annotated source-code listings that distinguish between used and unused code.

To start code coverage:

1. Select **Tools** > **Intel Compiler** > **Code Coverage...**
2. Specify settings for the various phases.
3. Click **Run**.

The **Output** window shows the results of the coverage and a general summary of information from the code coverage.

Code Coverage Settings dialog box

Code Coverage Tool

Using Profile Guided Optimization in Microsoft Visual Studio*

Profile Guided Optimization (PGO) improves application performance by reorganizing code layouts to reduce instruction-cache problems, shrinking code size, and reducing branch misprediction. PGO provides information to the compiler about areas of an application that are most frequently executed. By knowing these areas, the compiler is able to be more selective and specific in optimizing the application.

To start PGO:

1. Choose **Tools** > **Intel Compiler** > **Profile Guided Optimization...**
2. Specify settings for the various phases.
3. Click **Run**.

The **Output** windows show the results of the optimization with a link to the composite log.

Using Source Editor Enhancements in Microsoft Visual Studio*

A number of Fortran source editor enhancements are available in Microsoft Visual Studio*.

Modules and Procedures Navigation Bar

A two-part navigation bar, located above the source editor pane, lets you navigate to a specific module (left part) and procedure (right part). To enable the navigation bar, choose **Navigation Bar** in **Tools** > **Options** > **Text Editor** > **Fortran** > **General**.

Source Editor Pane

Smart indenting: Smart indenting automatically indents block constructs (such as `IF` and `DO`) and left justifies the corresponding end statement. To enable smart indenting, select it in **Tools** > **Options** > **Text Editor** > **Fortran** > **Tabs**.

Code snippet insertion: Code snippet insertion lets you insert a prototype construct (such as `DO`, `WHILE`, or `MODULE`) from a list. Use the right-click context menu **Insert Snippet... option** to display the list and insert a snippet.

Delimiter matching: Delimiter (brace) matching lets you jump to a matching statement in a block construct (`IF...THEN...END IF`, `DO...END DO`). Use Ctrl] to jump. To enable delimiter matching, use **Automatic delimiter highlighting** in **Tools** > **Options** > **Text Editor** > **General**.

Call/Callers graph: Call/Caller information can be collected and shown visually in a graph that indicates the call stacks that lead to a unit of code. To enable Call/Callers graph information, change **Collect Call/Callers graph information** to **True** in **Tools** > **Options** > **Text Editor** > **Fortran** > **Advanced** > **Browsing/Navigation**.

Fortran Editor Options Page

Use **Tools** > **Options** > **Text Editor** > **Fortran** > **Advanced** to view the Fortran Advanced Options page.

Browsing/Navigation Section

Collect Object Browser information: Choose this option to enable the display of procedures in your project in a hierarchical tree. Once enabled, you can use **View** > **Object Browser** to display your procedures.

NOTE If the procedures in your project do not show when browsing in **My Solution**, you can right-click the message (No information. Try browsing a different component set.) and select **View Containers** as a possible solution.

Disable Database: Choose this option to disable creation of the code browsing database. This may help increase performance on slow machines. If you disable the database, all features that rely on code browsing information will not work.

Enable Find all References: Choose this option to enable display of the location(s) in your code where a symbol is referenced. When this option is enabled, you can use the right-click context menu **Find All References** option to display a list of references to the selected symbol. Double-click on a reference to find that reference.

Enable Go To Definition: Choose this option to enable quick navigation to an object definition. When this option is enabled, you can use the right-click context menu **Go to Definition** option to locate where the selected object was declared, opening the associated source file if required. (If you have also enabled **Scan system includes**, any objects declared in system modules such as IFWINTY cause the associated source for that module to be opened.)

Scan system includes: Choose this option to scan system include files. This option is used with one or more of the following options: **Collect Object Browser Information**, **Enable Find All References**, **Enable Go To Definition**.

Intrinsics Section

Enable Intrinsic Parameter Info: Choose this option to enable the display of intrinsic function and subroutine parameter information. When this option is enabled, you can type a name of an intrinsic procedure, followed by an open parenthesis, and information about the procedure and its arguments appears.

Enable Intrinsic Quick Info: Choose this option to enable the display of additional information when the mouse pointer is moved over an intrinsic function or subroutine name.

Miscellaneous Section

Enumerate Comment Tasks: Choose this option to enable the display of a list of tasks consisting of source files containing comments. Comments take the form of the ! character, followed by a token such as TO DO. Valid tokens are those listed in **Tools** > **Options** > **Environment** > **Task List**. When this option is enabled, you can select **Comments** from the task list using **View** > **Other Windows Task List**. Double-click on a comment in the list to jump to its location.

Highlight Matching Tokens: Choose this option to allow identifier highlighting and block delimiter matching. When enabled, this option highlights all references to the identifier under the cursor.

Outlining Section

Enable Outlining: Choose this option to allow the collapsing of whole program units. When this option is enabled, you can click the minus (-) or plus (+) symbols for `PROGRAM`, `SUBROUTINE`, `FUNCTION`, `MODULE`, and `BLOCK DATA` statements.

Outline Statement Blocks: Choose this option to allow collapsing of block constructs such as `IF` and `DO`. You must also choose **Enable Outlining**.

Creating the Executable Program

When you are ready to create an executable image of your application, use the options on the **Build** menu. You can:

- Compile a file without linking.
- Build a project or solution.
- Rebuild a project or solution.
- Batch build several configurations of a project.

- Clean a project or solution (which deletes all files created during the Build).
- Select the active solution and configuration.
- Edit the project configuration.

When you have completed your project definition, you can build the executable program.

When you select **Build <*projectname*>** from the **Build** menu (or **Build** toolbar), the integrated development environment (IDE) automatically updates dependencies, compiles and links all files in your project. When you build a project, the IDE processes only the files in the project that have changed since the last build and those files dependent on the changed files. The following example illustrates this.

> **NOTE** To define the build order of projects, right-click on the solution and choose **Properties** > **Project Dependencies**.

Example: Assume you have multiple projects (A, B, and C) in a solution with the following defined dependencies:

- A depends on B
- B depends on C

If you build A, the build process verifies that B is up-to-date. During verification of B, C is also verified that it is likewise up-to-date. When either, or both, are determined to be out of date, the appropriate build operations will occur to update them. When C and B produce `.lib` or `.dll` output, the output of C is linked into B and the output of B is linked into A.

The **Rebuild <*project name*>** option forces a new compilation of all source files listed for the project.

You either can choose to build a single project, the current project, or multiple project configurations (using the **Batch Build...** option) in one operation. You can also choose to build the entire solution.

You can execute your program from the IDE using **Debug** > **Start Without Debugging** (Ctrl and F5) or **Debug** > **Start** (F5). You can also execute your program from the command line prompt.

Compiling Files in a Project

You can select and compile individual files in any project in your solution. To do this, select the file in the **Solution Explorer** view. Then, do one of the following:

- Select **Compile** from the **Build** menu (or **Build** toolbar).
- Right-click to display the pop-up menu and select **Compile**.

You can also use **Compile** from the **Build** menu (or **Build** toolbar) options when the source window is active and has input focus.

Encountering Errors during Compilation

When the compiler encounters an error in a file, compilation stops and the error is reported. You can change this default behavior and allow compilation to continue despite an error in the current file. When you do this, an error in the current file will cause the compiler to begin compiling the next file.

To enable **Continue on errors** behavior:

1. In **Tools** > **Options** > **Intel Compilers and Tools** > **Visual Fortran**, select the **General** category.
2. Check **Continue on errors** and click **OK**.

To set the maximum number of errors to encounter before compilation stops, choose **Configuration Properties** > **Fortran** > **Diagnostics** > **Error Limit**.

Performing Parallel Project Builds

Visual Studio* provides a parallel project build feature, allowing you to build multiple projects within a solution simultaneously, using separate threads. The Visual Studio* IDE initially sets the number of parallel project builds to equal the number of CPUs. To change this setting, do the following:

1. Choose **Tools** > **Options** > **Projects and Solutions**.
2. In the **Build and Run** property page, change the number in maximum number of parallel project builds and click **OK**.

For more information on using this feature, see the Microsoft MSDN* documentation.

Converting and Copying Projects

Converting Projects

In general, you can open projects created by older versions of Intel® Visual Fortran and use them directly. If the projects were created in older versions of Microsoft Visual Studio*, the solution file is converted first and then any non-Fortran projects it contains. Projects created in newer versions of Intel® Visual Fortran might not be usable in older versions.

Projects created in Compaq* Visual Fortran 6.0 or later can usually be converted to Intel® Visual Fortran as follows:

1. Open the Microsoft Visual Studio* 6 workspace file (.dsw) in a newer version of Microsoft Visual Studio*. The project is converted to the new format.
2. Right click on the solution and select `Extract Compaq Visual Fortran Project Items`. This option is available only if your installation of Microsoft Visual Studio* includes Microsoft Visual C++.

Some general conversion principles apply:

- It is good practice to make a backup copy of the project before starting conversions.
- Intel® Fortran projects are created and built in a particular version of Microsoft Visual Studio*. If you open the project in a later version, you will be prompted to convert the solution. Once converted, a solution cannot be used in its previous environment.
- Compaq* Visual Fortran 6.x projects can be converted to Intel® Fortran projects in Microsoft Visual Studio* 2013, 2015, or 2017 environments. Fortran-only projects are simpler to convert.
- Project conversion support is provided for Compaq* Visual Fortran Version 6.x only. Compaq* Visual Fortran projects created with earlier versions may not convert correctly.
- Fortran source files, resource files, and `MIDL` files lose any custom build step information when converted from Compaq* Visual Fortran to Intel® Fortran. For other file types, custom build steps are propagated during the project's conversion.
- Conversion of Fortran and C/C++ mixed language projects results in the creation of two separate projects (a Fortran project and a C/C++ project) in a single solution.
- Intel® Fortran projects that are created with a point release (for instance, 18.x) are typically backward compatible to the first release of that number (in this case, 18.0). Projects are not backward-compatible between major release numbers.

See Also

Copying Projects

Copying Projects

You need to follow certain procedures to move a project's location if you copy a project to:

- Another disk or directory location on the same system.
- Another system where the Intel® Fortran Compiler is installed.

If you upgrade your operating system version on your current system, you should delete the `*.SUO` and `*.NCB` files in each main project directory before you open solutions with the new operating system.

It is good practice to clean a solution before moving and copying project files. To do this, select **Clean** in the **Build** menu.

Copy an Existing Intel® Fortran Project to Another Disk or System

1. Copy all project files to the new location. You do not need to copy the subdirectories created for each configuration. Keep the directory hierarchy intact by copying the entire project tree to the new computer. For example, if a project resides in the folder `\MyProjects\Projapp` on one computer, you can copy the contents of that directory, and all subdirectories, to the `\MyProjects\Projapp` directory on another computer.
2. Delete the following files from the main directory at the new location. These files are disk- and computer-specific and should not be retained:
   - `*.SUO` files
   - `*.NCB` files (if present)
3. If you copied the subdirectories associated with each configuration (for example, **Debug** and **Release**), delete the contents of subdirectories at the new location. The files contained in these subdirectories are disk- and computer-specific files and should not be retained. For example, Intel® Fortran module (`.MOD`) files contained in these subdirectories should be recreated by the compiler, especially if a newer version of Intel® Fortran has been installed.

   NOTE The internal structure of module files can change between Intel® Fortran releases.

   If you copied the project files to the same system or a system running the same platform and major Intel® Fortran version, do the following steps to remove most or all of the files in the configuration subdirectory:

   1. Open the appropriate solution. In the **File** menu, either select **Open Solution** or select **Recent Solutions**. If you use **Open Solution**, select the appropriate `.SLN` file.
   2. Select **Set Active Configuration** in the **Build** menu and select a configuration.
   3. Select **Clean** in the **Build** menu.
   4. Repeat the previous two steps for other configurations whose subdirectories have been copied.
4. If possible, after copying a project, verify that you can open the project at its new location using the same Fortran version that it was created in. This ensures that the project has been moved successfully and minimizes the chance of conversion problems. If you open the project with a later version of Fortran, the project will be converted and you will not be able to convert the project back. For this reason, making an archive copy of the project files before you start is recommended.
5. View the existing configurations. To view the existing configurations associated with the project, open the solution and view available configurations using the drop-down box at the top of the screen.
6. Check and reset project options.

   Because not all settings are transportable across different disks and systems, you should verify your project settings on the new platform. To verify your project settings:

   a. From the **Project** menu, choose **Properties**. The **Project Property Pages** dialog box appears.
   b. Configure settings as desired. Pay special attention to the following items:
      - **General:** Review the directories for intermediate and output files. If you moved the project to a different system, be aware that any absolute directory paths (such as `C:\TEMP` or `\Myproj\TEMP`) will most likely need to be changed. Instead, use relative path directory names (without a leading back slash), such as `Debug`
      - **Custom Build Step:** Review for any custom commands that might change between platforms.
      - **Pre-build**, **Pre-link**, and **Post-build Steps** in **Build Events:** Review for any custom commands that may have changed.
7. Check your source code for directory paths referenced in `INCLUDE` or similar statements. Microsoft Visual Studio* provides a multi-file search capability called **Find in Files**, available from the **Edit menu**.

About Fortran Project Types

Understanding Project Types

When you create a project in Visual Studio*, you must choose a *project type*. You need to create a project for each binary executable file to be created. For example, the main Fortran program and a Fortran dynamic-link library (DLL) would each reside in the same solution as separate projects.

The project type specifies what to generate and determines some of the options that the visual development environment sets by default for the project. It determines, for instance, the options that the compiler uses to compile the source files, the static libraries that the linker uses to build the project, and the default locations for output files.

When you select a project type, an Application wizard (AppWizard) is launched, which guides you through project set-up. The AppWizard supplies default settings for both the **Release** and **Debug** Configurations of the project. For more information about configurations, see Understanding Solutions Projects and Configurations and Selecting a Configuration.

The following table lists the available Intel® Fortran Compiler project types. The first four projects listed are main project types, requiring main programs. The last two are library projects, without main programs.

Project Type	Key Features
Using Fortran Console Application Projects (`.EXE`)	Single window main projects without graphics (resembles character-cell applications). Requires no special programming expertise.
Using Fortran Standard Graphics Application Projects (`.EXE`)	Single window main projects with graphics. The programming complexity is simple to moderate, depending on the graphics and user interaction used.
Using Fortran QuickWin Application Projects (`.EXE`)	Multiple window main projects with graphics. The programming complexity is simple to moderate, depending on the graphics and user interaction used.
Using Fortran Windowing Application Projects (`.EXE`)	Multiple window main projects with full graphical interface and access to all Windows* API routines. Requires advanced programming expertise and knowledge of the Calling Windows API Routines.
Using Fortran Static Library Projects (`.LIB`)	Library routines to link into `.EXE` files.
Using Fortran Dynamic-Link Library Projects (`.DLL`)	Library routines to associate during execution.
Using the Fortran COM Server (`.DLL`)	Fortran in-process COM server

If you need to use the command line to build your project, you can:

- Use the command line compiler options to specify the project type (see Specifying Project Types with ifort Command Options).
- Create the application from the command line (see Invoking the Intel® Fortran Compiler).

Selecting a Configuration

Additional Documentation: Creating Fortran Applications that Use Windows* OS Features

Specifying Project Types with ifort Command Options

This section provides the `ifort` command-line options that correspond to Visual Studio* project types.

Creating Main Project Types

The first four projects described below are main project types, requiring main programs. You can create any of the following project types with the `ifort` command:

- To create Console Application Projects, you do not need to specify any options. (If you link separately, specify the `link` option `/subsystem:console`.) This is the default project type created.
- To create Standard Graphics Application Projects, specify the `libs` option with keyword `qwins` (also sets certain linker options).
- To create QuickWin Application Projects, specify the `libs` option with keyword `qwin` (also sets certain linker options).
- To create Windowing Application Projects, specify the `winapp` option (also sets certain linker options).

Creating Library Project Types

The following project types are library projects, without main programs. You can create them with the `ifort` command:

- To create Dynamic-Link Library Projects, specify the `dll` option (which sets the `libs` option with keyword `dll`).
- To create Static Library Projects:
  - If your application will not call any QuickWin or Standard Graphics routines, specify the `libs` option with keyword `static` and `c` options to create the object files.
  - If your application will call QuickWin routines, specify the `libs` option with keyword `qwin` and `c` options to create the object files.
  - If your application will call Standard Graphics routines, specify the `libs` option with keyword `qwins` and `c` options to create the object files.
  - Use the `LIB` command to create the library.

Using Fortran Standard Graphics Application Projects
Using Fortran QuickWin Application Projects
Using Fortran Windowing Application Projects
Using Fortran Dynamic-Link Library Projects
Using Fortran Static Library Projects

Using Fortran Console Application Projects

A Fortran Console application (`.EXE`) is a character-based Intel® Fortran program that does not require screen graphics output.

Fortran Console projects operate in a single window and let you interact with your program through normal read and write commands. Console applications are better suited to problems that require pure numerical processing rather than graphical output or a graphical user interface. This type of application is also more transportable to other platforms than the other types of application.

Fortran Console applications can be faster than Fortran Standard Graphics or Fortran QuickWin graphics applications, because of the resources required to display graphical output (see Using the Console).

Any graphics routine that your program calls will produce no output, but will return error codes. A program will not automatically exit if such an error occurs, so your code should be written to handle this condition.

With a Fortran Console project, you cannot use the QuickWin functions. However, you can use single- or multi-threaded static libraries, DLLs, and dialog boxes.

As with all Windows* command consoles, you can toggle between console viewing modes by pressing ALT and ENTER.

To create a console application from the IDE:

1. Select the **Console Application** project type.
2. Select from two templates: **Empty project** or **Main program code**, which includes sample code.

See Also

Using the Console

Using Fortran Standard Graphics Application Projects

A Fortran standard graphics application (`.EXE`) is an Intel® Fortran QuickWin program with graphics that runs in a single QuickWin window. A standard graphics (QuickWin single window, sometimes called single document) application looks similar to an MS-DOS* program when manipulating the graphics hardware directly, without Windows*.

A Fortran standard graphics application allows graphics output (such as drawing lines and basic shapes) and other screen functions, such as clearing the screen. Standard Graphics is a subset of QuickWin. You can use all of the QuickWin graphics functions in these projects. You can use dialog boxes with these and all other project types.

You can select displayed text either as a bitmap or as text. Windows* provides APIs for loading and unloading bitmap files. Standard graphics applications should be written as multithreaded applications.

Fortran standard graphics (QuickWin single window) applications are normally presented in full-screen mode. The single window can be either full-screen or have window borders and controls available. You can change between these two modes by using ALT and ENTER.

If the resolution selected matches the screen size, the application covers the entire screen; otherwise, scroll bars are present to resize the window. You cannot open additional windows in a standard graphics application. Standard graphics applications have neither a menu bar at the top of the window, nor a status bar at the bottom.

Fortran standard graphics applications are appropriate for problems that:

- Require numerical processing and some graphics.
- Do not require a sophisticated user interface.

To create a standard graphics application using the Visual Studio* IDE:

1. Select the **QuickWin Application** project type.
2. Select the **Standard Graphics Application** template.

When you select the Fortran standard graphics project type, the integrated development environment includes the QuickWin library automatically, which lets you use the graphics functions. When building from the command line, you must specify the `libs` option with keyword `qwins`. You cannot use the run-time functions meant for multiple-window projects if you are building a standard graphics project. You cannot make a Standard Graphics application a DLL.

See Also

Additional Documentation: Creating Fortran Applications that Use Windows* Features

Using Fortran QuickWin Application Projects

Fortran QuickWin graphics applications (`.EXE`) are multi-threaded and are more versatile than standard graphics (QuickWin single window) applications because you can open multiple windows while your project is executing. This multiple window capability is also referred to as multiple-document interface or MDI. Multiple windows can be used in a variety of ways. For example, you might want to generate several graphic plots and be able to switch between them while also having a window for controlling the execution of your program. These windows can be full screen or reduced in size and can be placed in various parts of the screen.

QuickWin library routines let you build applications with a simplified version of the Windows* interface using Intel® Fortran. The QuickWin library provides a rich set of Windows* features, but it does not include the complete Windows* Applications Programming Interface (API). If you need additional capabilities, you must set up a Windows* application to call the Windows* API directly rather than using QuickWin to build your program.

Applications that use a multiple-document interface (MDI) have a menu bar at the top of the window and a status bar at the bottom. The QuickWin library provides a default set of menus and menu items that you can customize with the QuickWin APIs. An application that uses MDI creates many "child" windows within an outer application window. The user area in an MDI application is a child window that appears in the space between the menu bar and status bar of the application window. Your application can have more than one child window open at a time.

Fortran QuickWin applications can use the `IFLOGM` module to access functions to control dialog boxes. These functions allow you to display, initialize, and communicate with special dialog boxes in your application. They are a subset of Windows* API functions, which Windows* applications can call directly.

To create a QuickWin application in Visual Studio*:

1. Select the **QuickWin Application** project type.
2. Select the **QuickWin Application** template in the right pane.

When you select the Fortran QuickWin project type, the IDE includes the QuickWin library automatically, which lets you use the graphics functions.

When building from the command line, you must specify the `libs` compiler option with keyword `qwin` to indicate a QuickWin application.

A QuickWin application covers the entire screen if the resolution selected matches the screen size; otherwise, the window will contain scroll bars.

You cannot make a Fortran QuickWin application a DLL.

See Also

Additional Documentation: Creating Fortran Applications that Use Windows* Features

Using Fortran Windowing Application Projects

Fortran Windowing applications (`.EXE`) are main programs that you create when you choose the Fortran Windowing Application project type. This type of project lets you call the Windows* APIs directly from Intel® Fortran. This provides full access to the Windows* APIs, giving you a larger (and different) set of functions to work with than QuickWin.

Although you can call some of the Windows* APIs from the other project types, Fortran Windowing applications allow you to use the full set of API routines and use certain system features not available for the other project types.

The `IFWIN` module contains interfaces to the most common Windows APIs. If you include the `USE IFWIN` statement in your program, the most common Windows* API Routines are available to you. The `IFWIN` module gives you access to a full range of routines including window management, graphic device interface, system services, multimedia, and remote procedure calls.

Window management routines give your application the means to create and manage a user interface. You can create windows to display output or prompt for input. Graphics Device Interface (GDI) functions provide ways for you to generate graphical output for displays, printers, and other devices. Windows* system functions allow you to manage and monitor resources such as memory, access to files, directories, and I/O devices. System service functions provide features that your application can use to handle special conditions such as errors, event logging, and exception handling.

Using multimedia functions, your application can create documents and presentations that incorporate music, sound effects, and video clips as well as text and graphics. Multimedia functions provide services for audio, video, file I/O, media control, joystick, and timers.

Remote Procedure Calls (RPC) gives you the means to carry out distributed computing, letting applications tap the resources of computers on a network. A distributed application runs as a process in one address space and makes procedure calls that execute in an address space on another computer. You can create distributed applications using RPC, each consisting of a client that presents information to the user and a server that stores, retrieves, and manipulates data as well as handling computing tasks. Shared databases and remote file servers are examples of distributed applications.

Using Fortran Static Library Projects

Fortran static libraries (`.LIB`) are blocks of code compiled and kept separate from the main part of your program. The Fortran static library is one of the Fortran project types.

To create a static library from the integrated development environment (IDE), select the **Static Library** project type. To create a static library from the command line, use the `c` option to suppress linking and use the `LIB` command.

> **NOTE**
> When compiling a static library from the command line, include the `c` option to suppress linking. Without this option, the compiler generates an error because the library does not contain a main program.

When you create a static library, you are asked to specify whether you want to prevent the insertion of link directives for default libraries. By default, this checkbox is selected, which means insertion of link directives is prevented. Select this option if you plan to use this static library with other Fortran projects. The option prevents the static library from specifying a version of the Fortran run-time library. When the static library is linked with another Fortran project, the Fortran run-time library choice in the other Fortran project is used for the static library as well.

You may decide against selecting this option if you plan to use this static library with C/C++ projects. If you do select it, you need to explicitly name the Fortran run-time library to use in the Linker **Additional Dependencies** property. You can change your selection after creating the project using the **Fortran Disable Default Library Search Rules** property.

A static library is a collection of source and object code defined in the **Solution Explorer** window. The source code is compiled when you build the project. The object code is assembled into a `.LIB` file without going through a linking process. The name of the project is used as the name of the library file by default. Static libraries offer important advantages in organizing large programs and in sharing routines between several programs. These libraries contain only subprograms, not main programs. A static library file has a `.LIB` extension and contains object code.

When you associate a static library with a program, any necessary routines are linked from the library into your executable program when it is built. Static libraries are usually kept in their own directories. If you use a static library, only those routines actually needed by the program are incorporated into the executable image (`.EXE`). This means that your executable image will be smaller than if you included all the routines in the library in your executable image. The Linker determines which routines to include.

Because applications built with a static library all contain the same version of the routines in the library, you can use static libraries to help keep applications current. When you revise the routines in a static library, you can easily update all the applications that use it by relinking the applications.

If you have a library of substantial size, you should maintain it in a dedicated directory. Projects using the library access it during linking.

When you link a project that uses the library, selected object code from the library is linked into that project's executable code to satisfy calls to external procedures. Unnecessary object files are not included.

To debug a static library, you must use a main program that calls the library routines. Both the main program and the static library should have been compiled using the debug option. After compiling and linking is completed, open the **Debug** menu and choose **Go** to reach breakpoints, or use the step controls on the **Debug** toolbar.

Using Static Libraries

To add static libraries to a main project in the IDE, use the **Add Existing Item...** option in the **Project** menu. You can enter the path and library name with a `.LIB` extension in the dialog box that appears. If you are using a makefile, you must add the library by editing the makefile for the main project. If you are building your project from the command line, add the library name with a `.LIB` extension and include the path specification if necessary.

Using Fortran Dynamic-Link Library Projects

A dynamic-link library (`.DLL`) is a source-code library that is compiled and linked to a unit independently of the applications that use it. A DLL shares its code and data address space with a calling application. A DLL contains only subprograms, not main programs.

A DLL offers the organizational advantages of a static library, but with the advantage of a smaller executable file at the expense of a slightly more complex interface. Object code from a DLL is not included in your program's executable file, but is associated as needed in a dynamic manner while the program is executing. More than one program can access a DLL at a time.

When routines in a DLL are called, the routines are loaded into memory at run-time, as they are needed. This is most useful when several applications use a common group of routines. By storing these common routines in a DLL, you reduce the size of each application that calls the DLL. In addition, you can update the routines in the DLL without having to rebuild any of the applications that call the DLL.

With Intel® Fortran, you can use DLLs in two ways:

1. You can build a DLL with your own routines. In Visual Studio*, select **Dynamic-link Library** as your project type. From the command line, use the `DLL` option with the `ifort` command.
2. You can build applications with the run-time library stored in a separate DLL instead of in the main application file. In the integrated development environment, open a solution and do the following:

   - From the **Project** menu, select **Properties** to display the project properties dialog box.
   - Click the **Fortran** folder.
   - Select the **Libraries** category.
   - In the **Runtime Library** option, select an option ending with "DLL."

   From the command line, use the `libs` compiler option with keyword `dll` to build applications with the run-time library stored in a separate DLL.

Using the Console

On Windows* OS, a console window allows input and output of characters (not graphics).

For example, data written (explicitly or implicitly) by Fortran `WRITE` (or other) statements to Fortran logical unit 6 display characters on a console window. Similarly, data read by Fortran `READ` (or other) statements to unit 5 accept keyboard character input.

The console consists of two components:

- The actual console window that shows the characters on the screen.
- The console buffer that contains the characters to be displayed.

If the console screen buffer is larger than the console window, scroll bars are automatically provided. The size of the console screen buffer must be larger (or equal to) the size of the console window. If the buffer is smaller than the size of the console window, an error occurs. For applications that need to display more than a few hundred lines of text, the ability to scroll quickly through the text is important.

Fortran Console applications automatically provide a console. Fortran QuickWin (and Fortran Standard Graphics) applications do not provide a console, but display output and accept input from Fortran statements by using the program window.

The following Fortran Project Types provide an application console window:

Project Type	Description of Console Provided
Fortran Console	Provides a console window intended to be used for character-cell applications that use text only. When running a Fortran Console application from the command prompt, the existing console environment is used. When you run the application from Windows* or Developer Studio* (by selecting **Start Without Debugging** in the **Debug** menu), a new console environment is created. Basic console use is described in Code Samples of Console Use.
Fortran QuickWin or Fortran Standard Graphics	Does not provide a console, but output to unit 6 and input to unit 5 are directed to the application program window, which can handle both text and graphics. Because the program window must handle both text and graphics, it is not as efficient as the console for just text-only use. A Fortran QuickWin or Fortran Standard Graphics program window (or child window) provides a console-like window. See Console Use for Fortran QuickWin and Fortran Standard Graphics Applications.
Fortran Windows	Does not provide a console window, but the user can create a console by using Windows* API routines. See Console Use for Fortran Windows* Applications and Fortran DLL Applications.
Fortran DLL	Does not provide a console window, but the user can create a console by using Win32 routines. See Console Use for Fortran Windows* Applications and Fortran DLL Applications.
Fortran Static Library	Depends upon the project type of the main application that references the object code in the library (see above project types).

In addition to the Windows* API routines mentioned below, there are other routines related to console use described in the Microsoft Platform SDK* documentation.

Console Use for Fortran QuickWin and Fortran Standard Graphics Applications

For a Fortran QuickWin or Fortran Standard Graphics application, because the default program window handles both graphics and text, the use of a QuickWin window may not be very efficient:

- QuickWin windows use lots of memory and therefore have size limitations.
- They can be slow to scroll.

Although you can access the console window using `WRITE` and `READ` (or other) statements, applications that require display of substantial lines of text, consider creating a DLL that creates a separate console window for efficiency. The DLL application needs to call Windows* API routines to allocate the console, display text, accept keyed input, and free the console resources.

Basic use of a console is described in Code Samples of Console Use.

Console Use for Fortran Windows Applications and Fortran DLL Applications

With a Fortran Windows* or Fortran DLL application, attempting to write to the console using `WRITE` and `READ` (or other) statements before a console is created results in a run-time error (such as error performing `WRITE`).

A console created by a Fortran DLL is distinct from any application console window associated with the main application. A Fortran DLL application has neither a console nor an application window created for it, so it must create (allocate) its own console using Windows* API routines. When used with a Fortran QuickWin or Fortran Standard Graphics application main program, the Fortran DLL can provide its main application with a very efficient console window for text-only use.

Like a Fortran DLL application, a Fortran Windows application has neither a console nor an application window created for it, so it must create its own console using Windows* API routines. After allocating a console in a Fortran DLL, the handle identifier returned by the `GetStdHandle` Windows* API routine refers to the actual console the DLL creates.

When the Fortran Windows application does create a console window, it is very efficient for text-only use. The handle identifier returned by the `GetStdHandle` Calling Windows* API Routines refers to the actual console the Fortran Windows application creates.

For information about creating a console, see Allocating and Deallocating a Console below.

Code Samples for Console Use

The following sections shows sample code for using a console:

- Allocating and Deallocating a Console for Fortran Windows* and DLL Applications.
- Extending Size of the Console Window and Console Buffer for console use in any project type.
- Writing and Reading Characters at a Cursor Position for console use in any project type.

Allocating and Deallocating a Console

To create a console, you use the `AllocConsole` routine. When you are done with the console, free its resources with a `FreeConsole` routine. For example, the following code allocates the console, enlarges the buffer size, writes to the screen, waits for any key to be pressed, and deallocates the console:

```
! The following USE statement provides Fortran interfaces to Windows routines
    USE IFWIN
! Begin data declarations
    integer lines,length
    logical status
    integer fhandle
    Type(T_COORD) wpos
! Set buffer size variables
    length = 80
     lines  = 90
! Begin executable code
!   Allocate a console
    status = AllocConsole() ! get a console window of the currently set size
    handle = GetStdHandle(STD_OUTPUT_HANDLE)
    wpos.x = length   ! must be >= currently set console window line length
    wpos.y = lines    ! must be >= currently set console window number of lines
    ! Set a console buffer bigger than the console window. This provides
    ! scroll bars on the console window to scroll through the console buffer
    status = SetConsoleScreenBufferSize(fhandle, wpos)
     ! Write to the screen as needed. Add a READ to pause before deallocation
     write (*,*) "This is the console output! It might display instructions or data "
```

```
     write (*,*) " "
     write (*,*) "Press any key when done viewing "
     read (*,*)
!    Deallocate the console to free its resources.
     status = FreeConsole()
```

Calling Windows* API routines is described in Calling Windows* API Routines.

If you are using a DLL, your DLL code will need to create subprograms and export their symbols to the main program.

Basic use of a console is described in Extending Size of the Console Window and Console Buffer and Writing and Reading Characters at a Cursor Position.

Extending the Size of the Console Window and Console Buffer

When you execute a Fortran Console application, the console is already allocated. You can specify the size of the console window, size of the console buffer, and the location of the cursor. If needed, you can extend the size of the console buffer and console window by using the following Windows* API routines:

1. You first need to obtain the handle of the console window using the `GetStdHandle` routine. For example:

```
! USE statements to include routine interfaces
use ifqwin
use ifport
use ifcore
use ifwin
! Data declarations
integer fhandle
logical lstat
! Executable code
fhandle = GetStdHandle(STD_OUTPUT_HANDLE)
! ...
```

2. If needed, you can obtain the size of the:
   - Console window by using the `GetConsoleWindowInfo` routine.
   - Console buffer by using the `GetConsoleScreenBufferInfo` routine.

   For example:

```
! USE statements to include routine interfaces
use ifqwin
use ifport
use ifcore
use ifwin
! Data declarations
integer fhandle
logical lstat
Type(T_CONSOLE_SCREEN_BUFFER_INFO) conbuf
type (T_COORD)         dwSize
type (T_SMALL_RECT)    srWindow
fhandle = GetStdHandle(STD_OUTPUT_HANDLE)
! Executable code to get console buffer size
lstat = GetConsoleScreenBufferInfo(fhandle, conbuf)
write (*,*) " "
write (*,*) "Window coordinates= ", conbuf.srWindow
write (*,*) "Buffer size= ", conbuf.dwSize
! ...
```

3. To set the size of the console window and buffer, use the `SetConsoleWindowInfo` and `SetConsoleScreenBufferSize` routines with the **fhandle** value returned previously:

```
!  USE statements to include routine interfaces
use ifqwin
use ifport
use ifcore
use ifwin
! Data declarations
integer nlines, ncols
logical lstat
Type(T_COORD) wpos
Type(T_SMALL_RECT) sr
Type(T_CONSOLE_SCREEN_BUFFER_INFO) cinfo
! Executable code to set console window size
sr.top    =   0
sr.left   =   0
sr.bottom =   40 ! <= console buffer height
 -1
sr.right  =   60 ! <=
 console buffer width  -1
lstat = SetConsoleWindowInfo(fhandle, .TRUE., sr)
! Executable code to set console buffer size
nlines = 100
ncols  =  80
wpos.x = ncols  ! columns >= console window width
wpos.y = nlines ! lines   >= console window height
lstat = SetConsoleScreenBufferSize(fhandle, wpos)
! ...
```

Writing and Reading Characters at a Cursor Position

You can position the cursor as needed using the `SetConsoleCursorPosition` routine before you write characters to the screen:

```
! Use previous data declarations
! Position and write two lines
  wpos.x = 5 ! 6 characters from left
  wpos.y = 5 ! 6 lines down
  lstat = SetConsoleCursorPosition(fhandle, wpos)
  write(*,*) 'Six across Six down'
! ...
```

You read from the screen at an appropriate place, but usually you should set the cursor relative to the starting screen location:

```
 ! Use previous and the following data declaration
  CHARACTER(Len=50) charin
! Go back to beginning position of screen
  wpos.x = 0 ! 0 characters from left
  wpos.y = 0 ! 0 lines down
  lstat = SetConsoleCursorPosition(fhandle, wpos)
! Position character input at start of line 11
  wpos.x = 0 ! first character from left
  wpos.y = 10 ! 11 lines down
  lstat = SetConsoleCursorPosition(fhandle, wpos)
  read(*,*) charin
! ...
```

For console I/O, you can use Windows* OS routines `WriteConsoleLine` and `ReadConsoleLine` instead of Fortran `WRITE` and `READ` statements.

Additional Documentation: Creating Fortran Applications that Use Windows* Features

A separate document is available that details creating Intel® Fortran applications that use Windows* features.

You can find *Using Intel® Visual Fortran to Create and Build Windows*-Based Applications* on the Intel® Software Documentation Library website at http://software.intel.com/en-us/intel-software-technical-documentation. To get to this document, filter the page for the product suite or the single product.

The document covers the following:

- **Creating Fortran Windowing Applications:** Windows-based applications use the familiar Windows* interface, complete with tool bars, pull-down menus, dialog boxes, and other features. You can include data entry and mouse control in your application and allow for interaction with programs written in other languages or commercial programs such as Microsoft Excel*.
- **Creating and Using Fortran DLLs:** A dynamic-link library (DLL) contains one or more subprogram procedures (functions or subroutines) that are compiled, linked, and stored separately from the applications using them. Because the functions or subroutines are separate from the applications using them, they can be shared or replaced easily.
- **Using QuickWin:** The Intel® Fortran QuickWin run-time library helps you turn graphics programs into simple Windows* applications. Though the full capability of Windows* is not available through QuickWin, QuickWin is simpler to learn and to use. QuickWin applications support pixel-based graphics, real-coordinate graphics, text windows, character fonts, user-defined menus, mouse events, and editing (select/copy/paste) of text, graphics, or both.
- **Using Dialog Boxes for Application Controls:** Dialog boxes are a user-friendly way to solicit application control. As your application executes, you can make a dialog box appear on the screen and the user can click on a dialog box control to enter data or choose what happens next. Using the dialog routines provided with Intel® Fortran, you can add dialog boxes to your application. These routines define dialog boxes and their controls (scroll bars, buttons, and so on), and call your subroutines to respond to user selections.

Optimization Reports: Enabling in Microsoft Visual Studio*

Optimization reports can help you address vectorization and optimization issues.

When you build a solution or project, the compiler generates optimization diagnostics. You can view the optimization reports in the following windows:

- The **Compiler Optimization Report** window, either grouped by loops or in a flat format.
- The **Compiler Inline Report** window.

- The optimization annotations, which are integrated within the source editor.

To enable viewing for the optimization reports:

1. In your project's property pages, select **Configuration Properties** > **Fortran** > **Diagnostics**.
2. Set a non-default value for any of the following options:
   - **Optimization Diagnostics Level**
   - **Optimization Diagnostics Phase**
   - **Optimization Diagnostics Routine**
3. The Interprocedural Optimization (IPO) is turned off by default. To view the IPO diagnostics, set the property **Fortran** > **Optimization** > **Interprocedural Optimization** to **Single-file** or **Multi-file**.
4. Build your project to generate an optimization report.

When the compiler generates optimization diagnostics, the **Compiler Optimization Report** and the **Compiler Inline Report** windows open, and the optimization report annotations appear in the source editor.

> **NOTE** You can specify how you want the optimization reporting to appear with the **Optimization Reports** dialog box. Access this dialog box by selecting **Tools** > **Options** > **Intel Compilers and Tools** > **Optimization Reports**.

See Also

Options: Optimization Reports dialog box

Optimization Reports: Viewing

When the compiler generates optimization diagnostics, the **Compiler Optimization Report** and the **Compiler Inline Report** windows open, and optimization report annotations appear in the editor.

Compiler Optimization Report window

The **Compiler Optimization Report** window displays diagnostics for the following phases of the optimization report:

- PGO
- LOOP
- PAR
- VEC
- Offload (Linux* only)
- OpenMP
- CG

Information appears in this window grouped by loops, or in a flat format. To switch the presentation format, click the gear button on the toolbar of the window, and uncheck **Group by loops**.

In addition to sorting information by clicking column headers and resizing columns, you can use the windows described in the following table:

Do This	To Do This
Double-click a diagnostic.	Jump to the corresponding position in the editor.
Click a link in the **Inlined into** column.	Jump to the call site of the function where the loop is inlined.
Expand or collapse a diagnostic in **Group by loops** view.	View detailed information for the diagnostic.
Click on a column header.	Sort the information according to that column.

Do This	To Do This
Click the filter button.	Select a scope by which to filter the diagnostics that appear in the window. The title bar of the **Compiler Optimization Report** window shows the applied filter. Labels on optimization phase filter buttons show how many diagnostics of each phase are in the current scope.
Click a **Compiler Optimization Report** window toolbar button corresponding to an optimization report phase.	Turn filtering diagnostics on or off for an optimization phase. Labels on optimization phase filter buttons show the total number of diagnostics for each phase. By default all phases turned on.
Enter text in the search box in the **Compiler Optimization Report** window toolbar.	Filter diagnostics using the text pattern. Diagnostics are filtered when you stop typing. Pressing Enter saves this pattern in the search history. To disable filtering, clear the search box. To use a pattern from the search history, click on the down arrow next to the search box.

Compiler Inline Report window

The **Compiler Inline Report** window displays diagnostics for the IPO phase of the optimization report.

Information appears in this window in a tree. Each entry in the tree has corresponding information in the right-hand pane under the **Properties** tab and the **Inlining options** tab.

You can use the window as described in the following table:

Do This	To Do This
Double-click a diagnostic in the tree, or click on the source position link under the **Properties** tab.	Jump to the corresponding position in the editor.
Click **Just My Code**.	Only display functions from your code, filter all records from files that don't belong to the current solution file tree.
Right-click on a function body in the editor and select **Intel Compiler** > **Show Inline report for *function name***.	View detailed information for the specified function.
Right-click on a function body in the editor and select **Intel Compiler** > **Show where *function name* in inlined**.	Show where the specified function is inlined.
Enter text in the search box in the **Compiler Inline Report** window toolbar.	Filter diagnostics using the text pattern. Diagnostics are filtered when you stop typing. Pressing Enter saves this pattern in the search history. To disable filtering, clear the search box.

Do This	To Do This
	To use a pattern from the search history, click on the down arrow next to the search box.

Viewing Optimization Notes in the Editor

Viewing optimization notes in the editor provides context for the diagnostics that the compiler generates.

1. In Caller Site
2. In Callee Site
3. In Caller and Callee Site

You can use optimization notes as described in the following table:

Do This	To Do This

Right-click an optimization note	• Expand or collapse the current optimization note, or all of them.
	• Open the **Optimization Reports** dialog box to adjust settings for optimization report viewing. You can view optimization notes in one of the following locations:
	  • **Caller Site**
	  • **Callee Site**
	  • **Caller Site and Callee Site**

Double-click an optimization note heading.	Expand or collapse the current optimization note.
Double-click a diagnostic detail.	Jump to the corresponding position in the editor.
Click a hyperlink in the optimization note.	Show where the specified function is inlined.
Click the help **(?)** icon.	Get detailed help for the selected diagnostic. The default browser opens and, if you are connected to the internet, displays the help topic for this diagnostic.
Hover the mouse over a collapsed optimization note.	View a detailed tooltip about that optimization note.

Dialog Box Help

Options: General dialog box

To access the **General** page, click **Tools** > **Options** and then select **Intel Compilers and Tools** > **Visual Fortran** > **General**. Use this page to specify Fortran File Extensions and Build Options.

Build Options

Continue on Errors: Check this box to allow compilation to continue regardless of an error in the current file. The compiler will begin compiling the next file. (To set the maximum number of errors to encounter before compilation stops, choose **Configuration Properties** > **Fortran** > **Diagnostics** > **Error Limit**).

Generate Build Logs: Check this box to generate build logs.

Show Environment in Log: Check this box to show environment variable settings in the log file.

Fortran File Extensions

You can specify additional Fortran free format and fixed format file extensions to be recognized as valid file extensions within the IDE. The IDE treats these additional extensions as compilable Fortran source files. You can also remove or modify existing extensions that appear in the list.

When you add a new extension, the IDE checks the registry to determine whether the extension is already associated with a language, tool, or file format. If there is such an association, a message informs you of this and you will not be allowed to add the extension.

Headers: Specify one or more file extensions for header files, each beginning with a period and separated by semi-colons.

Sources: Specify one or more file extensions for source files, each beginning with a period and separated by semi-colons.

Click **OK** to save your changes.

Options: Compilers dialog box

To access the **Compilers** page:

1. Open **Tools** > **Options**
2. In the left pane, select **Intel Compilers and Tools** > **Visual Fortran** > **Compilers**.

See Also

Selecting the Compiler Version
Specifying Path, Library, and Include Directories

Options: Advanced dialog box

To access the **Advanced** page, expand the **Tools** > **Options** > **Text Editor** > **Fortran** nodes and select **Advanced**. Here you can specify advanced options for text editing.

Browsing/Navigation section

Collect Object Browser information: Choose this option to enable the display of procedures in your project in a hierarchical tree. Once enabled, you can use **View** > **Object Browser** to display your procedures.

Disable Database: Choose this option to disable creation of the code browsing database. This may help increase performance on slow machines. When you disable the database, all features that rely on code browsing information do not work.

Enable Database Saving/Loading: Choose this option to save collected data to a file on disk so that all source browsing features are available immediately when you open the project. When this option is disabled, the code browsing database is generated via background source parsing, so many features that rely on code browsing information do not work until this process completes. Saving and loading the database requires some additional time when saving and loading the project.

Enable Find all References: Choose this option to enable display of the location(s) in your code where a symbol is referenced. When this option is enabled, you can use the right-click context menu **Find All References** option to display a list of references to the selected symbol. Double-click on a reference to find that reference.

Enable Go To Definition: Choose this option to enable quick navigation to an object definition. When this option is enabled, you can use the right-click context menu **Go to Definition** option to locate where the selected object was declared, opening the associated source file if required. (If you have also enabled **Scan system includes**, any objects declared in system modules such as IFWINTY cause the associated source for that module to be opened.)

Scan system includes: Choose this option to scan system include files. This option is used with one or more of the following options: **Collect Object Browser Information**, **Enable Find All References**, **Enable Go To Definition**.

Intrinsics section

Enable Intrinsic Parameter Info: Choose this option to enable the display of intrinsic function and subroutine parameter information. When this option is enabled, you can type a name of an intrinsic procedure, followed by an open parenthesis, and information about the procedure and its arguments appears.

Enable Intrinsic Quick Info: Choose this option to enable the display of additional information when the mouse pointer is moved over an intrinsic function or subroutine name.

Miscellaneous section

Enumerate Comment Tasks: Choose this option to enable the display of a list of tasks consisting of source files containing comments. Comments take the form of the ! character, followed by a token such as TO DO. Valid tokens are those listed in **Tools** > **Options** > **Environment** > **Task List**. When this option is enabled, you can select **Comments** from the task list using **View** > **Other Windows Task List**. Double-click on a comment in the list to jump to its location.

Highlight Matching Tokens: Choose this option to allow identifier highlighting and block delimiter matching. When enabled, this option highlights all references to the identifier under the cursor.

Outlining Section

Enable Outlining: Choose this option to allow the collapsing of whole program units. When this option is enabled, you can click the minus (**-**) or plus (**+**) symbols for `PROGRAM`, `SUBROUTINE`, `FUNCTION`, `MODULE`, and `BLOCK DATA` statements.

Outline Statement Blocks: Choose this option to allow collapsing of block constructs such as `IF` and `DO`. You must also choose **Enable Outlining**.

Configure Analysis dialog box

Use the **Configure Analysis** dialog box to specify settings for Guided Auto Parallelism (GAP) analysis and run the analysis.

To access this dialog box, click **Tools** > **Intel Compiler** > **Guided Auto Parallelism** > **Run Analysis...**

Configure Analysis Options

Scope: Specify the desired scope.

Level of Analysis: Specify the desired level of analysis. Choose **Simple**, **Moderate**, **Maximum**, or **Extreme**.

Suppress Compiler Warnings: Check this box to suppress compiler warnings. This adds the option `W0` to the compiler command line.

Suppress remark IDs: Specify one or more remark IDs to suppress. Use a comma to separate IDs.

Send remarks to a file: Check this box to send GAP remarks to a specified text file.

Remarks file: Specify the filename where GAP remarks will be sent.

Save these settings as the default (in Tools -> Options for Guided Auto Parallelism): Check this box to save the specified settings as the default settings.

Show all GAP configuration and informational dialogs: Check this box to display this dialog box next time.

When you are done specifying settings, click **Run Analysis**.

See Also

Options: Guided Auto Parallelism dialog box

Options: Guided Auto Parallelism dialog box

Use the **Guided Auto Parallelism** page to specify settings for Guided Auto Parallelization (GAP) analysis.

To access the **Guided Auto Parallelism** page click **Tools** > **Options** and then select: **Intel Compilers and Tools** > **Visual Fortran** > **Guided Auto Parallelism**.

> **NOTE** These settings are used when running analysis using **Tools** > **Intel Compiler** > **Guided Auto Parallelism** > **Run Analysis on project...**

Guided Auto Parallelism Options

Level of Analysis: Specify the desired level of analysis. Choose **Simple**, **Moderate**, **Maximum**, or **Extreme**.

Suppress compiler warnings: Check this box to suppress compiler warnings. Selection adds option `W0` to the compiler command line.

Suppress Remark IDs: Specify one or more remark IDs to suppress. Use a comma to separate IDs.

Send remarks to a file: Check this box to send GAP remarks to a specified text file.

Remarks file: Specify the filename to send GAP remarks to.

Show all GAP configuration and informational dialogs: Check this box to display additional dialog boxes when you run an analysis.

Reset: Click this button to restore the previously selected settings.

Using Guided Auto Parallelism

Profile Guided Optimization dialog box

This topic has information on the following dialog boxes:

- **Profile Guided Optimization (PGO)** dialog box
- **Application Invocations** dialog box
- **Edit Command** dialog box
- **Command** dialog box

Profile Guided Optimization dialog box

To access the **Profile Guided Optimization** dialog box, choose **Tools** > **Intel Compiler** > **Profile Guided Optimization**.

Use the **Profile Guided Optimization** dialog box to set the options for profile guided optimization.

Phase 1 - Instrument: This phase produces an instrumented object file for the profile guided optimization. The command line compiler option for each optimization instrument you choose appears in **Compiler Options**.

- **Enable Function Ordering in the optimized application:** Select this checkbox to enable ordering of static and extern routines using profile information. This optimization specifies the order in which the linker should link the functions of your application. This optimization can improve your application performance by improving code locality and by reducing paging.
- **Enable Static Data Layout in the optimized application:** Select this checkbox to enable ordering of static global data items based on profiling information. This optimization specifies the order in which the linker should link global data of your program. This optimization can improve application performance by improving the locality of static global data, reduce paging of large data sets, and improve data cache use.
- **Instrument with guards for threaded application:** Select this checkbox to produce an instrumented object file that includes the collection of PGO data on applications that use a high level of parallelism.

Selecting an option produces a static profile information file (`.spi`), but also increases the time needed to do a parallel build.

Deselect the checkbox to skip this phase to save time running profile guided optimization. When you skip this phase, you use the existing profile information when running profile guided optimization. For example, you may want to skip this phase when you change the code to fix a bug and the fix doesn't affect the architecture of the project.

Phase 2 - Run Instrumented Application(s): This phase runs the instrumented application produced in the previous phase as well as other applications in the **Applications Invocations** dialog box. To add a new application or edit an existing application in the list, click **Applications Invocations**.

Deselect the checkbox to skip this phase to save time running profile guided optimization. When you skip this phase, you do not run the applications in the list when running profile guided optimization. For example, you might want to skip this phase when you change the code to fix a bug and the fix doesn't affect the architecture of the project.

Phase 3 - Optimize with Profile Data: This phase performs the profile guided optimization.

Deselect the checkbox to skip this phase.

Profile Directory: The directory that contains the profile. Click **Edit** to edit the profile directory or the **Browse** button to browse for the profile directory.

Show this dialog next time: Deselect this checkbox to run profile guided optimization without displaying this dialog box. The profile guided optimization will use these settings.

Save Settings: Click to save your settings.

Run: Click to start the profile guided optimization.

Cancel: Click to close this dialog box without starting the profile guided optimization.

Application Invocations dialog box

To access the **Application Invocations** dialog box, click **Application Invocations...** in the **Profile Guided Optimization** dialog box. Use the **Profile Guided Optimization** dialog box to configure the application options for your application as well add additional applications when you run profile guided optimization.

The list of applications comes from the debug settings of the **Startup Project**.

Merge Environment: Select this checkbox to merge the application environment with the environment defined by the operating system.

To add, edit, or remove an application, click one of the buttons.

Add: Click to add a new application in the **Edit Command** dialog box.

Duplicate: Click after selecting an application to copy its settings so that you can use a different setting.

Edit: Click after selecting an application to change its settings in the **Edit Command** dialog box.

Delete: Click to remove the selected application from the list.

OK: Click to save the settings and close this dialog box.

Cancel: Click to discard the settings and close this dialog box.

Edit Command dialog box

To access the **Edit Command** dialog box, click **Add** or **Edit** in the **Application Invocations** dialog box. Use the **Edit Command** dialog box to add a new or edit an existing application in the **Application Invocations** dialog box.

Command: Add a new or edit an existing application. Click **Edit** to open the **Command** dialog box with a list of macros. Click **Browse** to navigate to another directory that contains the application.

Command Arguments: Enter the arguments required by the application.

Working Directory: Enter a new or edit the working directory for the application. Click **Edit** to open the **Command** dialog box with a list of macros. Click **Browse** to navigate to working directory of the application.

Environment: Enter the environment variable required by this application.

Merge Environment: Select this checkbox to merge the application environment with the environment defined by the operating system.

Load from Debugging Settings: Click to load the debug settings for this application.

OK: Click to save the settings and close this dialog box.

Cancel: Click to discard the settings and close this dialog box.

Command dialog box

To access the **Command** dialog box, click **Edit** in the **Edit Command** dialog box. Use the **Command** dialog box to specify or change the macro used in the application to run as part of the profile guided optimization.

Select a macro from the list and then click one of the buttons.

Macro: Click to show or close the list of available macros.

Insert: Click to use the selected macro.

OK: Click to save the settings and close this dialog box.

Cancel: Click to discard the settings and close this dialog box.

Profile-Guided Optimizations

Code Coverage dialog box

To access the **Code Coverage** dialog box, select **Tools** > **Intel Compiler** > **Code Coverage...**.

Use the **Code Coverage** dialog box to set the code coverage feature.

Phase 1 - Instrument: Select this checkbox to compile your code into an instrumented application.

Select the **Instrument with guards for threaded application** checkbox to produce an instrumented object file that includes the collection of PGO data on applications that use a high level of parallelism.

The compiler option used is shown in **Compiler Options**.

Deselect the **Phase 1 - Instrument** checkbox to skip this phase.

Phase 2 - Run Instrumented Application(s): Select this checkbox to run your instrumented application as well as other applications.

You can specify the options to run with the applications by choosing the **Application Invocations...** button to access the **Applications Invocations** dialog box.

Deselect the **Phase 2 - Run Instrumented Application(s)** checkbox to skip this phase.

Phase 3 - Generate Report: Select this checkbox to generate a report with the results of running the instrumented application.

Choose the **Settings...** button to access the Code Coverage Settings dialog box to configure the settings.

Profile Directory: Where the profile is stored.

Browse: Button to browse for the profile directory.

Show this dialog next time: Choose this button to access the dialog box when you run profile guided optimization.

Save Settings: Choose this button to save your settings.

Run: Choose this button to start the profile guided optimization.

Cancel: Choose this button to close this dialog box without starting the profile guided optimization.

code coverage Tool

Options: Code Coverage dialog box

To access the **Code Coverage** page, click **Tools** > **Options** and then select **Intel Compilers and Tools** > **Code Coverage**.

Use this page to specify settings for code coverage. These settings are used when you run an analysis.

Code Coverage Options

Use the available options to:

- Select colors to be used to show covered and uncovered code.
- Enable or disable the progress meter.
- Set the email address and name of the web page owner.

General

Show Code Coverage Dialog: Specify whether to display the Code Coverage dialog box when you begin code coverage.

Profmerge Options

Suppress Startup Banner: Specify whether version information is displayed.

Verbose: Specify whether additional informational and warning messages should be displayed.

See Also

Using Code Coverage in Microsoft Visual Studio*

Code Coverage dialog box

Code Coverage Tool

Code Coverage Settings dialog box

To access the **Code Coverage Settings** dialog box, choose the **Settings** button in the **Code Coverage** dialog box. Use the **Code Coverage Settings** dialog box to specify settings for the generated report.

Code Coverage options

Ignore Object Unwind Handlers: Set to **True** to ignore the object unwind handlers.

Show Execution Counts: Set to **True** to show the dynamic execution counts in the report.

Treat Partially-covered Code As Fully Covered Code: Set to **True** to treat partially covered code as fully covered code.

Profmerge options

Dump Profile Information: Set to **True** to include profile information in the report.

Exclude Functions: Enter the functions that will be excluded from the profile. The functions must be separated by a comma (","). A period (".") can be used as a wildcard character in function names.

OK: Click to save your settings and close this dialog box.

Cancel: Click to discard the settings and close this dialog box.

code coverage Tool

Options: Optimization Reports dialog box

To access the **Optimization Reports** page, click **Tools** > **Options** and then select**Intel Compilers and Tools** > **Optimization Reports**. Use this page to specify how you want optimization reporting to appear.

This page, in conjunction with the **Diagnostics** property page for your project or solution, defines settings for optimization report viewing in Visual Studio*.

General

Always Show Compiler Inline Report: Specify if the Compiler Inline Report appears after building or rebuilding your solution or project when inline diagnostics are present.

Always Show Compiler Optimization Report: Specify if Compiler Optimization Report appears after building or rebuilding your solution or project when optimization diagnostics are present. This option has higher priority than **Always Show Compiler Inline Report**. If both options are set to True, then this window has focus by default.

Show Optimization Notes in Text Editor Margin: Specify if optimization notes appear in the editor as source code annotations.

Optimization Notes in Text Editor

Collapse by Default: Specify if optimization notes appear expanded or collapsed by default.

Show Optimization Notes: Specify if source code annotations appear in the editor.

Site: Specify where optimization notes appear in the editor. Select from one of the following options:

- **Caller Site**
- **Callee Site**
- **Caller Site and Callee Site**

Optimization Reports: Enabling in Visual Studio*

Using Xcode* (macOS*)

Creating an Xcode* Project

The following topic applies to Xcode*.

To create a new Xcode* project:

1. Launch the Xcode* application.
2. Select **File** > **New** > **Project...**

   The **Choose a template for your new project** window opens.

3. In the left pane, select **macOS*** > **Application**.
4. Select a template, for example: **Command Line Tool**, and click **Next**.
5. Name your project, for example: Hello World, then enter a string for the **Organization Name** and **Organization Identifier** and select the C or C++ language (you can change it to Fortran later). Click **Next**.
6. Specify a directory for your project, and optionally select **Create local git repository for this project** to place your project under version control.
7. Click **Create**.

Xcode* creates the named project directory, with an `.xcodeproj` extension. Your new project directory contains a `main.cpp` source file and other project files. You can delete `main.cpp`.

Each Xcode* project has its own **Project Editor** window that displays project source files, targets, and executables.

Adding a New File

Selecting the Intel® Compiler

The following topic applies to Xcode*.

To select the Intel®Fortran Compiler:

1. Select the target you want to change and click **Build Rules**.
2. Add a new rule by clicking **Editor** > **Add Build Rule** or pressing the **+** button.
3. Under **Process**, choose **Fortran source files** .
4. Under **Using**, select one of the options for the **Intel® Fortran Compiler**:
   - ***Major_Version***, such as **19.1**: The most recently installed compiler, even if it is not the latest release.
   - **Latest Release**: The latest released compiler available on your system. This is useful when you have multiple installations of the Intel compiler and want to use the version most recently released by Intel.
   - ***Major_Version.n.nnn***: A specific package, such as 19.1.0.000. This is useful when you have multiple packages of one major version installed.

NOTE If the Intel® Compiler does not show up in the drop-down list, it may mean that the compiler does not support your version of Xcode*. To enable the Intel® Compiler in Xcode* specify the Xcode path during installation and restart the program. The installer checks for the supported Xcode* version and warns you in the case of an unsupported version.

NOTE

- If you select a tool that does not support the source file type, that source file type is processed by a later rule that specifies that type.
- Once you have set a new build rule for the Xcode* to use the Intel® Fortran Compiler for Fortran source files, you can view and adjust the option settings.

See Also

Setting Compiler Options

Adding a New File

The following topic applies to Fortran for Xcode*.

To add a new Fortran file:

1. In the Xcode* Project Editor, select **File** > **New** > **File...**
2. Select **Fortran** in the left pane, and then select **Fortran Fixed Format File** or **Fortran Free Format File** in the upper right pane. Click **Next**.
3. Enter a name for the file, including a Fortran source file extension, such as `.f90`, and select a location for the new file. Click **Create**.

Building the Target

The following topic applies to Xcode*.

A single project can contain multiple targets. The active target determines how your project is built. This topic describes how to build the target using the Xcode* IDE and documents the build steps using the `xcodebuild` command line utility.

> **NOTE** Starting with the 19.0 release of the Intel®Fortran Compiler, macOS* 32-bit applications are no longer supported. If you want to compile 32-bit applications, you must use an earlier version of the compiler and you must use Xcode* 9.4 or earlier.

Building Using the Xcode* IDE

1. Select the target in the project editor under **Targets**.
2. Select **Product** > **Build**.
3. To view the results of your build, click the **Log Navigator** button.

You can change the compilation order of the files in an Xcode* target. This may be necessary to compile Fortran source files that define modules (producing `.MOD` files). These can be used by Fortran sources that use the modules. To re-order the files listed under a target's **Compile Sources**, click a source file and drag it before, or after other compilations.

Building From the Command Line Using the xcodebuild Utility

You can use the `xcodebuild` utility to build a target. This utility uses the Xcode* project settings to build target projects from the command line. If you have previously configured your Xcode* project to build with the Intel compiler, `xcodebuild` invokes it from the command line.

To build from the command line:

1. Check that the Xcode* project is configured to use the Intel® Fortran Compiler.
2. Launch a terminal window from the finder by selecting **Applications** > **Utilities** > **Terminal** .
3. Change directories to the directory containing the Xcode* project file (`.xcodeproj`).
4. If you have multiple versions of Xcode*, use the **xcode-select** utility to verify the current Xcode* version.
5. Issue an `xcodebuild` command. For example:

```
xcodebuild -project HelloWorld.xcodeproj -target HelloWorld -configuration Debug
```

6. Run the program built in the example from the previous step by entering the following:

```
./build/Debug/HelloWorld
```

For more information, refer to the `xcodebuild` man page.

Setting the Executable's Architecture

Before building a 64-bit executable from within Xcode*, you may need to edit the executable's target architecture. To change the **Architectures** setting:

1. Click the target you want to change in the project editor under **Targets** and select the **Build Settings** tab.

2. Under **Architectures**, select the desired architecture.

NOTE The Intel® Fortran Compiler generates code solely for Intel® architectures.

Setting Compiler Options

The following topic applies to Xcode*.

To use the Xcode* environment to set compiler options, including options specific to Intel® architecture:

1. Select a target.
2. Under the **Build Settings** tab, click **All**.
3. Scroll down to the list of Intel® Fortran Compiler categories.
4. To set an Intel®Fortran Compiler option in the Floating Point category, scroll down to display **Floating Point**.
5. Select a **Setting**, such as **Extend Precision of Single-Precision Constants**, and set the option's state. If the **Quick Help** inspector is visible, information about the selected option appears under **Quick Help**.

The next time you build your project, the selected options are used in the compilation.

NOTE To view the settings that have changed from the established defaults, select the **Levels** button under **Build Settings**.

Running the Executable

The following topic applies to Xcode*.

Once you have built your Xcode* project, click the **Run** button. The output from the executable is displayed. This button runs the configuration currently associated with the button. Use the **Scheme Editor** to change the configuration associated with the button.

Tip To open the **Scheme Editor**, select **Product** > **Scheme...** > **Edit Scheme...**

Using Dynamic Libraries

Using the Dynamic Libraries does not assume that the Apple* System Integrity Protection feature purges environment variables, such as `DYLD_LIBRARY_PATH`, when launching the protected process. Refer to the https://developer.apple.com/library/archive/documentation/Security/Conceptual/System_Integrity_Protection_Guide/Introduction/Introduction.html for more information. Xcode must take this into account and set the proper environment variables in the Xcode environment.

You can build your Xcode project with the `-shared-intel` compiler option to link with the Intel dynamic libraries. Build your project with the `-qopenmp` or `-parallel` option to link in `libiomp5.dylib`. If you do this, you need to set Xcode build option `Runpath Search path` to an appropriate folder with the compiler and performance libraries, or specify the `DYLD_LIBRARY_PATH` environment variable in the Xcode environment.

To add the environment variable:

1. Open the **Scheme Editor** and select the **Run** action.
2. On the **Arguments** tab, under **Environment Variables**, click the **+** button.
3. Add `DYLD_LIBRARY_PATH`. Set the value to the full path to the Intel compiler's `/lib` directory.

NOTE If you build your project with the `-shared-intel`, `-qopenmp`, or `-parallel` compiler option without setting the `DYLD_LIBRARY_PATH` environment variable, a *library not found* error message results at runtime. Depending on your application, the error message may refer to a library other than the one noted in this example:

```
dyld: Library not loaded: libiomp5.dylib
Referenced
from: /Users/test/hello_world
Reason: image not found
```

Due to the Apple System Integrity Protection you may need to set the `DYLD_LIBRARY_PATH` explicitly in the launch string, or configure the `Runpath Search path` build option.

parallel, Qparallel option

Using Intel® Performance Libraries with Xcode*

The following topic applies to Fortran for Xcode*.

The Intel® Fortran Compiler is bundled with the Intel® Math Kernel Library (Intel® MKL). You can access this library in Xcode* by using the **Use Intel® Math Kernel Library** property, located in the **Build Settings** > **Performance Library Build Components**.

The **Use Intel® Math Kernel Library** property provides the following options in a drop-down menu:

- **None:** Disables the use of the Intel® MKL.
- **Use threaded Intel® Math Kernel Library:** Links using the threaded version of the library.
- **Use non-threaded Intel® Math Kernel Library:** Links using the non-threaded version of the library.

For more information, see the Intel® MKL documentation.

Part II

Compiler Reference

Compiler Limits

The amount of data storage, the size of arrays, and the total size of executable programs are limited only by the amount of process virtual address space available, as determined by system parameters.

The table below shows the limits to the size and complexity of a single Intel® Fortran program unit and to individual statements contained within it:

Language Element	Limit
Actual number of arguments per CALL or function reference	Limited only by memory constraints
Arguments in a function reference in a specification expression	255
Array dimensions	31 (The Fortran 2008 standard supports a maximum array dimension of 15.)
Array elements per dimension	2**31-1 on systems using IA-32 architecture 2**63-1 on systems using Intel® 64 architecture Limited by current memory configuration.
Character lengths	2**31-1 on systems using IA-32 architecture 2**63-1 on systems using Intel® 64 architecture
Constants: character and Hollerith	7198
Constants: characters read in list-directed I/O	2048 characters
Continuation lines	No fixed limit; at least 255 lines of 132 or fewer characters. Longer lines may reduce the number of allowed continuations, subject to the limit on lexical tokens per statement.
Data and I/O implied DO nesting	31
DO, CASE, FORALL, WHERE, and block IF statement nesting (combined)	512
DO loop index variable	9,223,372,036,854,775,807= 2**63-1

Language Element	Limit
Format group nesting	8
Fortran source line length	fixed form: 72 (or 132 if `/extend_source` is in effect) characters free form: 7200 characters
INCLUDE file nesting	20 levels
Labels in computed or assigned GOTO list	Limited only by memory constraints
Lexical tokens per statement	40000
Named common blocks	Limited only by memory constraints
Nesting of array constructor implied DOs	31
Nesting of input/output implied DOs	31
Nesting of interface blocks	Limited only by memory constraints
Nesting of DO, IF, or CASE constructs	Limited only by memory constraints
Nesting of parenthesized formats	Limited only by memory constraints
Number of arguments to MIN and MAX	Limited only by memory constraints
Number of digits in a numeric constant	Limited by statement length
Parentheses nesting in expressions	Limited only by memory constraints
Structure nesting	30
Symbolic name length	63 characters
Width field for a numeric edit descriptor	2**15-1 on systems using IA-32 architecture 2**31-1 on systems using Intel® 64 architecture For limits of other edit descriptor fields, see Forms for Data Edit Descriptors.

For more information on memory limits for large data objects, see:

- The AUTOMATIC statement
- The /F compiler option
- The heap-array compiler option
- The product Release Notes

Using Visual Studio* IDE Automation Objects (Windows*)

This topic briefly describes the Automation interfaces provided by Intel® Visual Fortran. Automation interfaces are programmable objects used to access underlying IDE components and projects to provide experienced developers with a means of automating common tasks and allow a finer degree of control over the IDE and the Fortran projects being used within it.

You can use the Visual Studio* Object Browser (**View** > **Object Browser**) to view an object and its associated properties. Open the following in the browser: **Browse** > **Edit Custom Component Set** > **.NET** > **Microsoft.VisualStudio.VFProject**.

NOTE
The objects listed here are provided as an advanced feature for developers who are already familiar with using Automation objects and the Visual Studio* object model.

Object	Description
IVFCollection	Contains the functionality that can be exercised on a collections object.
VFConfiguration	Programmatically accesses the properties in the **General** property page of a project's Property Pages dialog box. This object also allows access to the tools used to build this configuration.
VFCustomBuildTool	Programmatically accesses the properties in the **Custom Build Step** property page in a project's Property Pages dialog box.
VFDebugSettings	Contains properties that allow the user to programmatically manipulate the settings in the **Debug** property page.
VFFile	Describes the operations that can take place on a file in the active project.
VFFileConfiguration	Contains build information about a file (VFFile object), including such things as what tool is attached to the file for that configuration.
VFFilter	Exposes the functionality on a folder in Solution Explorer for an Intel® Visual Fortran project.
VFFortranCompilerTool	Exposes the functionality of the IFORT tool.
VFFortranCompilerVersion	Provides access to properties relating to the Intel® Visual Fortran compiler version.
VFLibrarianTool	Exposes the functionality of the LIB tool.
VFLinkerTool	Exposes the functionality of the LINK tool.
VFManifestTool	Programmatically accesses the properties in the **Manifest Tool** folder of a project's Property Pages dialog box.
VFMidlTool	Programmatically accesses the properties in the **MIDL folder** of a project's Property Pages dialog box.
VFPlatform	Provides access to properties relating to supported platforms.
VFPreBuildEventTool	Programmatically accesses the properties on the **Pre-Build Event** property page, in the Build Events folder in a project's Property Pages dialog box.

VFPreLinkEventTool	Programmatically accesses the properties on the **PreLink Event** property page, in the Build Events folder in a project's Property Pages dialog box.
VFPostBuildEventTool	Programmatically accesses the properties on the **Post-Build Event** property page, in the Build Events folder in a project's Property Pages dialog box.
VFProject	Exposes the properties on an Intel® Visual Fortran project
VFResourceCompilerTool	Programmatically accesses the properties in the Resources folder in a project's Property Pages dialog box.

The following example, written in Visual Basic*, demonstrates how to use automation objects to modify the list of available platforms and versions in the Visual Studio* IDE Configuration Manager:

```
Imports System
Imports EnvDTE
Imports EnvDTE80
Imports System.Diagnostics
Imports Microsoft.VisualStudio.VFProject
Imports System.Collections
Public Module MultiPV
    ' Create a Console application before executing this module
    ' Module demonstrates Multi Platform & Multi Version Automation Support
    ' Variable definition
    Dim Prj As Project          ' VS project
    Dim VFPrj As VFProject     ' Intel VF project
    Dim o As Object             ' Object
    Sub run()
        ' Get the Project
        Prj  = DTE.Solution.Projects.Item(1)
        '
        ' Get Intel VF project
        VFPrj  = Prj.Object
        '
        ' Get list of Supported platforms
        Dim pList As ArrayList = New ArrayList()    ' list of platforms
        Dim cList As ArrayList = New ArrayList()    ' lost of compilers
        Dim i As Integer
        pList  = getSupportedPlatforms()
        For i = 0 To pList.Count - 1
            cList  = getCompilers(pList.Item(i))
            printCompilers(pList.Item(i), cList)
        Next
        '
        ' Add configurations - x64
        For i = 0 To pList.Count - 1
            If pList.Item(i) <> "Win32" Then
                addConfiguration(pList.Item(i))
            End If
        Next
        Dim cfgsList As ArrayList = New ArrayList() ' list of configurations
        cfgsList = getAllConfigurations()
        '

Compiler Options

The Intel®Fortran compiler supports many compiler options you can use in your applications.

In this section, we provide the following:

- Lists of new options and lists of deprecated or removed options
- An alphabetical list of compiler options that includes their short descriptions
- General rules for compiler options and the conventions we use when referring to options
- Details about what appears in the compiler option descriptions
- A description of each compiler option. The descriptions appear under the option's functional category. Within each category, the options are listed in alphabetical order.

New Options

This topic lists the options or option settings that provide new functionality in this release.

If no label appears, the option is available on all supported systems.

If "only" appears in the label, the option is only available on the identified system.

For more details on the options, refer to the individual option descriptions.

For information on conventions used in this table, see Notational Conventions.

New compiler options or option settings are listed in tables below:

- The first table lists new options or option settings that are available on Windows* systems.
- The second table lists new options or option settings that are available on Linux* and macOS* systems. If an option is only available on one of these operating systems, it is labeled.

Windows* Options	Description	Default
`/assume`	New setting [no]old_inquire_recl has been added. It determines the value of the RECL= specifier on an INQUIRE statement for an unconnected unit or a unit connected for stream access. New setting [no]old_ldout_zero has been added. It determines the format of a floating-point zero produced by list-directed output. old_ldout_zero uses exponential format, noold_ldout_zero uses fractional format.	`/assume:old_inquire_recl` `/assume:old_ldout_zero`
`/check`	New setting [no]udio_iostat has been added. It determines whether conformance checking occurs when user defined derived type input/output routines are executed.	`/nocheck`
`/Qauto-arch`	Tells the compiler to generate multiple, feature-specific auto-dispatch code paths for x86 architecture processors if there is a performance benefit.	OFF

Windows* Options	Description	Default
/Qconditional-branch=*keyword*	Lets you identify and fix code that may be vulnerable to speculative execution side-channel attacks, which can leak your secure data as a result of bad speculation of a conditional branch direction.	/Qconditional-branch:keep

Linux* and macOS* Options	Description	Default
-assume	New setting [no]old_inquire_recl has been added. It determines the value of the RECL= specifier on an INQUIRE statement for an unconnected unit or a unit connected for stream access. New setting [no]old_ldout_zero has been added. It determines the format of a floating-point zero produced by list-directed output. old_ldout_zero uses exponential format, noold_ldout_zero uses fractional format.	-assumeold_inquire_recl -assume old_ldout_zero
-check	New setting [no]udio_iostat has been added. It determines whether conformance checking occurs when user defined derived type input/output routines are executed.	-nocheck
-mauto-arch	Tells the compiler to generate multiple, feature-specific auto-dispatch code paths for x86 architecture processors if there is a performance benefit.	OFF
-mconditional-branch=*keyword*	Lets you identify and fix code that may be vulnerable to speculative execution side-channel attacks, which can leak your secure data as a result of bad speculation of a conditional branch direction.	-mconditional-branch=keep

Alphabetical List of Compiler Options

The following table lists all the current compiler options in alphabetical order.

4Nportlib, 4Yportlib	Determines whether the compiler links to the library of portability routines.
align	Tells the compiler how to align certain data items.
allow	Determines whether the compiler allows certain behaviors.
altparam	Allows alternate syntax (without parentheses) for PARAMETER statements.
ansi-alias, Qansi-alias	Tells the compiler to assume certain rules of the Fortran standard regarding aliasing and array bounds.
arch	Tells the compiler which features it may target, including which instruction sets it may generate.
assume	Tells the compiler to make certain assumptions.
auto	Causes all local, non-SAVEd variables to be allocated to the run-time stack.
auto-scalar, Qauto-scalar	Causes scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL that do not have the SAVE attribute to be allocated to the run-time stack.
ax, Qax	Tells the compiler to generate multiple, feature-specific auto-dispatch code paths for Intel® processors if there is a performance benefit.
Bdynamic	Enables dynamic linking of libraries at run time.
bigobj	Increases the number of sections that an object file can contain.
bintext	Places a text string into the object file (.obj) being generated by the compiler.
B	Specifies a directory that can be used to find include files, libraries, and executables.
Bstatic	Enables static linking of a user's library.
Bsymbolic	Binds references to all global symbols in a program to the definitions within a user's shared library.
Bsymbolic-functions	Binds references to all global function symbols in a program to the definitions within a user's shared library.
ccdefault	Specifies the type of carriage control used when a file is displayed at a terminal screen.
check	Checks for certain conditions at run time.
coarray, Qcoarray	Enables the coarray feature.
coarray-config-file, Qcoarray-config-file	Specifies the name of a Message Passing Interface (MPI) configuration file.
coarray-num-images, Qcoarray-num-images	Specifies the default number of images that can be used to run a coarray executable.
complex-limited-range, Qcomplex-limited-range	Determines whether the use of basic algebraic expansions of some arithmetic operations involving data of type COMPLEX is enabled.
convert	Specifies the format of unformatted files containing numeric data.
c	Prevents linking.

cxxlib	Determines whether the compiler links using the C++ run-time libraries provided by gcc.
dbglibs	Tells the linker to search for unresolved references in a debug run-time library.
D	Defines a symbol name that can be associated with an optional value.
debug (Linux* and macOS*)	Enables or disables generation of debugging information.
debug (Windows*)	Enables or disables generation of debugging information.
debug-parameters	Tells the compiler to generate debug information for PARAMETERs used in a program.
diag, Qdiag	Controls the display of diagnostic information during compilation.
diag-dump, Qdiag-dump	Tells the compiler to print all enabled diagnostic messages.
diag-error-limit, Qdiag-error-limit	Specifies the maximum number of errors allowed before compilation stops.
diag-file, Qdiag-file	Causes the results of diagnostic analysis to be output to a file.
diag-file-append, Qdiag-file-append	Causes the results of diagnostic analysis to be appended to a file.
diag-id-numbers, Qdiag-id-numbers	Determines whether the compiler displays diagnostic messages by using their ID number values.
diag-once, Qdiag-once	Tells the compiler to issue one or more diagnostic messages only once.
d-lines, Qd-lines	Compiles debug statements.
dll	Specifies that a program should be linked as a dynamic-link (DLL) library.
double-size	Specifies the default KIND for DOUBLE PRECISION and DOUBLE COMPLEX declarations, constants, functions, and intrinsics.
dryrun	Specifies that driver tool commands should be shown but not executed.
dumpmachine	Displays the target machine and operating system configuration.
dynamiclib	Invokes the libtool command to generate dynamic libraries.
dynamic-linker	Specifies a dynamic linker other than the default.
dyncom, Qdyncom	Enables dynamic allocation of common blocks at run time.
E	Causes the preprocessor to send output to stdout.
EP	Causes the preprocessor to send output to stdout, omitting #line directives.
exe	Specifies the name for a built program or dynamic-link library.
extend-source	Specifies the length of the statement field in a fixed-form source file.
extfor	Specifies file extensions to be processed by the compiler as Fortran files.
extfpp	Specifies file extensions to be recognized as a file to be preprocessed by the Fortran preprocessor.
extlnk	Specifies file extensions to be passed directly to the linker.
F (macOS*)	Adds a framework directory to the head of an include file search path.

F (Windows*)	Specifies the stack reserve amount for the program.
f66	Tells the compiler to apply FORTRAN 66 semantics.
f77rtl	Tells the compiler to use the run-time behavior of FORTRAN 77.
falias, Oa	Specifies whether or not a procedure call may have hidden aliases of local variables not supplied as actual arguments.
falign-functions, Qfnalign	Tells the compiler to align procedures on an optimal byte boundary.
falign-loops, Qalign-loops	Aligns loops to a power-of-two byte boundary.
falign-stack	Tells the compiler the stack alignment to use on entry to routines.
Fa	Specifies that an assembly listing file should be generated.
FA	Specifies the contents of an assembly listing file.
fast	Maximizes speed across the entire program.
fast-transcendentals, Qfast-transcendentals	Enables the compiler to replace calls to transcendental functions with faster but less precise implementations.
fasynchronous-unwind-tables	Determines whether unwind information is precise at an instruction boundary or at a call boundary.
fcode-asm	Produces an assembly listing with machine code annotations.
fcommon	Determines whether the compiler treats common symbols as global definitions.
Fd	Lets you specify a name for a program database (PDB) file created by the compiler.
feliminate-unused-debug-types, Qeliminate-unused-debug-types	Controls the debug information emitted for types declared in a compilation unit.
fexceptions	Enables exception handling table generation.
ffat-lto-objects	Determines whether a fat link-time optimization (LTO) object, containing both intermediate language and object code, is generated during an interprocedural optimization compilation (-c –ipo).
ffnalias, Ow	Determines whether aliasing is assumed within functions.
fimf-absolute-error, Qimf-absolute-error	Defines the maximum allowable absolute error for math library function results.
fimf-accuracy-bits, Qimf-accuracy-bits	Defines the relative error for math library function results, including division and square root.
fimf-arch-consistency, Qimf-arch-consistency	Ensures that the math library functions produce consistent results across different microarchitectural implementations of the same architecture.
fimf-domain-exclusion, Qimf-domain-exclusion	Indicates the input arguments domain on which math functions must provide correct results.
fimf-force-dynamic-target, Qimf-force-dynamic-target	Instructs the compiler to use run-time dispatch in calls to math functions.
fimf-max-error, Qimf-max-error	Defines the maximum allowable relative error for math library function results, including division and square root.

fimf-precision, Qimf-precision	Lets you specify a level of accuracy (precision) that the compiler should use when determining which math library functions to use.
fimf-use-svml, Qimf-use-svml	Instructs the compiler to use the Short Vector Math Library (SVML) rather than the Intel® Math Library (LIBM) to implement math library functions.
finline-functions	Enables function inlining for single file compilation.
finline-limit	Lets you specify the maximum size of a function to be inlined.
finline	Tells the compiler to inline functions declared with !DIR$ ATTRIBUTES FORCEINLINE .
finstrument-functions, Qinstrument-functions	Determines whether routine entry and exit points are instrumented.
fixed	Specifies source files are in fixed format.
fkeep-static-consts, Qkeep-static-consts	Tells the compiler to preserve allocation of variables that are not referenced in the source.
fltconsistency	Enables improved floating-point consistency.
fma, Qfma	Determines whether the compiler generates fused multiply-add (FMA) instructions if such instructions exist on the target processor.
fmath-errno	Tells the compiler that errno can be reliably tested after calls to standard math library functions.
fmerge-constants	Determines whether the compiler and linker attempt to merge identical constants (string constants and floating-point constants) across compilation units.
fmerge-debug-strings	Causes the compiler to pool strings used in debugging information.
fminshared	Specifies that a compilation unit is a component of a main program and should not be linked as part of a shareable object.
fmpc-privatize	Enables or disables privatization of all static data for the MultiProcessor Computing environment (MPC) unified parallel runtime.
fnsplit, Qfnsplit	Enables function splitting.
fomit-frame-pointer, Oy	Determines whether EBP is used as a general-purpose register in optimizations.
foptimize-sibling-calls	Determines whether the compiler optimizes tail recursive calls.
fpconstant	Tells the compiler that single-precision constants assigned to double-precision variables should be evaluated in double precision.
fpe-all	Allows some control over floating-point exception handling for each routine in a program at run-time.
fpe	Allows some control over floating-point exception handling for the main program at run-time.
fpic	Determines whether the compiler generates position-independent code.
fpie	Tells the compiler to generate position-independent code. The generated code can only be linked into executables.
fp-model, fp	Controls the semantics of floating-point calculations.
fpp-name	Lets you specify an alternate preprocessor to use with Fortran.

fp-port, Qfp-port	Rounds floating-point results after floating-point operations.
fpp	Runs the Fortran preprocessor on source files before compilation.
fprotect-parens, Qprotect-parens	Determines whether the optimizer honors parentheses when floating-point expressions are evaluated.
fpscomp	Controls whether certain aspects of the run-time system and semantic language features within the compiler are compatible with Intel® Fortran or Microsoft* Fortran PowerStation.
fp-speculation, Qfp-speculation	Tells the compiler the mode in which to speculate on floating-point operations.
fp-stack-check, Qfp-stack-check	Tells the compiler to generate extra code after every function call to ensure that the floating-point stack is in the expected state.
free	Specifies source files are in free format.
fsource-asm	Produces an assembly listing with source code annotations.
fstack-protector	Enables or disables stack overflow security checks for certain (or all) routines.
fstack-security-check	Determines whether the compiler generates code that detects some buffer overruns.
ftrapuv , Qtrapuv	Initializes stack local variables to an unusual value to aid error detection.
ftz, Qftz	Flushes subnormal results to zero.
fuse-ld	Tells the compiler to use a different linker instead of the default linker (ld).
fverbose-asm	Produces an assembly listing with compiler comments, including options and version information.
fvisibility	Specifies the default visibility for global symbols or the visibility for symbols in a file.
fzero-initialized-in-bss, Qzero-initialized-in-bss	Determines whether the compiler places in the DATA section any variables explicitly initialized with zeros.
gcc-name	Lets you specify the name of the gcc compiler that should be used to set up the link-time environment, including the location of standard libraries.
gdwarf	Lets you specify a DWARF Version format when generating debug information.
Ge	Enables stack-checking for all functions. This is a deprecated option. The replacement option is /Gs0.
gen-depformat	Specifies the form for the output generated when option gen-dep is specified.
gen-depshow	Determines whether certain features are excluded from dependency analysis. Currently, it only applies to intrinsic modules.
gen-dep	Tells the compiler to generate build dependencies for the current compilation.
gen-interfaces	Tells the compiler to generate an interface block for each routine in a source file.
GF	Enables read-only string-pooling optimization.

global-hoist, Qglobal-hoist	Enables certain optimizations that can move memory loads to a point earlier in the program execution than where they appear in the source.
grecord-gcc-switches	Causes the command line options that were used to invoke the compiler to be appended to the DW_AT_producer attribute in DWARF debugging information.
GS	Determines whether the compiler generates code that detects some buffer overruns.
Gs	Lets you control the threshold at which the stack checking routine is called or not called.
gsplit-dwarf	Creates a separate object file containing DWARF debug information.
g	Tells the compiler to generate a level of debugging information in the object file.
guard	Enables the control flow protection mechanism.
guide, Qguide	Lets you set a level of guidance for auto-vectorization, auto parallelism, and data transformation.
guide-data-trans, Qguide-data-trans	Lets you set a level of guidance for data transformation.
guide-file, Qguide-file	Causes the results of guided auto parallelism to be output to a file.
guide-file-append, Qguide-file-append	Causes the results of guided auto parallelism to be appended to a file.
guide-opts, Qguide-opts	Tells the compiler to analyze certain code and generate recommendations that may improve optimizations.
guide-par, Qguide-par	Lets you set a level of guidance for auto parallelism.
guide-vec, Qguide-vec	Lets you set a level of guidance for auto-vectorization.
gxx-name	Lets you specify the name of the g++ compiler that should be used to set up the link-time environment, including the location of standard libraries.
heap-arrays	Puts automatic arrays and arrays created for temporary computations on the heap instead of the stack.
help	Displays all available compiler options or a category of compiler options.
homeparams	Tells the compiler to store parameters passed in registers to the stack.
hotpatch	Tells the compiler to prepare a routine for hotpatching.
idirafter	Adds a directory to the second include file search path.
iface	Specifies the default calling convention and argument-passing convention for an application.
init, Qinit	Lets you initialize a class of variables to zero or to various numeric exceptional values.
inline-factor, Qinline-factor	Specifies the percentage multiplier that should be applied to all inlining options that define upper limits.
inline-forceinline, Qinline-forceinline	Instructs the compiler to force inlining of functions suggested for inlining whenever the compiler is capable doing so.
inline-level, Ob	Specifies the level of inline function expansion.

inline-max-per-compile, Qinline-max-per-compile	Specifies the maximum number of times inlining may be applied to an entire compilation unit.
inline-max-per-routine, Qinline-max-per-routine	Specifies the maximum number of times the inliner may inline into a particular routine.
inline-max-size, Qinline-max-size	Specifies the lower limit for the size of what the inliner considers to be a large routine.
inline-max-total-size, Qinline-max-total-size	Specifies how much larger a routine can normally grow when inline expansion is performed.
inline-min-caller-growth, Qinline-min-caller-growth	Lets you specify a procedure size n for which procedures of size <= n do not contribute to the estimated growth of the caller when inlined.
inline-min-size, Qinline-min-size	Specifies the upper limit for the size of what the inliner considers to be a small routine.
inline	Specifies the level of inline function expansion.
intconstant	Tells the compiler to use FORTRAN 77 semantics to determine the kind parameter for integer constants.
integer-size	Specifies the default KIND for integer and logical variables.
intel-freestanding	Lets you compile in the absence of a gcc environment.
intel-freestanding-target-os	Lets you specify the target operating system for compilation.
ip, Qip	Determines whether additional interprocedural optimizations for single-file compilation are enabled.
ip-no-inlining, Qip-no-inlining	Disables full and partial inlining enabled by interprocedural optimization options.
ip-no-pinlining, Qip-no-pinlining	Disables partial inlining enabled by interprocedural optimization options.
ipo, Qipo	Enables interprocedural optimization between files.
ipo-c, Qipo-c	Tells the compiler to optimize across multiple files and generate a single object file.
ipo-jobs, Qipo-jobs	Specifies the number of commands (jobs) to be executed simultaneously during the link phase of Interprocedural Optimization (IPO).
ipo-S, Qipo-S	Tells the compiler to optimize across multiple files and generate a single assembly file.
ipo-separate, Qipo-separate	Tells the compiler to generate one object file for every source file.
I	Specifies an additional directory for the include path.
isystem	Specifies a directory to add to the start of the system include path.
libdir	Controls whether linker options for search libraries are included in object files generated by the compiler.
libs	Tells the compiler which type of run-time library to link to.
link	Passes user-specified options directly to the linker at compile time.
list-line-len	Specifies the line length for the listing generated when option list is specified.

list-page-len	Specifies the page length for the listing generated when option list is specified.
list	Tells the compiler to create a listing of the source file.
logo	Displays the compiler version information.
l	Tells the linker to search for a specified library when linking.
L	Tells the linker to search for libraries in a specified directory before searching the standard directories.
m32, m64 , Qm32, Qm64	Tells the compiler to generate code for a specific architecture.
m80387	Specifies whether the compiler can use x87 instructions.
map-opts, Qmap-opts	Maps one or more compiler options to their equivalent on a different operating system.
map	Tells the linker to generate a link map file.
march	Tells the compiler to generate code for processors that support certain features.
masm	Tells the compiler to generate the assembler output file using a selected dialect.
mauto-arch, Qauto-arch	Tells the compiler to generate multiple, feature-specific auto-dispatch code paths for x86 architecture processors if there is a performance benefit.
mbranches-within-32B-boundaries, Qbranches-within-32B-boundaries	Tells the compiler to align branches and fused branches on 32-byte boundaries for better performance.
mcmodel	Tells the compiler to use a specific memory model to generate code and store data.
mconditional-branch, Qconditional-branch	Lets you identify and fix code that may be vulnerable to speculative execution side-channel attacks, which can leak your secure data as a result of bad speculation of a conditional branch direction.
MDs	Tells the linker to search for unresolved references in a single-threaded, dynamic-link run-time library. This is a deprecated option. There is no replacement option.
MD	Tells the linker to search for unresolved references in a multithreaded, dynamic-link run-time library.
mdynamic-no-pic	Generates code that is not position-independent but has position-independent external references.
minstruction, Qinstruction	Determines whether MOVBE instructions are generated for certain Intel processors.
mkl, Qmkl	Tells the compiler to link to certain libraries in the Intel® Math Kernel Library (Intel® MKL). On Windows systems, you must specify this option at compile time.
module	Specifies the directory where module files should be placed when created and where they should be searched for.
momit-leaf-frame-pointer	Determines whether the frame pointer is omitted or kept in leaf functions.
mp1, Qprec	Improves floating-point precision and consistency.

mstringop-inline-threshold, Qstringop-inline-threshold	Tells the compiler to not inline calls to buffer manipulation functions such as memcpy and memset when the number of bytes the functions handle are known at compile time and greater than the specified value.
mstringop-strategy, Qstringop-strategy	Lets you override the internal decision heuristic for the particular algorithm used when implementing buffer manipulation functions such as memcpy and memset.
m	Tells the compiler which features it may target, including which instruction sets it may generate.
MT	Tells the linker to search for unresolved references in a multithreaded, static run-time library.
mtune, tune	Performs optimizations for specific processors but does not cause extended instruction sets to be used (unlike -march).
multiple-processes, MP	Creates multiple processes that can be used to compile large numbers of source files at the same time.
names	Specifies how source code identifiers and external names are interpreted.
no-bss-init, Qnobss-init	Tells the compiler to place in the DATA section any uninitialized variables and explicitly zero-initialized variables.
nodefaultlibs	Prevents the compiler from using standard libraries when linking.
nofor-main	Specifies that the main program is not written in Fortran.
nolib-inline	Disables inline expansion of standard library or intrinsic functions.
nostartfiles	Prevents the compiler from using standard startup files when linking.
nostdlib	Prevents the compiler from using standard libraries and startup files when linking.
object	Specifies the name for an object file.
Od	Disables all optimizations.
Ofast	Sets certain aggressive options to improve the speed of your application.
Os	Enables optimizations that do not increase code size; it produces smaller code size than O2.
O	Specifies the code optimization for applications.
o	Specifies the name for an output file.
Ot	Enables all speed optimizations.
pad, Qpad	Enables the changing of the variable and array memory layout.
pad-source, Qpad-source	Specifies padding for fixed-form source records.
par-affinity, Qpar-affinity	Specifies thread affinity.
parallel, Qparallel	Tells the auto-parallelizer to generate multithreaded code for loops that can be safely executed in parallel.
parallel-source-info, Qparallel-source-info	Enables or disables source location emission when OpenMP* or auto-parallelism code is generated.
par-num-threads, Qpar-num-threads	Specifies the number of threads to use in a parallel region.

par-runtime-control, Qpar-runtime-control	Generates code to perform run-time checks for loops that have symbolic loop bounds.
par-schedule, Qpar-schedule	Lets you specify a scheduling algorithm for loop iterations.
par-threshold, Qpar-threshold	Sets a threshold for the auto-parallelization of loops.
pc, Qpc	Enables control of floating-point significand precision.
p	Compiles and links for function profiling with gprof(1).
pdbfile	Lets you specify the name for a program database (PDB) file created by the linker.
pie	Determines whether the compiler generates position-independent code that will be linked into an executable.
prec-div, Qprec-div	Improves precision of floating-point divides.
prec-sqrt, Qprec-sqrt	Improves precision of square root implementations.
preprocess-only	Causes the Fortran preprocessor to send output to a file.
print-multi-lib	Prints information about where system libraries should be found.
print-sysroot	Prints the target sysroot directory that is used during compilation.
prof-data-order, Qprof-data-order	Enables or disables data ordering if profiling information is enabled.
prof-dir, Qprof-dir	Specifies a directory for profiling information output files.
prof-file, Qprof-file	Specifies an alternate file name for the profiling summary files.
prof-func-groups	Enables or disables function grouping if profiling information is enabled.
prof-func-order, Qprof-func-order	Enables or disables function ordering if profiling information is enabled.
prof-gen, Qprof-gen	Produces an instrumented object file that can be used in profile guided optimization.
prof-gen-sampling	Tells the compiler to generate debug discriminators in debug output. This aids in developing more precise sampled profiling output.
prof-hotness-threshold, Qprof-hotness-threshold	Lets you set the hotness threshold for function grouping and function ordering.
prof-src-dir, Qprof-src-dir	Determines whether directory information of the source file under compilation is considered when looking up profile data records.
prof-src-root, Qprof-src-root	Lets you use relative directory paths when looking up profile data and specifies a directory as the base.
prof-src-root-cwd, Qprof-src-root-cwd	Lets you use relative directory paths when looking up profile data and specifies the current working directory as the base.
prof-use, Qprof-use	Enables the use of profiling information during optimization.
prof-use-sampling	Lets you use data files produced by hardware profiling to produce an optimized executable.
prof-value-profiling, Qprof-value-profiling	Controls which values are value profiled.
pthread	Tells the compiler to use pthreads library for multithreading support.

qcf-protection, Qcf-protection	Enables Control-flow Enforcement Technology (CET) protection, which defends your program from certain attacks that exploit vulnerabilities. This option offers preliminary support for CET.
Qcov-dir	Specifies a directory for profiling information output files that can be used with the codecov or tselect tool.
Qcov-file	Specifies an alternate file name for the profiling summary files that can be used with the codecov or tselect tool.
Qcov-gen	Produces an instrumented object file that can be used with the codecov or tselect tool.
Qinline-dllimport	Determines whether dllimport functions are inlined.
Qinstall	Specifies the root directory where the compiler installation was performed.
Qlocation	Specifies the directory for supporting tools.
qoffload	Lets you specify the mode for offloading or tell the compiler to ignore language constructs for offloading. This is a deprecated option. There is no replacement option.
qopenmp, Qopenmp	Enables the parallelizer to generate multi-threaded code based on OpenMP* directives.
qopenmp-lib, Qopenmp-lib	Lets you specify an OpenMP* run-time library to use for linking.
qopenmp-link	Controls whether the compiler links to static or dynamic OpenMP* run-time libraries.
qopenmp-offload	Enables or disables OpenMP* offloading compilation for the TARGET directives .
qopenmp-simd, Qopenmp-simd	Enables or disables OpenMP* SIMD compilation.
qopenmp-stubs, Qopenmp-stubs	Enables compilation of OpenMP* programs in sequential mode.
qopenmp-threadprivate, Qopenmp-threadprivate	Lets you specify an OpenMP* threadprivate implementation.
qopt-args-in-regs, Qopt-args-in-regs	Determines whether calls to routines are optimized by passing arguments in registers instead of on the stack.
qopt-assume-safe-padding, Qopt-assume-safe-padding	Determines whether the compiler assumes that variables and dynamically allocated memory are padded past the end of the object.
qopt-block-factor, Qopt-block-factor	Lets you specify a loop blocking factor.
qopt-dynamic-align, Qopt-dynamic-align	Enables or disables dynamic data alignment optimizations.
Qoption	Passes options to a specified tool.
qopt-jump-tables, Qopt-jump-tables	Enables or disables generation of jump tables for switch statements.
qopt-malloc-options	Lets you specify an alternate algorithm for malloc().
qopt-matmul, Qopt-matmul	Enables or disables a compiler-generated Matrix Multiply (matmul) library call.

qopt-mem-layout-trans, Qopt-mem-layout-trans	Controls the level of memory layout transformations performed by the compiler.
qopt-multi-version-aggressive, Qopt-multi-version-aggressive	Tells the compiler to use aggressive multi-versioning to check for pointer aliasing and scalar replacement.
qopt-prefetch, Qopt-prefetch	Enables or disables prefetch insertion optimization.
qopt-prefetch-distance, Qopt-prefetch-distance	Specifies the prefetch distance to be used for compiler-generated prefetches inside loops.
qopt-prefetch-issue-excl-hint, Qopt-prefetch-issue-excl-hint	Supports the prefetchW instruction in Intel® microarchitecture code name Broadwell and later.
qopt-ra-region-strategy, Qopt-ra-region-strategy	Selects the method that the register allocator uses to partition each routine into regions.
qopt-report, Qopt-report	Tells the compiler to generate an optimization report.
qopt-report-annotate, Qopt-report-annotate	Enables the annotated source listing feature and specifies its format.
qopt-report-annotate-position, Qopt-report-annotate-position	Enables the annotated source listing feature and specifies the site where optimization messages appear in the annotated source in inlined cases of loop optimizations.
qopt-report-embed, Qopt-report-embed	Determines whether special loop information annotations will be embedded in the object file and/or the assembly file when it is generated.
qopt-report-file, Qopt-report-file	Specifies that the output for the optimization report goes to a file, stderr, or stdout.
qopt-report-filter, Qopt-report-filter	Tells the compiler to find the indicated parts of your application, and generate optimization reports for those parts of your application.
qopt-report-format, Qopt-report-format	Specifies the format for an optimization report.
qopt-report-help, Qopt-report-help	Displays the optimizer phases available for report generation and a short description of what is reported at each level.
qopt-report-names, Qopt-report-names	Specifies whether mangled or unmangled names should appear in the optimization report.
qopt-report-per-object, Qopt-report-per-object	Tells the compiler that optimization report information should be generated in a separate file for each object.
qopt-report-phase, Qopt-report-phase	Specifies one or more optimizer phases for which optimization reports are generated.
qopt-report-routine, Qopt-report-routine	Tells the compiler to generate an optimization report for each of the routines whose names contain the specified substring.
qopt-streaming-stores, Qopt-streaming-stores	Enables generation of streaming stores for optimization.
qopt-subscript-in-range, Qopt-subscript-in-range	Determines whether the compiler assumes that there are no "large" integers being used or being computed inside loops.
qopt-zmm-usage, Qopt-zmm-usage	Defines a level of zmm registers usage.

qoverride-limits, Qoverride-limits	Lets you override certain internal compiler limits that are intended to prevent excessive memory usage or compile times for very large, complex compilation units.
Qpar-adjust-stack	Tells the compiler to generate code to adjust the stack size for a fiber-based main thread.
Qpatchable-addresses	Tells the compiler to generate code such that references to statically assigned addresses can be patched.
Qsfalign	Specifies stack alignment for functions.
qsimd-honor-fp-model, Qsimd-honor-fp-model	Tells the compiler to obey the selected floating-point model when vectorizing SIMD loops.
qsimd-serialize-fp-reduction, Qsimd-serialize-fp-reduction	Tells the compiler to serialize floating-point reduction when vectorizing SIMD loops.
Quse-msasm-symbols	Tells the compiler to use a dollar sign ("$") when producing symbol names.
Qvc	Specifies compatibility with Microsoft*Visual C++* or Microsoft Visual Studio*.
rcd, Qrcd	Enables fast float-to-integer conversions. This is a deprecated option. There is no replacement option.
real-size	Specifies the default KIND for real and complex declarations, constants, functions, and intrinsics.
recursive	Tells the compiler that all routines should be compiled for possible recursive execution.
reentrancy	Tells the compiler to generate reentrant code to support a multithreaded application.
safe-cray-ptr, Qsafe-cray-ptr	Tells the compiler that Cray* pointers do not alias other variables.
save, Qsave	Causes variables to be placed in static memory.
save-temps, Qsave-temps	Tells the compiler to save intermediate files created during compilation.
scalar-rep, Qscalar-rep	Enables or disables the scalar replacement optimization done by the compiler as part of loop transformations.
S	Causes the compiler to compile to an assembly file only and not link.
shared-intel	Causes Intel-provided libraries to be linked in dynamically.
shared-libgcc	Links the GNU libgcc library dynamically.
shared	Tells the compiler to produce a dynamic shared object instead of an executable.
show	Controls the contents of the listing generated when option list is specified.
simd, Qsimd	Enables or disables compiler interpretation of SIMD directives .
sox	Tells the compiler to save the compilation options and version number in the executable file. It also lets you choose whether to include lists of certain routines .
standard-realloc-lhs	Determines whether the compiler uses the current Fortran Standard rules or the old Fortran 2003 rules when interpreting assignment statements.

standard-semantics	Determines whether the current Fortran Standard behavior of the compiler is fully implemented.
stand	Tells the compiler to issue compile-time messages for nonstandard language elements.
static-intel	Causes Intel-provided libraries to be linked in statically.
static-libgcc	Links the GNU libgcc library statically.
staticlib	Invokes the libtool command to generate static libraries.
static-libstdc++	Links the GNU libstdc++ library statically.
static	Prevents linking with shared libraries.
syntax-only	Tells the compiler to check only for correct syntax.
sysroot	Specifies the root directory where headers and libraries are located.
tcollect, Qtcollect	Inserts instrumentation probes calling the Intel® Trace Collector API.
tcollect-filter, Qtcollect-filter	Lets you enable or disable the instrumentation of specified functions. You must also specify option [Q]tcollect.
Tf	Tells the compiler to compile the file as a Fortran source file.
threads	Tells the linker to search for unresolved references in a multithreaded run-time library.
traceback	Tells the compiler to generate extra information in the object file to provide source file traceback information when a severe error occurs at run time.
T	Tells the linker to read link commands from a file.
u (Windows*)	Undefines all previously defined preprocessor values.
undef	Disables all predefined symbols .
unroll , Qunroll	Tells the compiler the maximum number of times to unroll loops.
unroll-aggressive, Qunroll-aggressive	Determines whether the compiler uses more aggressive unrolling for certain loops.
use-asm, Quse-asm	Tells the compiler to produce objects through the assembler. This is a deprecated option. There is no replacement option.
U	Undefines any definition currently in effect for the specified symbol .
vec, Qvec	Enables or disables vectorization.
vecabi, Qvecabi	Determines which vector function application binary interface (ABI) the compiler uses to create or call vector functions.
vec-guard-write, Qvec-guard-write	Tells the compiler to perform a conditional check in a vectorized loop.
vec-threshold, Qvec-threshold	Sets a threshold for the vectorization of loops.
vms	Causes the run-time system to behave like HP* Fortran on OpenVMS* Alpha systems and VAX* systems (VAX FORTRAN*).
v	Specifies that driver tool commands should be displayed and executed.
Wa	Passes options to the assembler for processing.

warn	Specifies diagnostic messages to be issued by the compiler.
watch	Tells the compiler to display certain information to the console output window.
WB	Turns a compile-time bounds check into a warning.
what	Tells the compiler to display its detailed version string.
winapp	Tells the compiler to create a graphics or Fortran Windows application and link against the most commonly used libraries.
Winline	Warns when a function that is declared as inline is not inlined.
Wl	Passes options to the linker for processing.
Wp	Passes options to the preprocessor.
wrap-margin	Provides a way to disable the right margin wrapping that occurs in Fortran list-directed output.
x, Qx	Tells the compiler which processor features it may target, including which instruction sets and optimizations it may generate.
xHost, QxHost	Tells the compiler to generate instructions for the highest instruction set available on the compilation host processor.
Xlinker	Passes a linker option directly to the linker.
X	Removes standard directories from the include file search path.
zero, Qzero	Initializes to zero variables of intrinsic type INTEGER, REAL, COMPLEX, or LOGICAL that are not yet initialized. This is a deprecated option. The replacement option is /Qinit:[no]zero or -init=[no]zero.
Zi, Z7	Tells the compiler to generate full debugging information in either an object (.obj) file or a project database (PDB) file.
Zo	Enables or disables generation of enhanced debugging information for optimized code.

Deprecated and Removed Compiler Options

This topic lists deprecated and removed compiler options and suggests replacement options, if any are available.

For more information on compiler options, see the detailed descriptions of the individual option descriptions in this section.

Deprecated Options

Occasionally, compiler options are marked as "deprecated." Deprecated options are still supported in the current release, but are planned to be unsupported in future releases.

The following two tables list options that are currently deprecated.

Note that deprecated options are not limited to these lists.

Deprecated Linux* and macOS*Options	Suggested Replacement
`-axS`	`-axSSE4.1`
`-axT`	Linux*: `-axSSSE3`

Deprecated Linux* and macOS*Options	Suggested Replacement
	macOS*: `-axSSSE3`
`-cpp`	`-fpp`
`-march=pentiumii`	None
`-march=pentiumiii`	`-march=pentium3`
`-mcpu`	`-mtune`
`-msse`	Linux* only: `-mia32`
`-rcd`	None
`-stand f15`	`-stand f18`
`-use-asm`	None
`-xS`	`-xSSE4.1`
`-xT`	Linux: `-xSSSE3` macOS*: `-xSSSE3`
`-[no]zero`	`-init=[no]zero`

Deprecated Windows* Options	Suggested Replacement
`/arch:SSE`	`/arch:IA32`
`/Ge`	`/Gs0`
`/MDs[d]`	None
`/QaxS`	`/QaxSSE4.1`
`/QaxT`	`/QaxSSSE3`
`/QIfist`	`/Qrcd`
`/Qrcd`	None
`/Qsox`	None
`/Quse-asm`	None
`/QxS`	`/QxSSE4.1`
`/QxT`	`/QxSSSE3`
`/Qzero[-]`	`/Qinit:[no]zero`
`/stand f15`	`/stand f18`
`/unroll`	`/Qunroll`

Removed Options

Some compiler options are no longer supported and have been removed. If you use one of these options, the compiler issues a warning, ignores the option, and then proceeds with compilation.

The following two tables list options that are no longer supported.

Note that removed options are not limited to these lists.

Removed Linux* and macOS*Options	Suggested Replacement
`-1`	`-f66`
`-66`	`-f66`
`-automatic`	`-auto`
`-axB`	`-axSSE2`
`-axH`	`-axSSE4.2`
`-axi`	None
`-axK`	No exact replacement; upgrade to `-msse2`
`-axM`	None
`-axN`	Linux*: `-axSSE2` macOS*: None
`-axP`	Linux: `-axSSE3` macOS*: None
`-axW`	`-msse2`
`-cm`	`-warn nousage`
`-cxxlib-gcc[=dir]`	`-cxxlib[=dir]`
`-cxxlib-icc`	None
`-dps`	`-altparam`
`-F`	`-preprocess-only` or `-P`
`-falign-stack=mode`	None; this option is only removed on macOS*
`-fp`	`-fno-omit-frame-pointer`
`-fpstkchk`	`-fp-stack-check`
`-func-groups`	`-prof-func-groups`
`-fvisibility=internal`	`-fvisibility=hidden`
`-gcc-version`	No exact replacement; use `-gcc-name`
`-guide-profile`	None
`-i-dynamic`	`-shared-intel`
`-i-static`	`-static-intel`

Removed Linux* and macOS*Options	Suggested Replacement
-inline-debug-info	-debug inline-debug-info
-ipo-obj (and -ipo_obj)	None
-Kpic, -KPIC	-fpic
-lowercase	-names lowercase
-mp	-fp-model
-nobss-init	-no-bss-init
-no-standard-semantics	No exact replacement; negate specific options separately
-nus	-assume nounderscore
-Ob	-inline-level
-onetrip	-f66
-openmp	-qopenmp
-openmp-lib	-qopenmp-lib
-openmp-lib legacy	None
-openmp-link and -qopenmp-link	None
-openmpP	-qopenmp
-openmp-profile	None
-openmp-report	-qopt-report-phase=openmp
-openmpS	-qopenmp-stubs
-openmp-simd	-qopenmp-simd
-openmp-stubs	-qopenmp-stubs
-openmp-threadprivate	-qopenmp-threadprivate
-opt-args-in-regs	-qopt-args-in-regs
-opt-assume-safe-padding	-qopt-assume-safe-padding
-opt-block-factor	-qopt-block-factor
-opt-dynamic-align	-qopt-dynamic-align
-opt-gather-scatter-unroll	None
-opt-jump-tables	-qopt-jump-tables
-opt-malloc-options	-qopt-malloc-options
-opt-matmul	-qopt-matmul

Removed Linux* and macOS*Options	Suggested Replacement
-opt-mem-layout-trans	-qopt-mem-layout-trans
-opt-multi-version-aggressive	-qopt-multi-version-aggressive
-opt-prefetch	-qopt-prefetch
-opt-prefetch-distance	-qopt-prefetch-distance
-opt-ra-region-strategy	-qopt-ra-region-strategy
-opt-report	-qopt-report
-opt-report-embed	-qopt-report-embed
-opt-report-file	-qopt-report-file
-opt-report-filter	-qopt-report-filter
-opt-report-format	-qopt-report-format
-opt-report-help	-qopt-report-help
-opt-report-level	-qopt-report
-opt-report-per-object	-qopt-report-per-object
-opt-report-phase	-qopt-report-phase
-opt-report-routine	-qopt-report-routine
-opt-streaming-cache-evict	None
-opt-streaming-stores	-qopt-streaming-stores
-opt-subscript-in-range	-qopt-subscript-in-range
-par-report	-qopt-report-phase=par
-prefetch	-qopt-prefetch
-prof-format-32	None
-prof-gen-sampling	None
-prof-genx	-prof-gen=srcpos
-profile-functions	None
-profile-loops	None
-profile-loops-report	None
-qoffload-arch	None
-qoffload-attribute-target	None
-qoffload-option	None
-qopenmp-report	-qopt-report-phase=openmp

Removed Linux* and macOS*Options	Suggested Replacement
-qopenmp-task	None
-qp	-p
-rct	None
-shared-libcxa	-shared-libgcc
-ssp	None
-static-libcxa	-static-libgcc
-syntax	-syntax-only or -fsyntax-only
-tcheck	None
-tpp1	None
-tpp2	-mtune=itanium2
-tpp5	None
-tpp6	None
-tpp7	-mtune=pentium4
-tprofile	None
-tune	-x<code>
-uppercase	-names uppercase
-us	-assume underscore
-vec-report	-qopt-report-phase=vec
-xB	-xSSE2
-xi	None
-xK	No exact replacement; upgrade to -msse2
-xM	None
-xN	Linux: -xSSE2 macOS*: None
-xO	-msse3
-xP	Linux: -xSSE3 macOS*: None
-xSSE3_ATOM	-xATOM_SSSE3
-xSSSE3_ATOM	-xATOM_SSSE3
-xW	-msse2

Removed Windows* Options	Suggested Replacement
/1	/f66
/4ccD (and /4ccd)	None
/4Nb	/check:none
/4Yb	/check:all
/architecture	/arch
/asmattr:none, /noasmattr	/FA
/asmattr:machine	/FAc
/asmattr:source	/FAs
/asmattr:all	/FAcs
/asmfile	/Fa
/automatic	/auto
/cm	/warn:nousage
/debug:parallel	None
/debug:partial	None
/Fm	/map
/G1	None
/G5	None
/G6 (or /GB)	None
/G7	None
/Gf	/GF
/ML[d]	Upgrade to /MT[d]
/Og	/O1, /O2, or /O3
/Op	/fltconsistency
/optimize:0, /nooptimize	/Od
/optimize:1, /optimize:2	/O1
/optimize:3, /optimize:4	/O2
/optimize:5	/O3
/QaxB	/QaxSSE2
/QaxH	/QaxSSE4.2
/Qaxi	None

Removed Windows* Options	Suggested Replacement
/QaxK	Upgrade to /arch:SSE2
/QaxM	None
/QaxN	/QaxSSE2
/QaxP	/QaxSSE3
/QaxW	/arch:SSE2
/Qcpp	/fpp
/Qdps	/altparam
/Qextend-source	/extend-source
/Qfpp[0 | 1 | 2 | 3]	/fpp
/Qfpstkchk	/Qfp-stack-check
/Qguide-profile	None
/Qinline-debug-info	/debug:inline-debug-info
/Qipo-obj (and /Qipo_obj)	None
/Qlowercase	/names:lowercase
/Qonetrip	/f66
/Qopenmp-lib:legacy	None
/Qopenmp-link	None
/Qopenmp-profile	None
/Qopenmp-report	/Qopt-report-phase:openmp
/Qopt-report-level	/Qopt-report
/Qpar-report	/Qopt-report-phase:par
/Qprefetch	/Qopt-prefetch
/Qprof-format-32	None
/Qprof-gen-sampling	None
/Qprof-genx	/Qprof-gen=srcpos
/Qprofile-functions	None
/Qprofile-loops	None
/Qprofile-loops-report	None
/Qrct	None
/Qssp	None

Removed Windows* Options	Suggested Replacement
/Qtprofile	None
/Qtcheck	None
/Quppercase	/names:uppercase
/Quse-vcdebug	None
/Qvc11	None
/Qvc10	
/Qvc9 and earlier	
/Qvec-report	/Qopt-report-phase:vec
/Qvms	/vms
/QxB	/QxSSE2
/Qxi	None
/QxK	Upgrade to /arch:SSE2
/QxM	None
/QxN	/QxSSE2
/QxO	/arch:SSE3
/QxP	/QxSSE3
/QxSSE3_ATOM	/QxATOM_SSSE3
/QxSSSE3_ATOM	/QxATOM_SSSE3
/QxW	/arch:SSE2
/source	/Tf
/standard-semantics-	No exact replacement; negate specific options separately
/tune	/Qx<code>
/unix	None
/us	/assume:underscore
/w90, /w95	None
/Zd	/debug:minimal

Optimization Notice
dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice. Notice revision #20110804

Ways to Display Certain Option Information

This section describes how you can get general information about compiler options on the command line.

Displaying General Option Information From the Command Line

To display a list of all available compiler options, specify option `help` on the command line.

To display functional groupings of compiler options, specify a functional category for option `help`. For example, to display a list of options that affect diagnostic messages, enter one of the following commands:

```
-help diagnostics     ! Linux and macOS*systems
```

```
/help diagnostics     ! Windows systems
```

For details on other categories you can specify, see help.

Compiler Option Details

This section contains the full details about compiler options, including descriptions of each compiler option.

In this section compiler options are listed within their categories. To see an alphabetical list of compiler options, see Alphabetical List of Compiler Options .

General Rules for Compiler Options

This section describes general rules for compiler options and it contains information about how we refer to compiler option names in descriptions.

General Rules for Compiler Options

You cannot combine options with a single dash (Linux* and macOS*) or slash (Windows*). For example:

- On Linux* and macOS* systems: This is incorrect: `-Ec`; this is correct: `-E -c`
- On Windows* systems: This is incorrect: `/Ec`; this is correct: `/E /c`

All Linux* and macOS* compiler options are case sensitive. Many Windows* options are case sensitive. Some options have different meanings depending on their case; for example, option "c" prevents linking, but option "C" checks for certain conditions at run time.

Options specified on the command line apply to all files named on the command line.

Options can take arguments in the form of file names, strings, letters, or numbers. If a string includes spaces, the string must be enclosed in quotation marks. For example:

- On Linux* and macOS* systems, `-dynamic-linker` *mylink* (file name) or `-U`*macro3* (string)
- On Windows* systems, `/Famyfile.s` (file name) or `/V`*"version 5.0"* (string)

Compiler options can appear in any order.

On Windows* systems, all compiler options must precede `/link` options, if any, on the command line.

Unless you specify certain options, the command line will both compile and link the files you specify.

You can abbreviate some option names, entering as many characters as are needed to uniquely identify the option.

Certain options accept one or more keyword arguments following the option name. For example, the `ax` option accepts several keywords.

To specify multiple keywords, you typically specify the option multiple times.

NOTE
On Windows* systems, you can sometimes use a comma to separate keywords. For example, the following is valid:

```
ifort /warn:usage,declarations test.f90
```

On these systems, you can use an equals sign (=) instead of the colon:

```
ifort /warn=usage,declarations test.f90
```

Compiler options remain in effect for the whole compilation unless overridden by a compiler directive.

To disable an option, specify the negative form of the option.

On Windows* systems, you can also disable one or more optimization options by specifying option `/Od` last on the command line.

NOTE
On Windows* systems, the `/Od` option is part of a mutually-exclusive group of options that includes `/Od`, `/O1`, `/O2`, `/O3`, and `/Ox`. The last of any of these options specified on the command line will override the previous options from this group.

If there are enabling and disabling versions of an option on the command line, the last one on the command line takes precedence.

How We Refer to Compiler Option Names in Descriptions

The following conventions are used as shortcuts when referencing compiler option names in descriptions:

- Many options have names that are the same on Linux*, macOS*, and Windows*, except that the Windows form starts with an initial / and the Linux and macOS* form starts with an initial -. Within text, such option names are shown without the initial character; for example, `check`.
- Many options have names that are the same on Linux*, macOS*, and Windows*, except that the Windows form starts with an initial Q. Within text, such option names are shown as `[Q]option-name`.

  For example, if you see a reference to `[Q]ipo`, the Linux* and macOS* form of the option is `-ipo` and the Windows form of the option is `/Qipo`.
- Several compiler options have similar names except that the Linux* and macOS* forms start with an initial q and the Windows form starts with an initial Q. Within text, such option names are shown as `[q or Q]option-name`.

  For example, if you see a reference to `[q or Q]opt-report`, the Linux* and macOS* form of the option is `-qopt-report` and the Windows form of the option is `/Qopt-report`.

Compiler option names that are more dissimilar are shown in full.

What Appears in the Compiler Option Descriptions

This section contains details about what appears in the option descriptions.

Following sections include individual descriptions of all the current compiler options. The option descriptions are arranged by functional category. Within each category, the option names are listed in alphabetical order.

Each option description contains the following information:

- The primary name for the option and a short description of the option.
- Architecture Restrictions
  This section only appears if there is a known architecture restriction for the option.

  Restrictions may appear for any of the following architectures:

  - IA-32 architecture
  - Intel® 64 architecture

  Certain operating systems are not available on all the above architectures. For the latest information, please check your Release Notes.
- Syntax
  This shows the syntax on Linux* and macOS* systems and the syntax on Windows* systems. If the option has no syntax on one of these systems, that is, the option is not valid on a particular operating system, it will specify "None".
- Arguments
  This shows any arguments (parameters) that are related to the option. If the option has no arguments, it will specify "None".
- Default
  This shows the default setting for the option.
- Description
  This shows the full description of the option. It may also include further information on any applicable arguments.
- IDE Equivalent
  This shows information related to the integrated development environment (IDE) Property Pages on Linux*, macOS*, and Windows* systems. It shows on which Property Page the option appears, and under what category it's listed. The Windows* IDE is Microsoft* Visual Studio* .NET; the Linux* IDE is Eclipse*; the macOS* IDE is Xcode*. If the option has no IDE equivalent, it will specify "None". Note that in this release, there is no IDE support for Fortran on Linux*.
- Alternate Options
  This lists any options that are synonyms for the described option. If there are no alternate option names, it will show "None".
  Some of the alternate option names are deprecated and may be removed in future releases.
  Many options have an older spelling where underscores ("_") instead of hyphens ("-") connect the main option names. The older spelling is a valid alternate option name.

Some option descriptions may also have the following:

- Example
  This shows a short example that includes the option
- See Also
  This shows where you can get further information on the option or related options.

Offload Options (Linux* only)

qoffload

Lets you specify the mode for offloading or tell the compiler to ignore language constructs for offloading. This is a deprecated option. There is no replacement option.

Syntax

Linux OS:

`-qoffload[=keyword]`

`-qno-offload`

macOS:

None

Windows OS:

None

Arguments

keyword Specifies the mode for offloading or it disables offloading. Possible values are:

`none` Tells the compiler to ignore language constructs for offloading. Warnings are issued by the compiler. This is equivalent to the negative form of the option.

`mandatory` Specifies that offloading is mandatory (required). If the target is not available, one of the following occurs:

- If no STATUS clause is specified for the OFFLOAD directive, the program fails with an error message.
- If the STATUS clause is specified, the program continues execution on the CPU.

`optional` Specifies that offloading is optional (requested). If the target is not available, the program is executed on the CPU, not the target.

Default

mandatory The compiler recognizes language constructs for offloading if they are specified. If option `-qoffload` is specified with no *keyword*, the default is `mandatory`.

Description

This option lets you specify the mode for offloading or tell the compiler to ignore language constructs for offloading.

Option `-q[no-]offload` is the replacement option for `-[no-]offload`, which is deprecated.

If no `-qoffload` option appears on the command line, then OFFLOAD directives are processed and:

- The MANDATORY or OPTIONAL clauses are obeyed if present
- If no MANDATORY or OPTIONAL clause is present, the offload is mandatory

If `-qoffload=none` or `-qno-offload` appears on the command line, then OFFLOAD directives are ignored:

However, OpenMP* directives for processor control (for example, !$OMP TARGET) are recognized if the `[q or Q]openmp` option is specified, regardless of whether or not OFFLOAD directives are recognized or ignored.

If *keyword* `mandatory` or `optional` appears for `-qoffload`, then OFFLOAD directives are processed and:

- The MANDATORY or OPTIONAL clauses are obeyed, regardless of the `-qoffload` *keyword* specified.
- If no MANDATORY or OPTIONAL clause is present, then the `-qoffload` *keyword* is obeyed.

If the STATUS clause is specified for an OFFLOAD directive, it affects run-time behavior.

IDE Equivalent

None

Alternate Options

None

Supported Environment Variables

Optimization Options

falias, Oa

Specifies whether or not a procedure call may have hidden aliases of local variables not supplied as actual arguments.

Syntax

Linux OS and macOS:

`-falias`

`-fno-alias`

Windows OS:

`/Oa`

`/Oa-`

Arguments

None

Default

`-fno-alias` or `/Oa`	Procedure calls do not alias local variables.

Description

This option specifies whether or not the compiler can assume that during a procedure call, local variables in the caller that are not present in the actual argument list and not visible by host association, are not referenced or redefined due to hidden aliasing. The Fortran standard generally prohibits such aliasing.

If you specify `-falias` (Linux* and macOS*) or `/Oa-` (Windows*), aliasing during a procedure call is assumed; this can possibly affect performance.

If you specify `-fno-alias` or `/Oa` (the default), aliasing during a procedure call is not assumed.

IDE Equivalent

None

Alternate Options

None

`ffnalias` compiler option

fast

Maximizes speed across the entire program.

Syntax

Linux OS:

`-fast`

macOS:

`-fast`

Windows OS:

`/fast`

Arguments

None

Default

OFF The optimizations that maximize speed are not enabled.

Description

This option maximizes speed across the entire program.

It sets the following options:

- On macOS* systems: `-ipo`, `-mdynamic-no-pic`,`-O3`, `-no-prec-div`,`-fp-model fast=2`, and `-xHost`
- On Windows* systems: `/O3`, `/Qipo`, `/Qprec-div-`, `/fp:fast=2`, and `/QxHost`
- On Linux* systems: `-ipo`, `-O3`, `-no-prec-div`,`-static`, `-fp-model fast=2`, and `-xHost`

When option `fast` is specified, you can override the `[Q]xHost` option setting by specifying a different processor-specific `[Q]x` option on the command line. However, the last option specified on the command line takes precedence.

For example:

- On Linux* systems, if you specify option `-fast -xSSE3`, option `-xSSE3` takes effect. However, if you specify `-xSSE3 -fast`, option `-xHost` takes effect.
- On Windows* systems, if you specify option `/fast /QxSSE3`, option`/QxSSE3` takes effect. However, if you specify `/QxSSE3 /fast`, option `/QxHost` takes effect.

For implications on non-Intel processors, refer to the `[Q]xHost` documentation.

> **NOTE**
> Option `fast` sets some aggressive optimizations that may not be appropriate for all applications. The resulting executable may not run on processor types different from the one on which you compile. You should make sure that you understand the individual optimization options that are enabled by option `fast`.

Optimization Notice
Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain

Optimization Notice
optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice. Notice revision #20110804

compiler option

ffnalias, Ow

Determines whether aliasing is assumed within functions.

Syntax

Linux OS and macOS:

`-ffnalias`

`-fno-fnalias`

Windows OS:

`/Ow`

`/Ow-`

Arguments

None

Default

`-ffnalias` or `/Ow`	Aliasing is assumed within functions.

Description

This option determines whether aliasing is assumed within functions.

If you specify `-fno-fnalias` or `/Ow-`, aliasing is not assumed within functions, but it is assumed across calls.

If you specify `-ffnalias` or `/Ow`, aliasing is assumed within functions.

IDE Equivalent

None

Alternate Options

None

See Also

falias compiler option

foptimize-sibling-calls

Determines whether the compiler optimizes tail recursive calls.

Syntax

Linux OS:

`-foptimize-sibling-calls`

`-fno-optimize-sibling-calls`

macOS:

`-foptimize-sibling-calls`

`-fno-optimize-sibling-calls`

Windows OS:

`None`

Arguments

None

Default

`-foptimize-sibling-calls` The compiler optimizes tail recursive calls.

Description

This option determines whether the compiler optimizes tail recursive calls. It enables conversion of tail recursion into loops.

If you do not want to optimize tail recursive calls, specify `-fno-optimize-sibling-calls`.

Tail recursion is a special form of recursion that doesn't use stack space. In tail recursion, a recursive call is converted to a GOTO statement that returns to the beginning of the function. In this case, the return value of the recursive call is only used to be returned. It is not used in another expression. The recursive function is converted into a loop, which prevents modification of the stack space used.

IDE Equivalent

None

Alternate Options

None

fprotect-parens, Qprotect-parens

Determines whether the optimizer honors parentheses when floating-point expressions are evaluated.

Syntax

Linux OS and macOS:

`-fprotect-parens`

`-fno-protect-parens`

Windows OS:

`/Qprotect-parens`

`/Qprotect-parens-`

Arguments

None

Default

`-fno-protect-parens` or `/Qprotect-parens-`	Parentheses are ignored when determining the order of expression evaluation.

Description

This option determines whether the optimizer honors parentheses when determining the order of floating-point expression evaluation.

When option `-fprotect-parens` (Linux* and macOS*) or `/Qprotect-parens` (Windows*) is specified, the optimizer will maintain the order of evaluation imposed by parentheses in the code.

When option `-fno-protect-parens` (Linux* and macOS*) or `/Qprotect-parens-` (Windows*) is specified, the optimizer may reorder floating-point expressions without regard for parentheses if it produces faster executing code.

IDE Equivalent

None

Alternate Options

Linux and macOS*: `-assume protect_parens`

Windows: `/assume:protect_parens`

Example

Consider the following expression:

```
A+(B+C)
```

By default, the parentheses are ignored and the compiler is free to re-order the floating-point operations based on the optimization level, the setting of option `-fp-model` (Linux* and macOS*) or `/fp` (Windows*), etc. to produce faster code. Code that is sensitive to the order of operations may produce different results (such as with some floating-point computations).

However, if `-fprotect-parens` (Linux* and macOS*) or `/Qprotect-parens` (Windows*) is specified, parentheses around floating-point expressions (including complex floating-point and decimal floating-point) are honored and the expression will be interpreted following the normal precedence rules, that is, B+C will be computed first and then added to A.

This may produce slower code than when parentheses are ignored. If floating-point sensitivity is a specific concern, you should use option `-fp-model precise` (Linux* and macOS*) or `/fp:precise` (Windows*) to ensure precision because it controls all optimizations that may affect precision.

GF

Enables read-only string-pooling optimization.

Syntax

Linux OS:

`None`

macOS:

`None`

Windows OS:

`/GF`

Arguments

None

Default

OFF Read/write string-pooling optimization is enabled.

Description

This option enables read only string-pooling optimization.

IDE Equivalent

None

Alternate Options

None

nolib-inline

Disables inline expansion of standard library or intrinsic functions.

Syntax

Linux OS:

`-nolib-inline`

macOS:

`-nolib-inline`

Windows OS:

None

Arguments

None

Default

OFF The compiler inlines many standard library and intrinsic functions.

Description

This option disables inline expansion of standard library or intrinsic functions. It prevents the unexpected results that can arise from inline expansion of these functions.

IDE Equivalent

None

Alternate Options

None

O

Specifies the code optimization for applications.

Syntax

Linux OS:

`-O[n]`

macOS:

`-O[n]`

Windows OS:

`/O[n]`

Arguments

n	Is the optimization level. Possible values are 1, 2, or 3. On Linux* and macOS* systems, you can also specify 0.

Default

`O2` Optimizes for code speed. This default may change depending on which other compiler options are specified. For details, see below.

Description

This option specifies the code optimization for applications.

Option	Description
`O` (Linux* and macOS*)	This is the same as specifying `O2`.
`O0` (Linux and macOS*)	Disables all optimizations.

Option	Description
	This option may set other options. This is determined by the compiler, depending on which operating system and architecture you are using. The options that are set may change from release to release. This option causes certain `warn` options to be ignored. This is the default if you specify option `-debug` (with no keyword).
`O1`	Enables optimizations for speed and disables some optimizations that increase code size and affect speed. To limit code size, this option: • Enables global optimization; this includes data-flow analysis, code motion, strength reduction and test replacement, split-lifetime analysis, and instruction scheduling. This option may set other options. This is determined by the compiler, depending on which operating system and architecture you are using. The options that are set may change from release to release. The `O1` option may improve performance for applications with very large code size, many branches, and execution time not dominated by code within loops.

`O2`	Enables optimizations for speed. This is the generally recommended optimization level.
	Vectorization is enabled at `O2` and higher levels.
	
	On systems using IA-32 architecture: Some basic loop optimizations such as Distribution, Predicate Opt, Interchange, multi-versioning, and scalar replacements are performed.
	
	This option also enables:
	• Inlining of intrinsics
	• Intra-file interprocedural optimization, which includes:
	  • inlining
	  • constant propagation
	  • forward substitution
	  • routine attribute propagation
	  • variable address-taken analysis
	  • dead static function elimination
	  • removal of unreferenced variables
	• The following capabilities for performance gain:
	  • constant propagation
	  • copy propagation
	  • dead-code elimination
	  • global register allocation
	  • global instruction scheduling and control speculation
	  • loop unrolling
	  • optimized code selection
	  • partial redundancy elimination
	  • strength reduction/induction variable simplification
	  • variable renaming
	  • exception handling optimizations

Option	Description
	• tail recursions • peephole optimizations • structure assignment lowering and optimizations • dead store elimination This option may set other options, especially options that optimize for code speed. This is determined by the compiler, depending on which operating system and architecture you are using. The options that are set may change from release to release. On Windows* systems, this option is the same as the `Ox` option. On Linux* and macOS* systems, if `-g` is specified, `O2` is turned off and `O0` is the default unless `O2` (or `O1` or `O3`) is explicitly specified in the command line together with `-g`. On Linux systems, the `-debug inline-debug-info` option will be enabled by default if you compile with optimizations (option `-O2` or higher) and debugging is enabled (option `-g`). Many routines in the shared libraries are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.
`O3`	Performs `O2` optimizations and enables more aggressive loop transformations such as Fusion, Block-Unroll-and-Jam, and collapsing IF statements. This option may set other options. This is determined by the compiler, depending on which operating system and architecture you are using. The options that are set may change from release to release. When `O3` is used with options `-ax` or `-x` (Linux) or with options `/Qax` or `/Qx` (Windows), the compiler performs more aggressive data dependency analysis than for `O2`, which may result in longer compilation times. The `O3` optimizations may not cause higher performance unless loop and memory access transformations take place. The optimizations may slow down code in some cases compared to `O2` optimizations. The `O3` option is recommended for applications that have loops that heavily use floating-point calculations and process large data sets. Many routines in the shared libraries are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

The last `O` option specified on the command line takes precedence over any others.

IDE Equivalent

Visual Studio: **General > Optimization** (`/Od`, `/O1`, `/O2`, `/O3`, `/fast`)

Optimization > Optimization (`/Od`, `/O1`, `/O2`, `/O3`, `/fast`)

Eclipse: None

Xcode: **General > Optimization Level** (`-O`)

fast compiler option

Od

Disables all optimizations.

Syntax

Linux OS:

None

macOS:

None

Windows OS:

/Od

Arguments

None

Default

OFF	The compiler performs default optimizations.

Description

This option disables all optimizations. It can be used for selective optimizations, such as a combination of /Od and /Ob1 (disables all optimizations, but enables inlining).

This option also causes certain /warn options to be ignored.

On IA-32 architecture, this option sets the /Oy- option.

IDE Equivalent

Visual Studio: **Optimization > Optimization**

Eclipse: None

Xcode: None

Alternate Options

Linux and macOS*: -O0

Windows: /optimize:0

O compiler option (see O0)

Ofast

Sets certain aggressive options to improve the speed of your application.

Syntax

Linux OS:

`-Ofast`

macOS:

`-Ofast`

Windows OS:

`None`

Arguments

None

Default

OFF The aggressive optimizations that improve speed are not enabled.

Description

This option improves the speed of your application.

It sets compiler options `-O3`, `-no-prec-div`, and -fp-model fast=2.

On Linux* systems, this option is provided for compatibility with gcc.

IDE Equivalent

None

Alternate Options

None

Os

Enables optimizations that do not increase code size; it produces smaller code size than O2.

Syntax

Linux OS:

`-Os`

macOS:

`-Os`

Windows OS:

`/Os`

Arguments

None

Default

OFF Optimizations are made for code speed. However, if `O1` is specified, `Os` is the default.

Description

This option enables optimizations that do not increase code size; it produces smaller code size than `O2`. It disables some optimizations that increase code size for a small speed benefit.

This option tells the compiler to favor transformations that reduce code size over transformations that produce maximum performance.

IDE Equivalent

Code Generation Options

arch

Tells the compiler which features it may target, including which instruction sets it may generate.

Syntax

Linux OS and macOS:

`-arch` *code*

Windows OS:

`/arch:`*code*

Arguments

code

Indicates to the compiler a feature set that it may target, including which instruction sets it may generate. Many of the following descriptions refer to Intel® Streaming SIMD Extensions (Intel® SSE) and Supplemental Streaming SIMD Extensions (SSSE). Possible values are:

`AMBERLAKE`
`BROADWELL`
`CANNONLAKE`
`CASCADELAKE`
`COFFEELAKE`
`GOLDMONT`
`GOLDMONT-PLUS`
`HASWELL`
`ICELAKE-CLIENT` (or `ICELAKE`)
`ICELAKE-SERVER`
`IVYBRIDGE`
`KABYLAKE`
`KNL`
	May generate instructions for processors that support the specified Intel® processor or microarchitecture code name.
	
	Keyword `ICELAKE` is deprecated and may be removed in a future release.

KNM SANDYBRIDGE SILVERMONT SKYLAKE SKYLAKE-AVX512 TREMONT WHISKEYLAKE	
CORE-AVX2	May generate Intel® Advanced Vector Extensions 2 (Intel® AVX2), Intel® AVX, SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
CORE-AVX-I	May generate the RDRND instruction, Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
AVX	May generate Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
SSE4.2	May generate Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
SSE4.1	May generate Intel® SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
SSSE3	May generate SSSE3 instructions and Intel® SSE3, SSE2, and SSE instructions.
SSE3	May generate Intel® SSE3, SSE2, and SSE instructions.
SSE2	May generate Intel® SSE2 and SSE instructions. This value is only available on Linux* and Windows* systems.
SSE	This option has been deprecated; it is now the same as specifying IA32.
IA32	Generates x86/x87 generic code that is compatible with IA-32 architecture. Disables any default extended instruction settings, and any previously set extended instruction settings. It also disables all feature-specific optimizations and instructions. This value is only available on Linux* and Windows* systems using IA-32 architecture.

Default

Windows and Linux systems: `SSE2` macOS* systems: `SSSE3`	For more information on the default values, see Arguments above.

Description

This option tells the compiler which features it may target, including which instruction sets it may generate.

Code generated with these options should execute on any compatible, non-Intel processor with support for the corresponding instruction set.

Options `/arch` and `/Qx` are mutually exclusive. If both are specified, the compiler uses the last one specified and generates a warning.

If you specify both the `/Qax` and `/arch` options, the compiler will not generate Intel-specific instructions.

For compatibility with Compaq* Visual Fortran, the compiler allows the following keyword values. However, you should use the suggested replacements.

Compatibility Value	Suggested Replacement on Linux* and Windows*
`pn1`	`-mia32` or `/arch:IA32`
`pn2`	`-mia32` or `/arch:IA32`
`pn3`	`-mia32` or `/arch:IA32`
`pn4`	`-msse2` or `/arch:SSE2`

IDE Equivalent

Visual Studio: **Code Generation > Enable Enhanced Instruction Set**

ax, Qax

Tells the compiler to generate multiple, feature-specific auto-dispatch code paths for Intel® processors if there is a performance benefit.

Syntax

Linux OS:

`-ax`*code*

macOS:

`-ax`*code*

Windows OS:

`/Qax`*code*

Arguments

code

Indicates to the compiler a feature set that it may target, including which instruction sets it may generate. The following descriptions refer to Intel® Streaming SIMD Extensions (Intel® SSE) and Supplemental Streaming SIMD Extensions (SSSE). Possible values are:

`AMBERLAKE`
`BROADWELL`
`CANNONLAKE`
`CASCADELAKE`
`COFFEELAKE`
`GOLDMONT`
`GOLDMONT-PLUS`
`HASWELL`
`ICELAKE-CLIENT` (or `ICELAKE`)
`ICELAKE-SERVER`
`IVYBRIDGE`
`KABYLAKE`
`KNL`
`KNM`
`SANDYBRIDGE`
`SILVERMONT`
`SKYLAKE`
`SKYLAKE-AVX512`
`TREMONT`
`WHISKEYLAKE`
	May generate instructions for processors that support the specified Intel® processor or microarchitecture code name.
	Keywords `KNL` and `SILVERMONT` are only available on Windows* and Linux* systems.
	Keyword `ICELAKE` is deprecated and may be removed in a future release.

`COMMON-AVX512`	May generate Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Foundation instructions, Intel® AVX-512 Conflict Detection instructions, as well as the instructions enabled with CORE-AVX2.

`CORE-AVX512`	May generate Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Foundation instructions, Intel® AVX-512 Conflict Detection instructions, Intel® AVX-512 Doubleword and Quadword instructions, Intel® AVX-512 Byte and Word instructions and Intel® AVX-512 Vector Length extensions, as well as the instructions enabled with CORE-AVX2.
`CORE-AVX2`	May generate Intel® Advanced Vector Extensions 2 (Intel® AVX2), Intel® AVX, SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors.
`CORE-AVX-I`	May generate the RDRND instruction, Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors.
`AVX`	May generate Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors.
`SSE4.2`	May generate Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel processors.
`SSE4.1`	May generate Intel® SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors.
`SSSE3`	May generate SSSE3 instructions and Intel® SSE3, SSE2, and SSE instructions for Intel® processors. For macOS* systems, this value is only supported on Intel® 64 architecture. This replaces value T, which is deprecated.
`SSE3`	May generate Intel® SSE3, SSE2, and SSE instructions for Intel® processors. This value is not available on macOS* systems.
`SSE2`	May generate Intel® SSE2 and SSE instructions for Intel® processors. This value is not available on macOS* systems.

Default

OFF No auto-dispatch code is generated. Feature-specific code is generated and is controlled by the setting of the following compiler options:

- Linux*: `-m` and `-x`
- Windows*: `/arch` and `/Qx`
- macOS*: `-x`

Description

This option tells the compiler to generate multiple, feature-specific auto-dispatch code paths for Intel® processors if there is a performance benefit. It also generates a baseline code path. The Intel feature-specific auto-dispatch path is usually more optimized than the baseline path. Other options, such as `O3`, control how much optimization is performed on the baseline path.

The baseline code path is determined by the architecture specified by options `-m` or `-x` (Linux* and macOS*) or options `/arch` or `/Qx` (Windows*). While there are defaults for the `[Q]x` option that depend on the operating system being used, you can specify an architecture and optimization level for the baseline code that is higher or lower than the default. The specified architecture becomes the effective minimum architecture for the baseline code path.

If you specify both the `[Q]ax` and `[Q]x` options, the baseline code will only execute on Intel® processors compatible with the setting specified for the `[Q]x`.

If you specify both the `-ax` and `-m` options (Linux and macOS*) or the `/Qax` and `/arch` options (Windows), the baseline code will execute on non-Intel processors compatible with the setting specified for the `-m` or `/arch` option.

If you specify both the `-ax` and `-march` options (Linux and macOS*), or the `/Qax` and `/arch` options (Windows), the compiler will not generate Intel-specific instructions.

The `[Q]ax` option tells the compiler to find opportunities to generate separate versions of functions that take advantage of features of the specified instruction features.

If the compiler finds such an opportunity, it first checks whether generating a feature-specific version of a function is likely to result in a performance gain. If this is the case, the compiler generates both a feature-specific version of a function and a baseline version of the function. At run time, one of the versions is chosen to execute, depending on the Intel® processor in use. In this way, the program can benefit from performance gains on more advanced Intel processors, while still working properly on older processors and non-Intel processors. A non-Intel processor always executes the baseline code path.

You can use more than one of the feature values by combining them. For example, you can specify `-axSSE4.1,SSSE3` (Linux and macOS*) or `/QaxSSE4.1,SSSE3` (Windows). You cannot combine the old style, deprecated options and the new options. For example, you cannot specify `-axSSE4.1,T` (Linux and macOS*) or `/QaxSSE4.1,T` (Windows).

Optimization Notice
Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice. Notice revision #20110804

fasynchronous-unwind-tables

Determines whether unwind information is precise at an instruction boundary or at a call boundary.

Syntax

Linux OS:

```
-fasynchronous-unwind-tables
-fno-asynchronous-unwind-tables
```

macOS:

```
-fasynchronous-unwind-tables
-fno-asynchronous-unwind-tables
```

Windows OS:

```
None
```

Arguments

None

Default

Intel® 64 architecture: `-fasynchronous-unwind-tables`	The unwind table generated is precise at an instruction boundary, enabling accurate unwinding at any instruction.
IA-32 architecture (Linux* only): `-fno-asynchronous-unwind-tables`	The unwind table generated is precise at call boundaries only.

Description

This option determines whether unwind information is precise at an instruction boundary or at a call boundary. The compiler generates an unwind table in DWARF2 or DWARF3 format, depending on which format is supported on your system.

If `-fno-asynchronous-unwind-tables` is specified, the unwind table is precise at call boundaries only. In this case, the compiler will avoid creating unwind tables for routines such as the following:

- A C++ routine that does not declare objects with destructors and does not contain calls to routines that might throw an exception.
- A C/C++ or Fortran routine compiled without `-fexceptions`, and on Intel® 64 architecture, without `-traceback`.
- A C/C++ or Fortran routine compiled with `-fexceptions` that does not contain calls to routines that might throw an exception.

IDE Equivalent

None

Alternate Options

None

See Also

fexceptions compiler option

fexceptions

Enables exception handling table generation.

Syntax

Linux OS:

`-fexceptions`

`-fno-exceptions`

macOS:

`-fexceptions`

`-fno-exceptions`

Windows OS:

`None`

Arguments

None

Default

-fno-exceptions	Exception handling table generation is disabled.

Description

This option enables C++ exception handling table generation, preventing Fortran routines in mixed-language applications from interfering with exception handling between C++ routines. The `-fno-exceptions` option disables C++ exception handling table generation, resulting in smaller code. When this option is used, any use of C++ exception handling constructs (such as try blocks and throw statements) when a Fortran routine is in the call chain will produce an error.

IDE Equivalent

None

Alternate Options

None

fomit-frame-pointer, Oy

Determines whether EBP is used as a general-purpose register in optimizations.

Architecture Restrictions

Option `/Oy[-]` is only available on IA-32 architecture

Syntax

Linux OS:

`-fomit-frame-pointer`

`-fno-omit-frame-pointer`

macOS:

`-fomit-frame-pointer`

`-fno-omit-frame-pointer`

Windows OS:

`/Oy`

`/Oy-`

Arguments

None

Default

`-fomit-frame-pointer` or `/Oy`	EBP is used as a general-purpose register in optimizations. However, on Linux* and macOS* systems, the default is `-fno-omit-frame-pointer` if option `-O0` or `-g` is specified. On Windows* systems, the default is `/Oy-` if option `/Od` is specified.

Description

These options determine whether EBP is used as a general-purpose register in optimizations. Options `-fomit-frame-pointer` and `/Oy` allow this use. Options `-fno-omit-frame-pointer` and `/Oy-` disallow it.

Some debuggers expect EBP to be used as a stack frame pointer, and cannot produce a stack backtrace unless this is so. The `-fno-omit-frame-pointer` and `/Oy-` options direct the compiler to generate code that maintains and uses EBP as a stack frame pointer for all functions so that a debugger can still produce a stack backtrace without doing the following:

- For `-fno-omit-frame-pointer`: turning off optimizations with `-O0`
- For `/Oy-`: turning off `/O1`, `/O2`, or `/O3` optimizations

The `-fno-omit-frame-pointer` option is set when you specify option `-O0` or the `-g` option. The `-fomit-frame-pointer` option is set when you specify option `-O1`, `-O2`, or `-O3`.

The `/Oy` option is set when you specify the `/O1`, `/O2`, or `/O3` option. Option `/Oy-` is set when you specify the `/Od` option.

Using the `-fno-omit-frame-pointer` or `/Oy-` option reduces the number of available general-purpose registers by 1, and can result in slightly less efficient code.

IDE Equivalent

Visual Studio: **Optimization > Omit Frame Pointers**

Eclipse: None

Xcode: **Optimization > Provide Frame Pointer**

Alternate Options

Linux and macOS*: `-fp` (this is a deprecated option)

Windows: None

See Also

momit-leaf-frame-pointer compiler option

guard

Enables the control flow protection mechanism.

Syntax

Linux OS:

`None`

macOS:

`None`

Windows OS:

`/guard:`*`keyword`*

Arguments

`keyword` Specifies the the control flow protection mechanism. Possible values are:

`cf[-]` Tells the compiler to analyze control flow of valid targets for indirect calls and to insert code to verify the targets at runtime.

To explicitly disable this option, specify `/guard:cf-`.

Default

`OFF` The control flow protection mechanism is disabled.

Description

This option enables the control flow protection mechanism. It tells the compiler to analyze control flow of valid targets for indirect calls and inserts a call to a checking routine before each indirect call to verify the target of the given indirect call.

The `/guard:cf` option must be passed to both the compiler and linker.

Code compiled using `/guard:cf` can be linked to libraries and object files that are not compiled using the option.

This option has been added for Microsoft compatibility. It uses the Microsoft implementation.

IDE Equivalent

None

Alternate Options

None

hotpatch

Tells the compiler to prepare a routine for hotpatching.

Syntax

Linux OS:

`-hotpatch[=n]`

macOS:

`None`

Windows OS:

`/hotpatch[:n]`

Arguments

n	An integer specifying the number of bytes the compiler should add before the function entry point.

Default

OFF	The compiler does not prepare routines for hotpatching.

Description

This option tells the compiler to prepare a routine for hotpatching. The compiler inserts nop padding around function entry points so that the resulting image is hot patchable.

Specifically, the compiler adds nop bytes after each function entry point and enough nop bytes before the function entry point to fit a direct jump instruction on the target architecture.

If *n* is specified, it overrides the default number of bytes that the compiler adds before the function entry point.

IDE Equivalent

None

Alternate Options

None

m

Tells the compiler which features it may target, including which instruction sets it may generate.

Syntax

Linux OS and macOS:

`-mcode`

Windows OS:

`None`

Arguments

code

Indicates to the compiler a feature set that it may target, including which instruction sets it may generate. Many of the following descriptions refer to Intel® Streaming SIMD Extensions (Intel® SSE) and Supplemental Streaming SIMD Extensions (SSSE). Possible values are:

`avx`	May generate Intel® Advanced Vector Extensions (Intel® AVX), SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
`sse4.2`	May generate Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
`sse4.1`	May generate Intel® SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
`ssse3`	May generate SSSE3 instructions and Intel® SSE3, SSE2, and SSE instructions.
`sse3`	May generate Intel® SSE3, SSE2, and SSE instructions.
`sse2`	May generate Intel® SSE2 and SSE instructions. This value is only available on Linux systems.
`sse`	This option has been deprecated; it is now the same as specifying `ia32`.
`ia32`	Generates x86/x87 generic code that is compatible with IA-32 architecture. Disables any default extended instruction settings, and any previously set extended instruction settings. It also disables all feature-specific optimizations and instructions. This value is only available on Linux* systems using IA-32 architecture.

This compiler option also supports many of the `-m` option settings available with gcc. For more information on gcc `-m` settings, see the gcc documentation.

Default

Linux* systems:
`-msse2`
macOS* systems:
`-mssse3`

For more information on the default values, see Arguments above.

Description

This option tells the compiler which features it may target, including which instruction sets it may generate.

Code generated with these options should execute on any compatible, non-Intel processor with support for the corresponding instruction set.

Options `-x` and `-m` are mutually exclusive. If both are specified, the compiler uses the last one specified and generates a warning.

Linux* systems: For compatibility with gcc, the compiler allows the following options but they have no effect. You will get a warning error, but the instructions associated with the name will not be generated. You should use the suggested replacement options.

gcc Compatibility Option (Linux*)	Suggested Replacement Option
`-mfma`	`-march=core-avx2`
`-mbmi, -mavx2, -mlzcnt`	`-march=core-avx2`
`-mmovbe`	`-march=atom -minstruction=movbe`
`-mcrc32, -maes, -mpclmul, -mpopcnt`	`-march=corei7`
`-mvzeroupper`	`-march=corei7-avx`
`-mfsgsbase, -mrdrnd, -mf16c`	`-march=core-avx-i`

IDE Equivalent

None

Alternate Options

Linux and macOS*: None

Windows: `/arch`

`ax, Qax` compiler option
`arch` compiler option
`march` compiler option
`m32, m64` compiler option

m32, m64, Qm32, Qm64

Tells the compiler to generate code for a specific architecture.

Syntax

Linux OS:

`-m32`

`-m64`

macOS:

`-m64`

Windows OS:

`/Qm32`

/Qm64

Arguments

None

Default

OFF The compiler's behavior depends on the host system.

Description

These options tell the compiler to generate code for a specific architecture.

Option	Description
-m32 or /Qm32	Tells the compiler to generate code for IA-32 architecture.
-m64 or /Qm64	Tells the compiler to generate code for Intel® 64 architecture.

The -m64 option is the same as macOS* option -arch x86_64. This option is not related to the Intel®Fortran Compiler option arch.

On Linux* systems, these options are provided for compatibility with gcc.

IDE Equivalent

None

Alternate Options

None

m80387

Specifies whether the compiler can use x87 instructions.

Syntax

Linux OS:

-m80387

-mno-80387

macOS:

-m80387

-mno-80387

Windows OS:

None

Arguments

None

Default

-m80387 The compiler may use x87 instructions.

Description

This option specifies whether the compiler can use x87 instructions.

If you specify option `-mno-80387`, it prevents the compiler from using x87 instructions. If the compiler is forced to generate x87 instructions, it issues an error message.

IDE Equivalent

None

Alternate Options

-m[no-]x87

march

Tells the compiler to generate code for processors that support certain features.

Syntax

Linux OS:

`-march=`*`processor`*

macOS:

`-march=`*`processor`*

Windows OS:

`None`

Arguments

processor

Indicates to the compiler the code it may generate. Possible values are:

`amberlake`
`broadwell`
`cannonlake`
`cascadelake`
`coffeelake`
`goldmont`
`goldmont-plus`
`haswell`
`icelake-client` (or `icelake`)
`icelake-server`
`ivybridge`
`kabylake`
`knl`
`knm`
`sandybridge`
`silvermont`
`skylake`
`skylake-avx512`
`tremont`
`whiskeylake`
	May generate instructions for processors that support the specified Intel® processor or microarchitecture code name.
	Keywords `knl` and `silvermont` are only available on Linux* systems.
	Keyword `icelake` is deprecated and may be removed in a future release.

`core-avx2`	Generates code for processors that support Intel® Advanced Vector Extensions 2 (Intel® AVX2), Intel® AVX, SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
`core-avx-i`	Generates code for processors that support the RDRND instruction, Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
`corei7-avx`	Generates code for processors that support Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
`corei7`	Generates code for processors that support Intel® SSE4 Efficient Accelerated String and Text Processing instructions. May also generate code for Intel® SSE4 Vectorizing Compiler and Media Accelerator, Intel® SSE3, SSE2, SSE, and SSSE3 instructions.
`atom`	Generates code for processors that support MOVBE instructions, depending on the setting of option `-minstruction` (Linux* and macOS*) or `/Qinstruction` (Windows*). May also generate code for SSSE3 instructions and Intel® SSE3, SSE2, and SSE instructions.
`core2`	Generates code for the Intel® Core™2 processor family.
`pentium4m`	Generates for Intel® Pentium® 4 processors with MMX technology.

`pentium-m`
`pentium4`
`pentium3`
`pentium`
	Generates code for Intel® Pentium® processors. Value `pentium3` is only available on Linux* systems.

Default

`pentium4`	If no architecture option is specified, value `pentium4` is used by the compiler to generate code.

Description

This option tells the compiler to generate code for processors that support certain features.

If you specify both the `-ax` and `-march` options, the compiler will not generate Intel-specific instructions.

Specifying `-march=pentium4` sets `-mtune=pentium4`.

For compatibility, a number of historical *processor* values are also supported, but the generated code will not differ from the default.

Optimization Notice
Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice. Notice revision #20110804

masm

Tells the compiler to generate the assembler output file using a selected dialect.

Syntax

Linux OS:

`-masm=`*`dialect`*

macOS:

`None`

Windows OS:

`None`

Arguments

dialect	Is the dialect to use for the assembler output file. Possible values are:
`att`	Tells the compiler to generate the assembler output file using AT&T* syntax.
`intel`	Tells the compiler to generate the assembler output file using Intel syntax.

Default

`-masm=att`	The compiler generates the assembler output file using AT&T* syntax.

Description

This option tells the compiler to generate the assembler output file using a selected dialect.

IDE Equivalent

None

Alternate Options

None

mauto-arch, Qauto-arch

Tells the compiler to generate multiple, feature-specific auto-dispatch code paths for x86 architecture processors if there is a performance benefit.

Syntax

Linux OS and macOS:

`-mauto-arch=`*`value`*

Windows OS:

`/Qauto-arch:`*`value`*

Arguments

`value`	Is any setting you can specify for option `[Q]ax`.

Default

OFF	No additional execution path is generated.

Description

This option tells the compiler to generate multiple, feature-specific auto-dispatch code paths for x86 architecture processors if there is a performance benefit. It also generates a baseline code path.

This option cannot be used together with any options that may require Intel-specific optimizations (such as `[Q]x` or `[Q]ax`).

IDE Equivalent

None

Alternate Options

None

ax, Qax compiler option

mbranches-within-32B-boundaries, Qbranches-within-32B-boundaries

Tells the compiler to align branches and fused branches on 32-byte boundaries for better performance.

Syntax

Linux OS:

`-mbranches-within-32B-boundaries`

`-mno-branches-within-32B-boundaries`

macOS:

`-mbranches-within-32B-boundaries`

`-mno-branches-within-32B-boundaries`

Windows OS:

`/Qbranches-within-32B-boundaries`

`/Qbranches-within-32B-boundaries-`

Arguments

None

Default

`-mno-branches-within-32B-boundaries` or `/Qbranches-within-32B-boundaries-`	Branches and fused branches are not aligned on 32-byte boundaries.

Description

This option tells the compiler to align branches and fused branches on 32-byte boundaries for better performance.

NOTE
When you use this option, it may affect binary utilities usage experience, such as debugability.

IDE Equivalent

None

Alternate Options

None

mconditional-branch, Qconditional-branch

Lets you identify and fix code that may be vulnerable to speculative execution side-channel attacks, which can leak your secure data as a result of bad speculation of a conditional branch direction.

Syntax

Linux OS:

`-mconditional-branch=`*keyword*

macOS:

`-mconditional-branch=`*keyword*

Windows OS:

`/Qconditional-branch:`*keyword*

Arguments

keyword Indicates to the compiler what action to take. Possible values are:

`keep`	Tells the compiler to not attempt any vulnerable code detection or fixing. This is equivalent to not specifying the `-mconditional-branch` option.
`pattern-report`	Tells the compiler to perform a search of vulnerable code patterns in the compilation and report all occurrences to stderr.
`pattern-fix`	Tells the compiler to perform a search of vulnerable code patterns in the compilation and generate code to ensure that the identified data accesses are not executed speculatively. It will also report any fixed patterns to stderr. This setting does not guarantee total mitigation, it only fixes cases where all components of the vulnerability can be seen or determined by the compiler. The pattern detection will be more complete if advanced optimization options are specified or are in effect, such as option `O3` and option `-ipo` (or `/Qipo`).
`all-fix`	Tells the compiler to fix all of the vulnerable code so that it is either not executed speculatively, or there is no observable side-channel created from their speculative execution. Since it is a complete mitigation against Spectre variant 1 attacks, this setting will have the most run-time performance cost. In contrast to the `pattern-fix` setting, the compiler will not attempt to identify the exact conditional branches that may have led to the mis-speculated execution.
`all-fix-lfence`	This is the same as specifying setting `all-fix`.
`all-fix-cmov`	Tells the compiler to treat any path where speculative execution of a memory load creates vulnerability (if mispredicted). The compiler automatically adds mitigation code along any vulnerable paths found, but it uses a different method then the one used for `all-fix` (or `all-fix-lfence`).

This method uses CMOVcc instruction execution, which constrains speculative execution. Thus, it is used for keeping track of the predicate value, which is updated on each conditional branch.

To prevent Spectre v.1 attack, each memory load that is potentially vulnerable is bitwise ORed with the predicate to mask out the loaded value if the code is on a mispredicted path.

This is analogous to the Clang compiler's option to do Speculative Load Hardening.

This setting is only supported on Intel® 64 architecture-based systems.

Default

`-mconditional-branch=keep` and `/Qconditional-branch:keep`	The compiler does not attempt any vulnerable code detection or fixing.

Description

This option lets you identify code that may be vulnerable to speculative execution side-channel attacks, which can leak your secure data as a result of bad speculation of a conditional branch direction. Depending on the setting you choose, vulnerabilities may be detected and code may be generated to attempt to mitigate the security risk.

IDE Equivalent

Visual Studio: **Code Generation > Spectre Variant 1 Mitigation**

Eclipse: None

Xcode: None

Alternate Options

None

minstruction, Qinstruction

Determines whether MOVBE instructions are generated for certain Intel processors.

Syntax

Linux OS and macOS:

`-minstruction=[no]movbe`

Windows OS:

`/Qinstruction:[no]movbe`

Arguments

None

Default

`-minstruction=nomovbe` or `/Qinstruction:nomovbe`	The compiler does not generate MOVBE instructions for Intel Atom® processors.

Description

This option determines whether MOVBE instructions are generated for Intel Atom® processors. To use this option, you must also specify `[Q]xATOM_SSSE3` or `[Q]xATOM_SSE4.2`.

If `-minstruction=movbe` or `/Qinstruction:movbe` is specified, the following occurs:

- MOVBE instructions are generated that are specific to the Intel Atom® processor.
- Generated executables can only be run on Intel Atom® processors or processors that support Supplemental Streaming SIMD Extensions 3 (Intel® SSSE3) or Intel® Streaming SIMD Extensions 4.2 (Intel® SSE4.2) and MOVBE.

If `-minstruction=nomovbe` or `/Qinstruction:nomovbe` is specified, the following occurs:

- The compiler optimizes code for the Intel Atom® processor, but it does not generate MOVBE instructions.
- Generated executables can be run on non-Intel Atom® processors that support Intel® SSE3 or Intel® SSE4.2.

IDE Equivalent

None

Alternate Options

None

`x, Qx` compiler option

momit-leaf-frame-pointer

Determines whether the frame pointer is omitted or kept in leaf functions.

Syntax

Linux OS:

```
-momit-leaf-frame-pointer
-mno-omit-leaf-frame-pointer
```

macOS:

```
-momit-leaf-frame-pointer
-mno-omit-leaf-frame-pointer
```

Windows OS:

```
None
```

Arguments

None

Default

Varies — If you specify option `-fomit-frame-pointer` (or it is set by default), the default is `-momit-leaf-frame-pointer`. If you specify option `-fno-omit-frame-pointer`, the default is `-mno-omit-leaf-frame-pointer`.

Description

This option determines whether the frame pointer is omitted or kept in leaf functions. It is related to option `-f[no-]omit-frame-pointer` and the setting for that option has an effect on this option.

Consider the following option combinations:

Option Combination	Result
`-fomit-frame-pointer -momit-leaf-frame-pointer` or `-fomit-frame-pointer -mno-omit-leaf-frame-pointer`	Both combinations are the same as specifying `-fomit-frame-pointer`. Frame pointers are omitted for all routines.
`-fno-omit-frame-pointer -momit-leaf-frame-pointer`	In this case, the frame pointer is omitted for leaf routines, but other routines will keep the frame pointer. This is the intended effect of option `-momit-leaf-frame-pointer`.
`-fno-omit-frame-pointer -mno-omit-leaf-frame-pointer`	In this case, `-mno-omit-leaf-frame-pointer` is ignored since `-fno-omit-frame-pointer` retains frame pointers in all routines . This combination is the same as specifying `-fno-omit-frame-pointer`.

This option is provided for compatibility with gcc.

IDE Equivalent

Visual Studio: None

Eclipse: None

Xcode: **Optimization > Provide Frame Pointer For Leaf Routines**

fomit-frame-pointer, Oy compiler option

mstringop-inline-threshold, Qstringop-inline-threshold

Tells the compiler to not inline calls to buffer manipulation functions such as memcpy and memset when the number of bytes the functions handle are known at compile time and greater than the specified value.

Syntax

Linux OS and macOS:

`-mstringop-inline-threshold=val`

Windows OS:

`/Qstringop-inline-threshold:val`

Arguments

val	Is a positive 32-bit integer. If the size is greater than *val*, the compiler will never inline it.

Default

OFF	The compiler uses its own heuristics to determine the default.

Description

This option tells the compiler to not inline calls to buffer manipulation functions such as memcpy and memset when the number of bytes the functions handle are known at compile time and greater than the specified *val*.

IDE Equivalent

None

Alternate Options

None

See Also

mstringop-strategy, Qstringop-strategy compiler option

mstringop-strategy, Qstringop-strategy

Lets you override the internal decision heuristic for the particular algorithm used when implementing buffer manipulation functions such as memcpy and memset.

Syntax

Linux OS and macOS:

`-mstringop-strategy=alg`

Windows OS:

`/Qstringop-strategy:alg`

Arguments

alg	Specifies the algorithm to use. Possible values are:	
	`const_size_loop`	Tells the compiler to expand the string operations into an inline loop when the size is known at compile time and it is not greater than threshold value. Otherwise, the compiler uses its own heuristics to decide how to implement the string operation.

`libcall`	Tells the compiler to use a library call when implementing string operations.
`rep`	Tells the compiler to use its own heuristics to decide what form of `rep movs | stos` to use when inlining string operations.

Default

varies	If optimization option `Os` is specified, the default is `rep`. Otherwise, the default is `const_size_loop`.

Description

This option lets you override the internal decision heuristic for the particular algorithm used when implementing buffer manipulation functions such as memcpy and memset.

This option may have no effect on compiler-generated string functions, for example, a call to memcpy generated by the compiler to implement an array copy or structure copy.

IDE Equivalent

None

Alternate Options

mstringop-inline-threshold, Qstringop-inline-threshold compiler option

Os compiler option

mtune, tune

Performs optimizations for specific processors but does not cause extended instruction sets to be used (unlike -march).

Syntax

Linux OS and macOS:

`-mtune=`*`processor`*

Windows OS:

`/tune:`*`processor`*

Arguments

processor

Is the processor for which the compiler should perform optimizations. Possible values are:

`generic`	Optimizes code for the compiler's default behavior.

`amberlake`
`broadwell`
`cannonlake`
`cascadelake`
`coffeelake`
	Optimizes code for processors that support the specified Intel® processor or microarchitecture code name.
	Keywords `knl` and `silvermont` are only available on Windows* and Linux* systems.

`goldmont`
`goldmont-plus`
`haswell`
`icelake-client` (or `icelake`)
`icelake-server`
`ivybridge`
`kabylake`
`knl`
`knm`
`sandybridge`
`silvermont`
`skylake`
`skylake-avx512`
`tremont`
`whiskeylake`
	Keyword `icelake` is deprecated and may be removed in a future release.

`core-avx2`	Optimizes code for processors that support Intel® Advanced Vector Extensions 2 (Intel® AVX2), Intel® AVX, SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
`core-avx-i`	Optimizes code for processors that support the RDRND instruction, Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
`corei7-avx`	Optimizes code for processors that support Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions.
`corei7`	Optimizes code for processors that support Intel® SSE4 Efficient Accelerated String and Text Processing instructions. May also generate code for Intel® SSE4 Vectorizing Compiler and Media Accelerator, Intel® SSE3, SSE2, SSE, and SSSE3 instructions.
`atom`	Optimizes code for processors that support MOVBE instructions, depending on the setting of option `-minstruction` (Linux* and macOS*) or `/Qinstruction` (Windows*). May also generate code for SSSE3 instructions and Intel® SSE3, SSE2, and SSE instructions.
`core2`	Optimizes for the Intel® Core™2 processor family, including support for MMX™, Intel® SSE, SSE2, SSE3 and SSSE3 instruction sets.
`pentium-mmx`	Optimizes for Intel® Pentium® with MMX technology.

`pentiumpro`	Optimizes for Intel® Pentium® Pro, Intel Pentium II, and Intel Pentium III processors.
`pentium4m`	Optimizes for Intel® Pentium® 4 processors with MMX technology.

`pentium-m`
`pentium4`
`pentium3`
`pentium`
	Optimizes code for Intel® Pentium® processors. Value `pentium3` is only available on Linux* systems.

Default

generic	Code is generated for the compiler's default behavior.

Description

This option performs optimizations for specific processors but does not cause extended instruction sets to be used (unlike `-march`).

The resulting executable is backwards compatible and generated code is optimized for specific processors. For example, code generated with `-mtune=core2` or `/tune:core2` will run correctly on 4th Generation Intel® Core™ processors, but it might not run as fast as if it had been generated using `-mtune=haswell` or `/tune:haswell`. Code generated with `-mtune=haswell` (`/tune:haswell`) or `-mtune=core-avx2` (`/tune:core-avx2`) will also run correctly on Intel® Core™2 processors, but it might not run as fast as if it had been generated using `-mtune=core2` or `/tune:core2`. This is in contrast to code generated with `-march=core-avx2` or `/arch:core-avx2`, which will not run correctly on older processors such as Intel® Core™2 processors.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. `march` compiler option

qcf-protection, Qcf-protection

Enables Control-flow Enforcement Technology (CET) protection, which defends your program from certain attacks that exploit vulnerabilities. This option offers preliminary support for CET.

Syntax

Linux OS:

`-qcf-protection[=keyword]`

macOS:

`None`

Windows OS:

`/Qcf-protection[:keyword]`

Arguments

keyword Specifies the level of protection the compiler should perform. Possible values are:

`shadow_stack`	Enables shadow stack protection.
`branch_tracking`	Enables endbranch (EB) generation.
`full`	Enables both shadow stack protection and endbranch (EB) generation. This is the same as specifying the `[q or Q]cf-protection` option with no *keyword*.
`none`	Disables Control-flow Enforcement Technology (CET) protection.

Default

`-qcf-protection=none` No Control-flow Enforcement protection is performed.

or
`/Qcf-protection:none`

Description

This option enables Control-flow Enforcement Technology (CET) protection, which defends your program from certain attacks that exploit vulnerabilities.

CET protections are enforced on processors that support CET. They are ignored on processors that do not support CET, so they are safe to use in programs that might run on a variety of processors.

Specifying `shadow_stack` helps to protect your program from return-oriented programming (ROP). Return-oriented programming (ROP) is a technique to exploit computer security defenses such as non-executable memory and code signing by gaining control of the call stack to modify program control flow and then execute certain machine instruction sequences.

Specifying `branch_tracking` helps to protect your program from call/jump-oriented programming (COP/JOP). Jump-oriented programming (JOP) is a variant of ROP that uses indirect jumps and calls to emulate return instructions. Call-oriented programming (COP) is a variant of ROP that employs indirect calls.

To get both protections, specify `[q or Q]cf-protection` with no *keyword*, or specify `-qcf-protection=full` (Linux*) or `/Qcf-protection:full` (Windows*).

> **NOTE**
> On Linux and macOS* systems, you can also specify gcc option `-fcf-protection` to enable CET features. For more information about that option, see the gcc documentation.

IDE Equivalent

None

Alternate Options

Linux and macOS*: `-fcf-protection` (supported gcc option)

Windows: None

guard compiler option

Qpatchable-addresses

Tells the compiler to generate code such that references to statically assigned addresses can be patched.

Architecture Restrictions

Only available on Intel® 64 architecture

Syntax

Linux OS:

`None`

macOS:

`None`

Windows OS:

`/Qpatchable-addresses`

Arguments

None

Default

OFF The compiler does not generate patchable addresses.

Description

This option tells the compiler to generate code such that references to statically assigned addresses can be patched with arbitrary 64-bit addresses.

Normally, the Windows* system compiler that runs on Intel® 64 architecture uses 32-bit relative addressing to reference statically allocated code and data. That assumes the code or data is within 2GB of the access point, an assumption that is enforced by the Windows object format.

However, in some patching systems, it is useful to have the ability to replace a global address with some other arbitrary 64-bit address, one that might not be within 2GB of the access point.

This option causes the compiler to avoid 32-bit relative addressing in favor of 64-bit direct addressing so that the addresses can be patched in place without additional code modifications. This option causes code size to increase, and since 32-bit relative addressing is usually more efficient than 64-bit direct addressing, you may see a performance impact.

IDE Equivalent

None

Alternate Options

None

x, Qx

Tells the compiler which processor features it may target, including which instruction sets and optimizations it may generate.

Syntax

Linux OS and macOS:

`-x`*code*

Windows OS:

`/Qx`*code*

Arguments

code

Indicates to the compiler a feature set that it may target, including which instruction sets and optimizations it may generate. Many of the following descriptions refer to Intel® Streaming SIMD Extensions (Intel® SSE) and Supplemental Streaming SIMD Extensions (Intel® SSSE). Possible values are:

`AMBERLAKE`
`BROADWELL`
`CANNONLAKE`
`CASCADELAKE`
`COFFEELAKE`
`GOLDMONT`
`GOLDMONT-PLUS`
`HASWELL`
`ICELAKE-CLIENT` (or `ICELAKE`)
`ICELAKE-SERVER`
`IVYBRIDGE`
`KABYLAKE`
`KNL`
`KNM`
`SANDYBRIDGE`
	May generate instructions for processors that support the specified Intel® processor or microarchitecture code name. Optimizes for the specified Intel® processor or microarchitecture code name.
	
	Keywords `KNL` and `SILVERMONT` are only available on Windows* and Linux* systems.
	
	Keyword `ICELAKE` is deprecated and may be removed in a future release.

SILVERMONT SKYLAKE SKYLAKE-AVX512 TREMONT WHISKEYLAKE	
COMMON-AVX512	May generate Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Foundation instructions, Intel® AVX-512 Conflict Detection instructions, as well as the instructions enabled with CORE-AVX2. Optimizes for Intel® processors that support Intel® AVX-512 instructions.
CORE-AVX512	May generate Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Foundation instructions, Intel® AVX-512 Conflict Detection instructions, Intel® AVX-512 Doubleword and Quadword instructions, Intel® AVX-512 Byte and Word instructions and Intel® AVX-512 Vector Length extensions, as well as the instructions enabled with CORE-AVX2. Optimizes for Intel® processors that support Intel® AVX-512 instructions.
CORE-AVX2	May generate Intel® Advanced Vector Extensions 2 (Intel® AVX2), Intel® AVX, SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors. Optimizes for Intel® processors that support Intel® AVX2 instructions.
CORE-AVX-I	May generate the RDRND instruction, Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors. Optimizes for Intel® processors that support the RDRND instruction.
AVX	May generate Intel® Advanced Vector Extensions (Intel® AVX), Intel® SSE4.2, SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors. Optimizes for Intel processors that support Intel® AVX instructions.
SSE4.2	May generate Intel® SSE4 Efficient Accelerated String and Text Processing instructions, Intel® SSE4 Vectorizing Compiler and Media Accelerator, and Intel® SSE3, SSE2, SSE, and SSSE3 instructions for Intel® processors. Optimizes for Intel processors that support Intel® SSE4.2 instructions.

`SSE4.1`	May generate Intel® SSE4 Vectorizing Compiler and Media Accelerator instructions for Intel® processors. May generate Intel® SSE4.1, SSE3, SSE2, SSE, and SSSE3 instructions for Intel processors that support Intel® SSE4.1 instructions.
`ATOM_SSE4.2`	May generate MOVBE instructions for Intel® processors, depending on the setting of option `-minstruction` (Linux* and macOS*) or `/Qinstruction` (Windows*). May also generate Intel® SSE4.2, SSE3, SSE2, and SSE instructions for Intel processors. Optimizes for Intel Atom® processors that support Intel® SSE4.2 and MOVBE instructions. This keyword is only available on Windows* and Linux* systems.
`ATOM_SSSE3`	May generate MOVBE instructions for Intel® processors, depending on the setting of option `-minstruction` (Linux* and macOS*) or `/Qinstruction` (Windows*). May also generate SSSE3, Intel® SSE3, SSE2, and SSE instructions for Intel processors. Optimizes for Intel Atom® processors that support Intel® SSE3 and MOVBE instructions. This keyword is only available on Windows* and Linux* systems.
`SSSE3`	May generate SSSE3 and Intel® SSE3, SSE2, and SSE instructions for Intel® processors. Optimizes for Intel processors that support SSSE3 instructions. For macOS* systems, this value is only supported on Intel® 64 architecture. This replaces value T, which is deprecated.
`SSE3`	May generate Intel® SSE3, SSE2, and SSE instructions for Intel® processors. Optimizes for Intel processors that support Intel® SSE3 instructions. This value is not available on macOS* systems.
`SSE2`	May generate Intel® SSE2 and SSE instructions for Intel® processors. Optimizes for Intel processors that support Intel® SSE2 instructions. This value is not available on macOS* systems.

You can also specify `Host`. For more information, see option `[Q]xHost`.

Default

Windows* systems: None Linux* systems: None macOS* systems: `SSSE3`	On Windows systems, if neither `/Qx` nor `/arch` is specified, the default is `/arch:SSE2`. On Linux systems, if neither `-x` nor `-m` is specified, the default is `-msse2`.

Description

This option tells the compiler which processor features it may target, including which instruction sets and optimizations it may generate. It also enables optimizations in addition to Intel feature-specific optimizations.

The specialized code generated by this option may only run on a subset of Intel® processors.

The resulting executables created from these option *code* values can only be run on Intel® processors that support the indicated instruction set.

The binaries produced by these *code* values will run on Intel® processors that support the specified features.

Do not use *code* values to create binaries that will execute on a processor that is not compatible with the targeted processor. The resulting program may fail with an illegal instruction exception or display other unexpected behavior.

Compiling the main program with any of the *code* values produces binaries that display a fatal run-time error if they are executed on unsupported processors, including all non-Intel processors.

Compiler options `m` and `arch` produce binaries that should run on processors not made by Intel that implement the same capabilities as the corresponding Intel® processors.

The `-x` and `/Qx` options enable additional optimizations not enabled with options `-m` or `/arch` (nor with options `-ax` and `/Qax`).

On Windows systems, options `/Qx` and /arch are mutually exclusive. If both are specified, the compiler uses the last one specified and generates a warning. Similarly, on Linux and macOS* systems, options `-x` and `-m` are mutually exclusive. If both are specified, the compiler uses the last one specified and generates a warning.

NOTE
All settings except SSE2 do a CPU check. However, if you specify option -O0 (Linux* or macOS*) or option /Od (Windows*), no CPU check is performed.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

xHost, QxHost

Tells the compiler to generate instructions for the highest instruction set available on the compilation host processor.

Syntax

Linux OS and macOS:

`-xHost`

Windows OS:

`/QxHost`

Arguments

None

Default

Windows* systems: None Linux* systems: None macOS* systems: `-xSSSE3`	On Windows systems, if neither `/Qx` nor `/arch` is specified, the default is `/arch:SSE2`. On Linux systems, if neither `-x` nor `-m` is specified, the default is `-msse2`.

Description

This option tells the compiler to generate instructions for the highest instruction set available on the compilation host processor.

The instructions generated by this compiler option differ depending on the compilation host processor.

The following table describes the effects of specifying the `[Q]xHost` option and it tells whether the resulting executable will run on processors different from the host processor.

Descriptions in the table refer to Intel® Advanced Vector Extensions 2 (Intel® AVX2), Intel® Advanced Vector Extensions (Intel® AVX), Intel® Streaming SIMD Extensions (Intel® SSE), and Supplemental Streaming SIMD Extensions (SSSE).

Instruction Set of Host Processor	Effects When the -xHost or /QxHost Compiler Option is Specified
Intel® AVX2	When compiling on Intel® processors: Corresponds to option `[Q]xCORE-AVX2`. The generated executable will not run on non-Intel processors and it will not run on Intel® processors that do not support Intel® AVX2 instructions. When compiling on non-Intel processors: Corresponds to option `-march=core-avx2` (Linux* and macOS*) or `/arch:CORE-AVX2` (Windows*). The generated executable will run on Intel® processors and non-Intel processors that support at least Intel® AVX2 instructions.. You may see a run-time error if the run-time processor does not support Intel® AVX2 instructions.
Intel® AVX	When compiling on Intel® processors: Corresponds to option `[Q]xAVX`. The generated executable will not run on non-Intel processors and it will not run on Intel® processors that do not support Intel® AVX instructions. When compiling on non-Intel processors: Corresponds to option `-mavx` (Linux and macOS*) or `/arch:AVX` (Windows). The generated executable will run on Intel® processors and non-Intel processors that support at least Intel® AVX instructions. You may see a run-time error if the run-time processor does not support Intel® AVX instructions.
Intel® SSE4.2	When compiling on Intel® processors: Corresponds to option `[Q]xSSE4.2`. The generated executable will not run on non-Intel processors and it will not run on Intel® processors that do not support Intel® SSE4.2 instructions. When compiling on non-Intel processors: Corresponds to option `-msse4.2` (Linux and macOS*) or `/arch:SSE4.2` (Windows). The generated executable will run on Intel® processors and non-Intel processors that support at least Intel® SSE4.2 instructions. You may see a run-time error if the run-time processor does not support Intel® SSE4.2 instructions.
Intel® SSE4.1	When compiling on Intel® processors: Corresponds to option `[Q]xSSE4.1`. The generated executable will not run on non-Intel processors and it will not run on Intel® processors that do not support Intel® SSE4.1 instructions. When compiling on non-Intel processors: Corresponds to option `-msse4.1` (Linux and macOS*) or `/arch:SSE4.1` (Windows). The generated executable will run on Intel® processors and non-Intel processors that support at least Intel® SSE4.1 instructions. You may see a run-time error if the run-time processor does not support Intel® SSE4.1 instructions.
SSSE3	When compiling on Intel® processors:

Instruction Set of Host Processor	Effects When the -xHost or /QxHost Compiler Option is Specified
	Corresponds to option `[Q]xSSSE3`. The generated executable will not run on non-Intel processors and it will not run on Intel® processors that do not support SSSE3 instructions. When compiling on non-Intel processors: Corresponds to option `-mssse3` (Linux and macOS*) or `/arch:SSSE3` (Windows). The generated executable will run on Intel® processors and non-Intel processors that support at least SSSE3 instructions. You may see a run-time error if the run-time processor does not support SSSE3 instructions.
Intel® SSE3	When compiling on Intel® processors: Corresponds to option `[Q]xSSE3`. The generated executable will not run on non-Intel processors and it will not run on Intel® processors that do not support Intel® SSE3 instructions. When compiling on non-Intel processors: Corresponds to option `-msse3` (Linux and macOS*) or `/arch:SSE3` (Windows). The generated executable will run on Intel® processors and non-Intel processors that support at least Intel® SSE3 instructions. You may see a warning run-time error if the run-time processor does not support Intel® SSE3 instructions.
Intel® SSE2	When compiling on Intel® processors or non-Intel processors: Corresponds to option `-msse2` (Linux and macOS*) or `/arch:SSE2` (Windows). The generated executable will run on Intel® processors and non-Intel processors that support at least Intel® SSE2 instructions. You may see a run-time error if the run-time processor does not support Intel® SSE2 instructions.

For more information on other settings for option `[Q]x`, see that option description.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Interprocedural Optimization (IPO) Options

ffat-lto-objects

Determines whether a fat link-time optimization (LTO) object, containing both intermediate language and object code, is generated during an interprocedural optimization compilation (-c –ipo).

Syntax

Linux OS:

`-ffat-lto-objects`

`-fno-fat-lto-objects`

macOS:

`None`

Windows OS:

`None`

Arguments

None

Default

`-ffat-lto-objects` When `-c -ipo` is specified, the compiler generates a fat link-time optimization (LTO) object that has both a true object and a discardable intermediate language section.

Description

This option determines whether a fat link time optimization (LTO) object, containing both intermediate language and object code, is generated during an interprocedural optimization compilation (`-c -ipo`).

During an interprocedural optimization compilation (`-c -ipo`), the following occurs:

- If you specify `-ffat-lto-objects`, the compiler generates a fat link-time optimization (LTO) object that has both a true object and a discardable intermediate language section. This enables both link-time optimization (LTO) linking and normal linking.
- If you specify `-fno-fat-lto-objects`, the compiler generates a fat link-time optimization (LTO) object that only has a discardable intermediate language section; no true object is generated. This option may improve compilation time.

Note that these files will be inserted into archives in the form in which they were created.

This option is provided for compatibility with gcc. For more information about this option, see the gcc documentation.

NOTE
Intel's intermediate language representation is not compatible with gcc's intermediate language representation.

IDE Equivalent

None

Alternate Options

None

See Also

`ipo, Qipo` compiler option

ip, Qip

Determines whether additional interprocedural optimizations for single-file compilation are enabled.

Syntax

Linux OS and macOS:

`-ip`

`-no-ip`

Windows OS:

`/Qip`

`/Qip-`

Arguments

None

Default

OFF Some limited interprocedural optimizations occur, including inline function expansion for calls to functions defined within the current source file. These optimizations are a subset of full intra-file interprocedural optimizations. Note that this setting is not the same as `-no-ip` (Linux* and macOS*) or `/Qip-` (Windows*).

Description

This option determines whether additional interprocedural optimizations for single-file compilation are enabled.

The `[Q]ip` option enables additional interprocedural optimizations for single-file compilation.

Options `-no-ip` (Linux and macOS*) and `/Qip-` (Windows) may not disable inlining. To ensure that inlining of user-defined functions is disabled, specify `-inline-level=0`or `-fno-inline` (Linux and macOS*), or specify `/Ob0` (Windows).

IDE Equivalent

Visual Studio: **Optimization > Interprocedural Optimization**

Eclipse: None

Xcode: None

Alternate Options

None

See Also

`finline-functions` compiler option

ip-no-inlining, Qip-no-inlining

Disables full and partial inlining enabled by interprocedural optimization options.

Syntax

Linux OS and macOS:

`-ip-no-inlining`

Windows OS:

`/Qip-no-inlining`

Arguments

None

Default

OFF Inlining enabled by interprocedural optimization options is performed.

Description

This option disables full and partial inlining enabled by the following interprocedural optimization options:

- On Linux* and macOS* systems: `-ip` or `-ipo`
- On Windows* systems: `/Qip`, `/Qipo`, or `/Ob2`

It has no effect on other interprocedural optimizations.

On Windows systems, this option also has no effect on user-directed inlining specified by option `/Ob1`.

IDE Equivalent

None

Alternate Options

None

ip-no-pinlining, Qip-no-pinlining

Disables partial inlining enabled by interprocedural optimization options.

Syntax

Linux OS and macOS:

`-ip-no-pinlining`

Windows OS:

`/Qip-no-pinlining`

Arguments

None

Default

OFF Inlining enabled by interprocedural optimization options is performed.

Description

This option disables partial inlining enabled by the following interprocedural optimization options:

- On Linux* and macOS* systems: `-ip` or `-ipo`
- On Windows* systems: `/Qip` or `/Qipo`

It has no effect on other interprocedural optimizations.

IDE Equivalent

None

Alternate Options

None

ipo, Qipo

Enables interprocedural optimization between files.

Syntax

Linux OS:

`-ipo[n]`

`-no-ipo`

macOS:

`-ipo[n]`

`-no-ipo`

Windows OS:

`/Qipo[n]`

`/Qipo-`

Arguments

n	Is an optional integer that specifies the number of object files the compiler should create. The integer must be greater than or equal to 0.

Default

`-no-ipo` or `/Qipo-` Multifile interprocedural optimization is not enabled.

Description

This option enables interprocedural optimization between files. This is also called multifile interprocedural optimization (multifile IPO) or Whole Program Optimization (WPO).

When you specify this option, the compiler performs inline function expansion for calls to functions defined in separate files.

You cannot specify the names for the files that are created.

If *n* is 0, the compiler decides whether to create one or more object files based on an estimate of the size of the application. It generates one object file for small applications, and two or more object files for large applications.

If *n* is greater than 0, the compiler generates *n* object files, unless *n* exceeds the number of source files (*m*), in which case the compiler generates only *m* object files.

If you do not specify *n*, the default is 0.

NOTE
When you specify option `[Q]ipo` with option `[q or Q]opt-report`, IPO information is generated in the compiler optimization report at link time. After linking, you will see a report named ipo_out.optrpt in the folder where you linked all of the object files.

IDE Equivalent

Visual Studio: **Optimization > Interprocedural Optimization**

General > Whole Program Optimization

Eclipse: None

Xcode: None

Alternate Options

None

ipo-c, Qipo-c

Tells the compiler to optimize across multiple files and generate a single object file.

Syntax

Linux OS and macOS:

`-ipo-c`

Windows OS:

`/Qipo-c`

Arguments

None

Default

OFF The compiler does not generate a multifile object file.

Description

This option tells the compiler to optimize across multiple files and generate a single object file (named ipo_out.o on Linux* and macOS* systems; ipo_out.obj on Windows* systems).

It performs the same optimizations as the `[Q]ipo` option, but compilation stops before the final link stage, leaving an optimized object file that can be used in further link steps.

IDE Equivalent

None

Alternate Options

None

See Also

`ipo, Qipo` compiler option

ipo-jobs, Qipo-jobs

Specifies the number of commands (jobs) to be executed simultaneously during the link phase of Interprocedural Optimization (IPO).

Syntax

Linux OS and macOS:

`-ipo-jobs`*n*

Windows OS:

`/Qipo-jobs:`*n*

Arguments

n	Is the number of commands (jobs) to run simultaneously. The number must be greater than or equal to 1.

Default

`-ipo-jobs1` or `/Qipo-jobs:1`	One command (job) is executed in an interprocedural optimization parallel build.

Description

This option specifies the number of commands (jobs) to be executed simultaneously during the link phase of Interprocedural Optimization (IPO). It should only be used if the link-time compilation is generating more than one object. In this case, each object is generated by a separate compilation, which can be done in parallel.

This option can be affected by the following compiler options:

- `[Q]ipo` when applications are large enough that the compiler decides to generate multiple object files.
- `[Q]ipo`*n* when *n* is greater than 1.
- `[Q]ipo-separate`

Caution
Be careful when using this option. On a multi-processor system with lots of memory, it can speed application build time. However, if *n* is greater than the number of processors, or if there is not enough memory to avoid thrashing, this option can increase application build time.

IDE Equivalent

None

Alternate Options

None

See Also

`ipo, Qipo` compiler option

`ipo-separate, Qipo-separate` compiler option

ipo-S, Qipo-S

Tells the compiler to optimize across multiple files and generate a single assembly file.

Syntax

Linux OS and macOS:

`-ipo-S`

Windows OS:

`/Qipo-S`

Arguments

None

Default

OFF The compiler does not generate a multifile assembly file.

Description

This option tells the compiler to optimize across multiple files and generate a single assembly file (named ipo_out.s on Linux* and macOS* systems; ipo_out.asm on Windows* systems).

It performs the same optimizations as the `[Q]ipo` option, but compilation stops before the final link stage, leaving an optimized assembly file that can be used in further link steps.

IDE Equivalent

None

Alternate Options

None

See Also

`ipo, Qipo` compiler option

ipo-separate, Qipo-separate

Tells the compiler to generate one object file for every source file.

Syntax

Linux OS:

`-ipo-separate`

macOS:

`None`

Windows OS:

`/Qipo-separate`

Arguments

None

Default

OFF The compiler decides whether to create one or more object files.

Description

This option tells the compiler to generate one object file for every source file. It overrides any `[Q]ipo` option specification.

IDE Equivalent

None

Alternate Options

None

See Also

`ipo, Qipo` compiler option

Advanced Optimization Options

ansi-alias, Qansi-alias

Tells the compiler to assume certain rules of the Fortran standard regarding aliasing and array bounds.

Syntax

Linux OS and macOS:

`-ansi-alias`

`-no-ansi-alias`

Windows OS:

`/Qansi-alias`

`/Qansi-alias-`

Arguments

None

Default

`-ansi-alias` Programs adhere to the Fortran standard's rules regarding aliasing and array bounds.
or
`/Qansi-alias`

Description

This option tells the compiler to assume certain rules of the Fortran standard regarding aliasing and array bounds.

It tells the compiler to assume that the program adheres to the following rules of the Fortran standard:

- Arrays cannot be accessed outside of declared bounds.
- A dummy argument may have its definition status changed only through that dummy argument, unless it has the TARGET attribute.

This option is similar to option `assume nodummy_aliases` with the additional restriction on array bounds.

If `-no-ansi-alias` (Linux* and macOS*) or `/Qansi-alias-` (Windows*) is specified, the compiler assumes that the program might not follow the Fortran standard's rules regarding dummy argument aliasing and array bounds; this can possibly affect performance.

IDE Equivalent

None

Alternate Options

None

See Also

`assume` compiler option, setting [no]dummy_aliases

coarray, Qcoarray

Enables the coarray feature.

Syntax

Linux OS:

`-coarray[=keyword]`

macOS:

`None`

Windows OS:

`/Qcoarray[:keyword]`

Arguments

keyword Specifies the memory system where the coarrays will be implemented. Possible values are:

`shared`	Indicates a shared memory system. This is the default.
`distributed`	Indicates a distributed memory system.
`single`	Indicates a configuration where the image does not contain self-replication code. This results in an executable with a single running image. This configuration can be useful for debugging purposes, even though there are no inter-image interactions.

Default

OFF Coarrays are not enabled without specifying this option.

Description

This option enables the coarray feature of the Fortran 2008 Standard. It enables any coarray syntax in your program. If this option is not specified, coarray syntax is rejected.

It also tells the driver to link against appropriate libraries, and to create the appropriate executables.

Only one *keyword* can be in effect. If you specify more than one *keyword*, the last one specified takes precedence. However, if *keyword* single is specified anywhere on the command line, it takes precedence.

You can specify option `[Q]coarray-num-images` to specify the default number of images that can be used to run a coarray executable. If you do not specify that option, you get the number of execution units on the current system.

You can specify the `[Q]coarray-config-file` option to specify the name of a Message Passing Interface (MPI) configuration file.

Options `[Q]coarray-num-images` and `[Q]coarray-config-file` are valid for all *keyword* values.

NOTE
32-bit coarrays are deprecated and will be removed in a future release.

IDE Equivalent

Visual Studio: **Language > Enable Coarrays**

Eclipse: None

Xcode: None

Alternate Options

None

Example

The following command runs a coarray program on shared memory using *n* images:

```
/Qcoarray /Qcoarray-num-images:n          ! Windows systems
```

```
-coarray -coarray-num-images=n            ! Linux systems
```

The following command runs a coarray program on distributed memory using *n* images:

```
/Qcoarray:distributed /Qcoarray-num-images:n          ! Windows systems
```

```
-coarray=distributed -coarray-num-images=n            ! Linux systems
```

The following command runs a coarray program on shared memory using the MPI configuration file specified by *filename*:

```
/Qcoarray:shared /Qcoarray-config-file:filename        ! Windows systems
```

```
-coarray=shared -coarray-config-file=filename          ! Linux systems
```

The following commands illustrate precedence:

Linux* systems:

```
-coarray=single -coarray=shared               ! single takes precedence (single always takes
precedence)
```

Windows* systems:

```
/Qcoarray:distributed /Qcoarray:shared        ! shared takes precedence (last one specified)
```

```
/Qcoarray:single /Qcoarray:shared             ! single takes precedence (single always takes
precedence)
```

See Also

`coarray-num-images, Qcoarray-num-images` compiler option

`coarray-config-file, Qcoarray-config-file` compiler option

Coarrays
Using Coarrays

coarray-config-file, Qcoarray-config-file

Specifies the name of a Message Passing Interface (MPI) configuration file.

Syntax

Linux OS:

`-coarray-config-file=`*`filename`*

macOS:

`None`

Windows OS:

`/Qcoarray-config-file:`*`filename`*

Arguments

filename	Is the name of the MPI configuration file. You can specify a path.

Default

OFF	When coarrays are enabled, the compiler uses default settings for MPI.

Description

This option specifies the name of a Message Passing Interface (MPI) configuration file. This file is used by the compiler when coarrays are processed; it configures the MPI for multi-node operations.

This option has no affect unless you also specify the `[Q]coarray` option, which is required to create the coarray executable.

Note that when a setting is specified in environment variable FOR_COARRAY_CONFIG_FILE, it overrides the compiler option setting.

IDE Equivalent

Visual Studio: **Language > MPI Configuration File**

Eclipse: None

Xcode: None

Alternate Options

None

See Also

`coarray, Qcoarray` compiler option

coarray-num-images, Qcoarray-num-images

Specifies the default number of images that can be used to run a coarray executable.

Syntax

Linux OS:

`-coarray-num-images=n`

macOS:

`None`

Windows OS:

`/Qcoarray-num-images:n`

Arguments

n	Is the default number of images. The limit is determined from the system configuration.

Default

OFF	The number of images is determined at run-time.

Description

This option specifies the default number of images that can be used to run a coarray executable.

This option has no affect unless you also specify the `[Q]coarray` option. This option is required to create the coarray executable.

You can specify option `[Q]coarray-num-images` to specify the default number of images that can be used to run a coarray executable. If you do not specify that option, you get the number of execution units on the current system.

Note that when a setting is specified in environment variable FOR_COARRAY_NUM_IMAGES, it overrides the compiler option setting.

IDE Equivalent

Visual Studio: **Language > Coarray Images**

Eclipse: None

Xcode: None

Alternate Options

None

See Also

`coarray, Qcoarray` compiler option

complex-limited-range, Qcomplex-limited-range

Determines whether the use of basic algebraic expansions of some arithmetic operations involving data of type COMPLEX is enabled.

Syntax

Linux OS and macOS:

`-complex-limited-range`

`-no-complex-limited-range`

Windows OS:

`/Qcomplex-limited-range`

`/Qcomplex-limited-range-`

Arguments

None

Default

`-no-complex-limited-range` or `/Qcomplex-limited-range-`	Basic algebraic expansions of some arithmetic operations involving data of type COMPLEX are disabled.

Description

This option determines whether the use of basic algebraic expansions of some arithmetic operations involving data of type COMPLEX is enabled.

When the option is enabled, this can cause performance improvements in programs that use a lot of COMPLEX arithmetic. However, values at the extremes of the exponent range may not compute correctly.

IDE Equivalent

Visual Studio: **Floating point > Limit COMPLEX Range**

Eclipse: None

Xcode: **Floating point > Limit COMPLEX Range**

Alternate Options

None

guide, Qguide

Lets you set a level of guidance for auto-vectorization, auto parallelism, and data transformation.

Syntax

Linux OS and macOS:

`-guide[=n]`

Windows OS:

`/Qguide[:n]`

Arguments

n	Is an optional value specifying the level of guidance to be provided. The values available are 1 through 4. Value 1 indicates a standard level of guidance. Value 4 indicates the most advanced level of guidance. If *n* is omitted, the default is 4.

Default

OFF	You do not receive guidance about how to improve optimizations for parallelism, vectorization, and data transformation.

Description

This option lets you set a level of guidance (advice) for auto-vectorization, auto parallelism, and data transformation. It causes the compiler to generate messages suggesting ways to improve these optimizations.

When this option is specified, the compiler does not produce any objects or executables.

You must also specify the `[Q]parallel` option to receive auto parallelism guidance.

You can set levels of guidance for the individual guide optimizations by specifying one of the following options:

`[Q]guide-data-trans`	Provides guidance for data transformation.
`[Q]guide-par`	Provides guidance for auto parallelism.
`[Q]guide-vec`	Provides guidance for auto-vectorization.

If you specify the `[Q]guide` option and also specify one of the options setting a level of guidance for an individual guide optimization, the value set for the individual guide optimization will override the setting specified in `[Q]guide`.

If you do not specify `[Q]guide`, but specify one of the options setting a level of guidance for an individual guide optimization, option `[Q]guide` is enabled with the greatest value passed among any of the three individual guide optimizations specified.

In debug mode, this option has no effect unless option `O2` (or higher) is explicitly specified in the same command line.

NOTE
The compiler speculatively performs optimizations as part of guide analysis. As a result, when you use guided auto-parallelism options with options that produce vectorization or auto-parallelizer reports (such as option `[q or Q]opt-report`), the compiler generates "LOOP WAS VECTORIZED" or similar messages as if the compilation was performed with the recommended changes.

When compilation is performed with the `[Q]guide` option, you should use extra caution when interpreting vectorizer diagnostics and auto-parallelizer diagnostics.

NOTE
You can specify `[Q]diag-disable` to prevent the compiler from issuing one or more diagnostic messages.

IDE Equivalent

Visual Studio: **Diagnostics > Guided Auto Parallelism > Guided Auto Parallelism Analysis**

Eclipse: None

Xcode: **Diagnostics > Enable Guided Auto Parallelism Analysis**

Alternate Options

None

guide-opts, Qguide-opts compiler option
diag, Qdiag compiler option
qopt-report, Qopt-report compiler option

guide-data-trans, Qguide-data-trans

Lets you set a level of guidance for data transformation.

Syntax

Linux OS and macOS:

`-guide-data-trans[=n]`

Windows OS:

`/Qguide-data-trans[:n]`

Arguments

n	Is an optional value specifying the level of guidance to be provided. The values available are 1 through 4. Value 1 indicates a standard level of guidance. Value 4 indicates the most advanced level of guidance. If *n* is omitted, the default is 4.

Default

OFF	You do not receive guidance about how to improve optimizations for data transformation.

Description

This option lets you set a level of guidance for data transformation. It causes the compiler to generate messages suggesting ways to improve that optimization.

IDE Equivalent

None

Alternate Options

None

See Also

guide, Qguide compiler option
guide-par, Qguide-par compiler option
guide-vec, Qguide-vec compiler option
guide-file, Qguide-file compiler option

guide-file, Qguide-file

Causes the results of guided auto parallelism to be output to a file.

Syntax

Linux OS and macOS:

`-guide-file[=filename]`

Windows OS:

`/Qguide-file[:filename]`

Arguments

filename	Is the name of the file for output. It can include a path.

Default

OFF	Messages that are generated by guided auto parallelism are output to stderr.

Description

This option causes the results of guided auto parallelism to be output to a file.

This option is ignored unless you also specify one or more of the following options:

- `[Q]guide`
- `[Q]guide-vec`
- `[Q]guide-data-trans`
- `[Q]guide-par`

If you do not specify a path, the file is placed in the current working directory.

If there is already a file named *filename*, it will be overwritten.

You can include a file extension in *filename*. For example, if *file.txt* is specified, the name of the output file is *file.txt*. If you do not provide a file extension, the name of the file is *filename.guide*.

If you do not specify *filename*, the name of the file is *name-of-the-first-source-file.guide*. This is also the name of the file if the name specified for *filename* conflicts with a source file name provided in the command line.

NOTE
If you specify the `[Q]guide-file` option and you also specify option `[Q]guide-file-append`, the last option specified on the command line takes precedence.

IDE Equivalent

Visual Studio: **Diagnostics > Guided Auto Parallelism > Emit Guided Auto Parallelism Diagnostics to File**

Diagnostics > Guided Auto Parallelism Diagnostics File

Eclipse: None

Xcode: **Diagnostics > Emit Guided Auto Parallelism diagnostics to File**

Diagnostics > Guided Auto Parallelism Report File

Alternate Options

None

Example

The following example shows how to cause guided auto parallelism messages to be output to a file named *my_guided_autopar.guide*:

```
-guide-file=my_guided_autopar       ! Linux and macOS* systems
/Qguide-file:my_guided_autopar      ! Windows systems
```

See Also

`guide, Qguide` compiler option

`guide-file-append, Qguide-file-append` compiler option

guide-file-append, Qguide-file-append

Causes the results of guided auto parallelism to be appended to a file.

Syntax

Linux OS and macOS:

`-guide-file-append[=`*filename*`]`

Windows OS:

`/Qguide-file-append[:`*filename*`]`

Arguments

filename	Is the name of the file to be appended to. It can include a path.

Default

OFF	Messages that are generated by guided auto parallelism are output to stderr.

Description

This option causes the results of guided auto parallelism to be appended to a file.

This option is ignored unless you also specify one or more of the following options:

- `[Q]guide`
- `[Q]guide-vec`
- `[Q]guide-data-trans`
- `[Q]guide-par`

If you do not specify a path, the compiler looks for *filename* in the current working directory.

If *filename* is not found, then a new file with that name is created in the current working directory.

If you do not specify a file extension, the name of the file is *filename.guide*.

If the name specified for *filename* conflicts with a source file name provided in the command line, the name of the file is *name-of-the-first-source-file.guide*.

NOTE
If you specify the `[Q]guide-file-append` option and you also specify option `[Q]guide-file`, the last option specified on the command line takes precedence.

IDE Equivalent

None

Alternate Options

None

Example

The following example shows how to cause guided auto parallelism messages to be appended to a file named *my_messages.txt*:

```
-guide-file-append=my_messages.txt       ! Linux and macOS* systems
/Qguide-file-append:my_messages.txt      ! Windows systems
```

See Also

`guide, Qguide` compiler option

`guide-file, Qguide-file` compiler option

guide-opts, Qguide-opts

Tells the compiler to analyze certain code and generate recommendations that may improve optimizations.

Syntax

Linux OS and macOS:

`-guide-opts=`*`string`*

Windows OS:

`/Qguide-opts:`*`string`*

Arguments

string

Is the text denoting the code to analyze. The string must appear within quotes. It can take one or more of the following forms:

filename
filename, *routine*
filename, *range* [, *range*]...
filename, *routine*, *range* [, *range*]...

If you specify more than one of the above forms in a string, a semicolon must appear between each form. If you specify more than one *range* in a string, a comma must appear between each *range*. Optional blanks can follow each parameter in the forms above and they can also follow each form in a string.

filename

Specifies the name of a file to be analyzed. It can include a path.

If you do not specify a path, the compiler looks for filename in the current working directory.

routine	Specifies the name of a routine to be analyzed. You can include an identifying argument. The name, including any argument, must be enclosed in single quotes. The compiler tries to uniquely identify the routine that corresponds to the specified routine name. It may select multiple routines to analyze, especially if the following is true: • More than one routine has the specified routine name, so the routine cannot be uniquely identified. • No argument information has been specified to narrow the number of routines selected as matches.
range	Specifies a range of line numbers to analyze in the file or routine specified. The *range* must be specified in integers in the form: *first_line_number-last_line_number* The hyphen between the line numbers is required.

Default

OFF	You do not receive guidance on how to improve optimizations. However, if you specify the `[Q]guide` option, the compiler analyzes and generates recommendations for all the code in an application

Description

This option tells the compiler to analyze certain code and generate recommendations that may improve optimizations.

This option is ignored unless you also specify one or more of the following options:

- `[Q]guide`
- `[Q]guide-vec`
- `[Q]guide-data-trans`
- `[Q]guide-par`

When the `[Q]guide-opts` option is specified, a message is output that includes which parts of the input files are being analyzed. If a routine is selected to be analyzed, the complete routine name will appear in the generated message.

When inlining is involved, you should specify callee line numbers. Generated messages also use callee line numbers.

IDE Equivalent

Visual Studio: **Diagnostics > Guided Auto Parallelism > Guided Auto Parallelism Code Selection Options**

Eclipse: None

Xcode: **Diagnostics > Guided Auto Parallelism Code Selection**

Alternate Options

None

Example

Consider the following:

```
Linux*: -guide-opts="m.f, 1-10; m2.f90, 1-40, 50-90, 100-200; m5.f, 300-400; x.f, 'funca(j)',
22-44, 55-77, 88-99; y.f, 'subrb'"
```

```
Windows*: /Quide-opts="m.f, 1-10; m2.f90, 1-40, 50-90, 100-200; m5.f, 300-400; x.f, 'funca(j)',
22-44, 55-77, 88-99; y.f, 'subrb'"
```

The above command causes the following to be analyzed:

file m.f, line numbers 1 to 10
file m2.f90, line numbers 1 to 40, 50 to 90, and 100 to 200
file m5.f, line numbers 300 to 400
file x.f, function funca with argument (j), line numbers 22 to 44, 55 to 77, and 88 to 99
file y.f, subroutine subrb

guide-par, Qguide-par

Lets you set a level of guidance for auto parallelism.

Syntax

Linux OS and macOS:

`-guide-par[=n]`

Windows OS:

`/Qguide-par[:n]`

Arguments

n	Is an optional value specifying the level of guidance to be provided. The values available are 1 through 4. Value 1 indicates a standard level of guidance. Value 4 indicates the most advanced level of guidance. If *n* is omitted, the default is 4.

Default

OFF	You do not receive guidance about how to improve optimizations for parallelism.

Description

This option lets you set a level of guidance for auto parallelism. It causes the compiler to generate messages suggesting ways to improve that optimization.

You must also specify the `[Q]parallel` option to receive auto parallelism guidance.

IDE Equivalent

None

Alternate Options

heap-arrays

Puts automatic arrays and arrays created for temporary computations on the heap instead of the stack.

Syntax

Linux OS and macOS:

`-heap-arrays [size]`

`-no-heap-arrays`

Windows OS:

`/heap-arrays[:size]`

`/heap-arrays-`

Arguments

size	Is an integer value representing the size of the arrays in kilobytes. Arrays smaller than *size* are put on the stack.

Default

`-no-heap-arrays` The compiler puts automatic arrays and temporary arrays in the stack storage area.

or
`/heap-arrays-`

Description

This option puts automatic arrays and arrays created for temporary computations on the heap instead of the stack.

When this option is specified, automatic (temporary) arrays that have a compile-time size greater than the value specified for *size* are put on the heap, rather than on the stack. If the compiler cannot determine the size at compile time, it always puts the automatic array on the heap.

If *size* is specified, the value is only used when the total size of the temporary array or automatic array can be determined at compile time, using compile-time constants. Any arrays known at compile-time to be larger than *size* are allocated on the heap instead of the stack. For example, if 10 is specified for *size*:

- All automatic and temporary arrays equal to or larger than 10 KB are put on the heap.
- All automatic and temporary arrays smaller than 10 KB are put on the stack.

If *size* is omitted, and the size of the temporary array or automatic array cannot be determined at compile time, it is assumed that the total size is greater than *size* and the array is allocated on the heap.

On Windows, you can use compiler option `/F` to tell the linker to increase the size of the run-time stack to allow for large objects on the stack.

On Linux and macOS*, you can use the shell command `unlimit` to increase the size of the run-time stack before execution.

IDE Equivalent

Visual Studio: **Optimization > Heap Arrays**

Eclipse: None

Xcode: **Data > Allocate Automatics to the Heap**

Alternate Options

None

Example

In Fortran, an automatic array gets its size from a run-time expression. For example:

```
RECURSIVE SUBROUTINE F( N )
INTEGER :: N
REAL :: X ( N )     ! an automatic array
REAL :: Y ( 1000 )  ! an explicit-shape local array on the stack
```

Array X in the example above is affected by the `heap-array` option; array Y is not.

Temporary arrays are often created before making a routine call, or when an array operation detects overlap. For example:

```
integer a(10000)
a(2:) = a(1:ubound(a,dim=1)-1)
```

In this case, the array assignment uses a temporary intermediate array because there is clearly an overlap between the right hand side and the left hand side of the assignment.

If you specify the `heap-arrays` option, the compiler creates the temporary array on the heap.

If you specify the `heap-arrays` option with *size* 50, the compiler creates the temporary array on the stack. This is because the size of the temporary intermediate array can be determined at compile time (40Kb), and it's size is less than the *size* value.

In the following example, a contiguous array is created from the array slice declaration and passed on:

```
call somesub(a(1:10000:2))
```

If you specify the `heap-arrays` option, the compiler creates the temporary array on the heap.

If you specify the `heap-arrays` option with *size* 25, the compiler creates the temporary array on the stack. This is because the size of the temporary intermediate array at compile time is only 20Kb.

See Also

`F` compiler option

mkl, Qmkl

Tells the compiler to link to certain libraries in the Intel® Math Kernel Library (Intel® MKL). On Windows systems, you must specify this option at compile time.

Syntax

Linux OS:

`-mkl[=lib]`

macOS:

`-mkl[=lib]`

Windows OS:

`/Qmkl[:lib]`

Arguments

lib	Indicates which Intel® MKL library files should be linked. Possible values are:	
	`parallel`	Tells the compiler to link using the threaded libraries in the Intel® MKL. This is the default if the option is specified with no *lib*.
	`sequential`	Tells the compiler to link using the sequential libraries in the Intel® MKL.
	`cluster`	Tells the compiler to link using the cluster-specific libraries and the sequential libraries in the Intel® MKL. Cluster-specific libraries are not available for macOS*.

Default

OFF	The compiler does not link to the Intel® MKL.

Description

This option tells the compiler to link to certain libraries in the Intel® Math Kernel Library (Intel® MKL).

On Linux* and macOS* systems, dynamic linking is the default when you specify `-mkl`. To link with Intel® MKL statically, you must specify:

```
-mkl -static-intel
```

On Windows* systems, static linking is the default when you specify `/Qmkl`. To link with Intel® MKL dynamically, you must specify:

```
/Qmkl /libs:dll or /Qmkl /MD
```

For more information about using MKL libraries, see the article in Intel® Developer Zone titled: *Intel® Math Kernel Library Link Line Advisor*, which is located in https://software.intel.com/en-us/articles/intel-mkl-link-line-advisor .

NOTE
On Windows* systems, this option adds directives to the compiled code, which the linker then reads without further input from the driver. On Linux* and macOS* systems, the driver must add the library names explicitly to the link command.

IDE Equivalent

Visual Studio: **Libraries > Use Intel(R) Math Kernel Library**

Eclipse: None

Xcode: **Libraries > Use Intel(R) Math Kernel Library**

Alternate Options

None

See Also

`static-intel` compiler option
`MD` compiler option
`libs` compiler option

pad, Qpad

Enables the changing of the variable and array memory layout.

Syntax

Linux OS and macOS:

`-pad`

`-nopad`

Windows OS:

`/Qpad`

`/Qpad-`

Arguments

None

Default

`-nopad` Variable and array memory layout is performed by default methods.
or `/Qpad-`

Description

This option enables the changing of the variable and array memory layout.

This option is effectively not different from the `align` option when applied to structures and derived types. However, the scope of `pad` is greater because it applies also to common blocks, derived types, sequence types, and structures.

IDE Equivalent

None

Alternate Options

None

See Also

`align` compiler option

qopt-args-in-regs, Qopt-args-in-regs

Determines whether calls to routines are optimized by passing arguments in registers instead of on the stack.

Architecture Restrictions

Only available on IA-32 architecture

Syntax

Linux OS:

`-qopt-args-in-regs[=keyword]`

macOS:

`None`

Windows OS:

`/Qopt-args-in-regs[:keyword]`

Arguments

keyword Specifies whether the optimization should be performed and under what conditions. Possible values are:

`none`	The optimization is not performed. No arguments are passed in registers. They are put on the stack.
`seen`	Causes arguments to be passed in registers when they are passed to routines whose definition can be seen in the same compilation unit.
`all`	Causes arguments to be passed in registers, whether they are passed to routines whose definition can be seen in the same compilation unit, or not. This value is only available on Linux* systems.

Default

`-qopt-args-in-regs=seen` or `/Qopt-args-in-regs:seen` Arguments are passed in registers when they are passed to routines whose definition is seen in the same compilation unit.

Description

This option determines whether calls to routines are optimized by passing arguments in registers instead of on the stack. It also indicates the conditions when the optimization will be performed.

This option can improve performance for Application Binary Interfaces (ABIs) that require arguments to be passed in memory and compiled without interprocedural optimization (IPO).

Note that on Linux* systems, if `all` is specified, a small overhead may be paid when calling "unseen" routines that have not been compiled with the same option. This is because the call will need to go through a "thunk" to ensure that arguments are placed back on the stack where the callee expects them.

IDE Equivalent

None

Alternate Options

None

qopt-assume-safe-padding, Qopt-assume-safe-padding

Determines whether the compiler assumes that variables and dynamically allocated memory are padded past the end of the object.

Architecture Restrictions

Only available on all architectures that support Intel® Advanced Vector Extensions 512 (Intel® AVX-512) Foundation instructions

Syntax

Linux OS and macOS:

`-qopt-assume-safe-padding`

`-qno-opt-assume-safe-padding`

Windows OS:

`/Qopt-assume-safe-padding`

`/Qopt-assume-safe-padding-`

Arguments

None

Default

`-qno-opt-assume-safe-padding` or `/Qopt-assume-safe-padding-`	The compiler will not assume that variables and dynamically allocated memory are padded past the end of the object. It will adhere to the sizes specified in your program.

Description

This option determines whether the compiler assumes that variables and dynamically allocated memory are padded past the end of the object.

When you specify option `[q or Q]opt-assume-safe-padding`, the compiler assumes that variables and dynamically allocated memory are padded. This means that code can access up to 64 bytes beyond what is specified in your program.

The compiler does not add any padding for static and automatic objects when this option is used, but it assumes that code can access up to 64 bytes beyond the end of the object, wherever the object appears in the program. To satisfy this assumption, you must increase the size of static and automatic objects in your program when you use this option.

This option may improve performance of memory operations.

IDE Equivalent

None

Alternate Options

None

qopt-block-factor, Qopt-block-factor

Lets you specify a loop blocking factor.

Syntax

Linux OS and macOS:

`-qopt-block-factor=n`

Windows OS:

`/Qopt-block-factor:n`

Arguments

n	Is the blocking factor. It must be an integer. The compiler may ignore the blocking factor if the value is 0 or 1.

Default

OFF	The compiler uses default heuristics for loop blocking.

Description

This option lets you specify a loop blocking factor.

IDE Equivalent

None

Alternate Options

None

qopt-dynamic-align, Qopt-dynamic-align

Enables or disables dynamic data alignment optimizations.

Syntax

Linux OS and macOS:

`-qopt-dynamic-align`

`-qno-opt-dynamic-align`

Windows OS:

`/Qopt-dynamic-align`

`/Qopt-dynamic-align-`

Arguments

None

Default

`-qopt-dynamic-align` or `/Qopt-dynamic-align`	The compiler may generate code dynamically dependent on alignment. It may do optimizations based on data location for the best performance. The result of execution on some algorithms may depend on data layout.

Description

This option enables or disables dynamic data alignment optimizations.

If you specify `-qno-opt-dynamic-align` or `/Qopt-dynamic-align-`, the compiler generates no code dynamically dependent on alignment. It will not do any optimizations based on data location and results will depend on the data values themselves.

When you specify `[q or Q]qopt-dynamic-align`, the compiler may implement conditional optimizations based on dynamic alignment of the input data. These dynamic alignment optimizations may result in different bitwise results for aligned and unaligned data with the same values.

Dynamic alignment optimizations can improve the performance of vectorized code, especially for long trip count loops. Disabling such optimizations can decrease performance, but it may improve bitwise reproducibility of results, factoring out data location from possible sources of discrepancy.

IDE Equivalent

None

Alternate Options

None

qopt-jump-tables, Qopt-jump-tables

Enables or disables generation of jump tables for switch statements.

Syntax

Linux OS and macOS:

`-qopt-jump-tables=`*keyword*

`-qno-opt-jump-tables`

Windows OS:

`/Qopt-jump-tables:`*keyword*

`/Qopt-jump-tables-`

Arguments

keyword

Is the instruction for generating jump tables. Possible values are:

`never`	Tells the compiler to never generate jump tables. All switch statements are implemented as chains of if-then-elses. This is the same as specifying `-qno-opt-jump-tables` (Linux* and macOS*) or `/Qopt-jump-tables-` (Windows*).

`default`	The compiler uses default heuristics to determine when to generate jump tables.
`large`	Tells the compiler to generate jump tables up to a certain pre-defined size (64K entries).
`n`	Must be an integer. Tells the compiler to generate jump tables up to *n* entries in size.

Default

`-qopt-jump-tables=default` or `/Qopt-jump-tables:default`	The compiler uses default heuristics to determine when to generate jump tables for switch statements.

Description

This option enables or disables generation of jump tables for switch statements. When the option is enabled, it may improve performance for programs with large switch statements.

IDE Equivalent

None

Alternate Options

None

qopt-malloc-options

Lets you specify an alternate algorithm for malloc().

Syntax

Linux OS and macOS:

`-qopt-malloc-options=`*n*

Windows OS:

`None`

Arguments

n

Specifies the algorithm to use for malloc(). Possible values are:

`0`	Tells the compiler to use the default algorithm for malloc(). This is the default.
`1`	Causes the following adjustments to the malloc() algorithm: M_MMAP_MAX=2 and M_TRIM_THRESHOLD=0x10000000.
`2`	Causes the following adjustments to the malloc() algorithm: M_MMAP_MAX=2 and M_TRIM_THRESHOLD=0x40000000.
`3`	Causes the following adjustments to the malloc() algorithm: M_MMAP_MAX=0 and M_TRIM_THRESHOLD=-1.

4	Causes the following adjustments to the malloc() algorithm: M_MMAP_MAX=0, M_TRIM_THRESHOLD=-1, M_TOP_PAD=4096.

Default

`-qopt-malloc-options=0`	The compiler uses the default algorithm when malloc() is called. No call is made to mallopt().

Description

This option lets you specify an alternate algorithm for malloc().

If you specify a non-zero value for *n*, it causes alternate configuration parameters to be set for how malloc() allocates and frees memory. It tells the compiler to insert calls to mallopt() to adjust these parameters to malloc() for dynamic memory allocation. This may improve speed.

IDE Equivalent

None

Alternate Options

None

malloc(3) man page

mallopt function (defined in malloc.h)

qopt-matmul, Qopt-matmul

Enables or disables a compiler-generated Matrix Multiply (matmul) library call.

Syntax

Linux OS:

`-qopt-matmul`

`-qno-opt-matmul`

macOS:

`None`

Windows OS:

`/Qopt-matmul`

`/Qopt-matmul-`

Arguments

None

Default

`-qno-opt-matmul` or `/Qopt-matmul-`	The matmul library call optimization does not occur unless this option is enabled or certain other compiler options are specified (see below).

Description

This option enables or disables a compiler-generated Matrix Multiply (MATMUL) library call.

The `[q or Q]opt-matmul` option tells the compiler to identify matrix multiplication loop nests (if any) and replace them with a matmul library call for improved performance. The resulting executable may get additional performance gain on Intel® microprocessors than on non-Intel microprocessors.

> **NOTE**
> This option is dependent upon the OpenMP* library. If your product does not support OpenMP, this option will have no effect.

This option is enabled by default if options `O3` and `[Q]parallel` are specified. To disable this optimization, specify `-qno-opt-matmul` or `/Qopt-matmul-`.

This option has no effect unless option `O2` or higher is set.

> **NOTE**
> Many routines in the MATMUL library are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

IDE Equivalent

Visual Studio: **Optimization > Enable Matrix Multiply Library Call**

Eclipse: None

Xcode: None

Alternate Options

None

- `O` compiler option

qopt-mem-layout-trans, Qopt-mem-layout-trans

Controls the level of memory layout transformations performed by the compiler.

Syntax

Linux OS and macOS:

`-qopt-mem-layout-trans[=n]`

`-qno-opt-mem-layout-trans`

Windows OS:

`/Qopt-mem-layout-trans[:n]`

`/Qopt-mem-layout-trans-`

Arguments

n	Is the level of memory layout transformations. Possible values are:

`0`	Disables memory layout transformations. This is the same as specifying `-qno-opt-mem-layout-trans` (Linux* and macOS*) or `/Qopt-mem-layout-trans-` (Windows*).
`1`	Enables basic memory layout transformations.
`2`	Enables more memory layout transformations. This is the same as specifying `[q or Q]opt-mem-layout-trans` with no argument.
`3`	Enables more memory layout transformations like copy-in/copy-out of structures for a region of code. You should only use this setting if your system has more than 4GB of physical memory per core.
`4`	Enables more aggressive memory layout transformations. You should only use this setting if your system has more than 4GB of physical memory per core.

Default

`-qopt-mem-layout-trans=2` The compiler performs moderate memory layout transformations.

or
`/Qopt-mem-layout-trans:2`

Description

This option controls the level of memory layout transformations performed by the compiler. This option can improve cache reuse and cache locality.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

IDE Equivalent

None

Alternate Options

None

qopt-multi-version-aggressive, Qopt-multi-version-aggressive

Tells the compiler to use aggressive multi-versioning to check for pointer aliasing and scalar replacement.

Syntax

Linux OS and macOS:

`-qopt-multi-version-aggressive`

`-qno-opt-multi-version-aggressive`

Windows OS:

`/Qopt-multi-version-aggressive`

`/Qopt-multi-version-aggressive-`

Arguments

None

Default

`-qno-opt-multi-version-aggressive` or `/Qopt-multi-version-aggressive-`	The compiler uses default heuristics when checking for pointer aliasing and scalar replacement.

Description

This option tells the compiler to use aggressive multi-versioning to check for pointer aliasing and scalar replacement. This option may improve performance.

The performance can be affected by certain options, such as `/arch` or `/Qx` (Windows*) or `-m` or `-x` (Linux* and macOS*).

IDE Equivalent

None

Alternate Options

None

qopt-prefetch, Qopt-prefetch

Enables or disables prefetch insertion optimization.

Syntax

Linux OS and macOS:

`-qopt-prefetch[=`*n*`]`

`-qno-opt-prefetch`

Windows OS:

`/Qopt-prefetch[:`*n*`]`

`/Qopt-prefetch-`

Arguments

n	Is the level of software prefetching optimization desired. Possible values are:
`0`	Disables software prefetching. This is the same as specifying `-qno-opt-prefetch` (Linux* and macOS*) or `/Qopt-prefetch-` (Windows*).
`1` to `5`	Enables different levels of software prefetching. If you do not specify a value for *n*, the default is `2`. Use lower values to reduce the amount of prefetching.

Default

`-qno-opt-prefetch` or `/Qopt-prefetch-`	Prefetch insertion optimization is disabled.

Description

This option enables or disables prefetch insertion optimization. The goal of prefetching is to reduce cache misses by providing hints to the processor about when data should be loaded into the cache.

This option enables prefetching when higher optimization levels are specified.

IDE Equivalent

Visual Studio: **Optimization > Prefetch Insertion**

Eclipse: None

Xcode: **Optimization > Enable Prefetch Insertion**

Alternate Options

None

See Also

qopt-prefetch-distance, Qopt-prefetch-distance compiler option

qopt-prefetch-distance, Qopt-prefetch-distance

Specifies the prefetch distance to be used for compiler-generated prefetches inside loops.

Syntax

Linux OS:

`-qopt-prefetch-distance=`*n1*`[, `*n2*`]`

macOS:

`None`

Windows OS:

`/Qopt-prefetch-distance:`*n1*`[, `*n2*`]`

Arguments

n1, n2	Is the prefetch distance in terms of the number of (possibly-vectorized) iterations. Possible values are non-negative numbers >=0. *n2* is optional. *n1* = 0 turns off all compiler issued prefetches from memory to L2. *n2* = 0 turns off all compiler issued prefetches from L2 to L1. If *n2* is specified and *n1* > 0, *n1* should be >= *n2*.

Default

OFF	The compiler uses default heuristics to determine the prefetch distance.

Description

This option specifies the prefetch distance to be used for compiler-generated prefetches inside loops. The unit (*n1* and optionally *n2*) is the number of iterations. If the loop is vectorized by the compiler, the unit is the number of vectorized iterations.

The value of *n1* will be used as the distance for prefetches from memory to L2 (for example, the vprefetch1 instruction). If *n2* is specified, it will be used as the distance for prefetches from L2 to L1 (for example, the vprefetch0 instruction).

This option is ignored if option `-qopt-prefetch=0` (Linux*) or `/Qopt-prefetch:0` (Windows*) is specified.

IDE Equivalent

None

Alternate Options

None

Example

Consider the following Linux* examples:

```
-qopt-prefetch-distance=64,32
```

The above causes the compiler to use a distance of 64 iterations for memory to L2 prefetches, and a distance of 32 iterations for L2 to L1 prefetches.

```
-qopt-prefetch-distance=24
```

The above causes the compiler to use a distance of 24 iterations for memory to L2 prefetches. The distance for L2 to L1 prefetches will be determined by the compiler.

```
-qopt-prefetch-distance=0,4
```

The above turns off all memory to L2 prefetches inserted by the compiler inside loops. The compiler will use a distance of 4 iterations for L2 to L1 prefetches.

```
-qopt-prefetch-distance=16,0
```

The above causes the compiler to use a distance of 16 iterations for memory to L2 prefetches. No L2 to L1 loop prefetches are issued by the compiler.

See Also

qopt-prefetch, Qopt-prefetch compiler option
PREFETCH directive

qopt-prefetch-issue-excl-hint, Qopt-prefetch-issue-excl-hint

Supports the prefetchW instruction in Intel® microarchitecture code name Broadwell and later.

Syntax

Linux OS:

`-qopt-prefetch-issue-excl-hint`

macOS:

`None`

Windows OS:

`/Qopt-prefetch-issue-excl-hint`

Arguments

None

Default

OFF	The compiler does not support the PREFETCHW instruction for this microarchitecture.

Description

This option supports the PREFETCHW instruction in Intel® microarchitecture code name Broadwell and later.

When you specify this option, you must also specify option `[q or Q]opt-prefetch`.

The prefetch instruction is merely a hint and does not affect program behavior. If executed, this instruction moves data closer to the processor and invalidates any other cached copy in anticipation of the line being written to in the future.

IDE Equivalent

None

Alternate Options

None

See Also

`qopt-prefetch/Qopt-prefetch` compiler option

qopt-ra-region-strategy, Qopt-ra-region-strategy

Selects the method that the register allocator uses to partition each routine into regions.

Syntax

Linux OS and macOS:

`-qopt-ra-region-strategy[=`*keyword*`]`

Windows OS:

`/Qopt-ra-region-strategy[:`*keyword*`]`

Arguments

keyword Is the method used for partitioning. Possible values are:

`routine`	Creates a single region for each routine.
`block`	Partitions each routine into one region per basic block.
`trace`	Partitions each routine into one region per trace.
`loop`	Partitions each routine into one region per loop.
`default`	The compiler determines which method is used for partitioning.

Default

`-qopt-ra-region-strategy=default` or `/Qopt-ra-region-strategy:default`

The compiler determines which method is used for partitioning. This is also the default if `keyword` is not specified.

Description

This option selects the method that the register allocator uses to partition each routine into regions.

When setting `default` is in effect, the compiler attempts to optimize the tradeoff between compile-time performance and generated code performance.

This option is only relevant when optimizations are enabled (option `O1` or higher).

IDE Equivalent

None

Alternate Options

None

- `O` compiler option

qopt-streaming-stores, Qopt-streaming-stores

Enables generation of streaming stores for optimization.

Syntax

Linux OS and macOS:

`-qopt-streaming-stores=`*keyword*

Windows OS:

`/Qopt-streaming-stores:`*keyword*

Arguments

keyword Specifies whether streaming stores are generated. Possible values are:

`always`	Enables generation of streaming stores for optimization. The compiler optimizes under the assumption that the application is memory bound. When this option setting is specified, it is your responsibility to also insert any memory barriers (fences) as required to ensure correct memory ordering within a thread or across threads. See the Examples section for one way to do this.
`never`	Disables generation of streaming stores for optimization. Normal stores are performed.
`auto`	Lets the compiler decide which instructions to use.

Default

`-qopt-streaming-stores=auto` or `/Qopt-streaming-stores:auto`	The compiler decides whether to use streaming stores or normal stores.

Description

This option enables generation of streaming stores for optimization. This method stores data with instructions that use a non-temporal buffer, which minimizes memory hierarchy pollution.

This option may be useful for applications that can benefit from streaming stores.

IDE Equivalent

None

Alternate Options

None

Example

The following example shows one way to insert memory barriers (fences) when specifying `-qopt-streaming-stores=always` or `/Qopt-streaming-stores:always`. It uses the procedure interface for_sfence from the module IFCORE, which maps to the C/C++ function _mm_sfence:

```
subroutine sub1(a, b, c, len, n1, n2)
use IFCORE, only : for_sfence
integer len, n1, n2, i, j
real(8) a(len), b(len), c(len), d(len)

  !$omp parallel do
  do j = 1, n1
     a(j) = 1.0
     b(j) = 2.0
     c(j) = 3.0
  enddo
  !$omp end parallel do

call ftn_sfence()

  !$omp parallel do
```

```
  do i = 1, n2
     a(i) = a(i) + b(i) * c(i)
  enddo
  !$omp end parallel do

end
```

ax, Qax compiler option

x, Qx compiler option

qopt-subscript-in-range, Qopt-subscript-in-range

Determines whether the compiler assumes that there are no "large" integers being used or being computed inside loops.

Syntax

Linux OS and macOS:

`-qopt-subscript-in-range`

`-qno-opt-subscript-in-range`

Windows OS:

`/Qopt-subscript-in-range`

`/Qopt-subscript-in-range-`

Arguments

None

Default

`-qno-opt-subscript-in-range` or `/Qopt-subscript-in-range-`	The compiler assumes there are "large" integers being used or being computed within loops.

Description

This option determines whether the compiler assumes that there are no "large" integers being used or being computed inside loops.

If you specify `[q or Q]opt-subscript-in-range`, the compiler assumes that there are no "large" integers being used or being computed inside loops. A "large" integer is typically > 2^{31}.

This feature can enable more loop transformations.

IDE Equivalent

None

Alternate Options

None

Example

The following example shows how these options can be useful. Variable m is declared as type integer(kind=8) (64-bits) and all other variables inside the subscript are declared as type integer(kind=4) (32-bits):

```
A[ i  + j  + ( n  + k) * m ]
```

qopt-zmm-usage, Qopt-zmm-usage

Defines a level of zmm registers usage.

Syntax

Linux OS and macOS:

`-qopt-zmm-usage=`*keyword*

Windows OS:

`/Qopt-zmm-usage:`*keyword*

Arguments

keyword	Specifies the level of zmm registers usage. Possible values are:	
	`low`	Tells the compiler that the compiled program is unlikely to benefit from zmm registers usage. It specifies that the compiler should avoid using zmm registers unless it can prove the gain from their usage.
	`high`	Tells the compiler to generate zmm code without restrictions.

Default

varies	The default is low when you specify [Q]xCORE-AVX512. The default is high when you specify [Q]xCOMMON-AVX512.

Description

This option may provide better code optimization for Intel® processors that are on the Intel® microarchitecture formerly code-named Skylake.

This option defines a level of zmm registers usage. The `low` setting causes the compiler to generate code with zmm registers very carefully, only when the gain from their usage is proven. The `high` setting causes the compiler to use much less restrictive heuristics for zmm code generation.

It is not always easy to predict whether the `high` or the `low` setting will yield better performance. Programs that enjoy high performance gains from the use of xmm or ymm registers may expect performance improvement by moving to use zmm registers. However, some programs that use zmm registers may not gain as much or may even lose performance. We recommend that you try both option values to measure the performance of your programs.

This option is ignored if you do not specify an option that enables Intel® AVX-512, such as `[Q]xCORE-AVX512` or option `[Q]xCOMMON-AVX512`.

This option has no effect on loops that use directive SIMD SIMDLEN(n) or on functions that are generated by vector specifications specific to CORE-AVX512.

IDE Equivalent

None

Alternate Options

None

See Also

`x, Qx` compiler option
SIMD Directive (OpenMP* API) clause SIMDLEN

qoverride-limits, Qoverride-limits

Lets you override certain internal compiler limits that are intended to prevent excessive memory usage or compile times for very large, complex compilation units.

Syntax

Linux OS and macOS:

`-qoverride-limits`

Windows OS:

`/Qoverride-limits`

Arguments

None

Default

OFF	Certain internal compiler limits are not overridden. These limits are determined by default heuristics.

Description

This option provides a way to override certain internal compiler limits that are intended to prevent excessive memory usage or compile times for very large, complex compilation units.

If this option is not used and your program exceeds one of these internal compiler limits, some optimizations will be skipped to reduce the memory footprint and compile time. If you chose to create an optimization report by specifying `[q or Q]opt-report`, you may see a related diagnostic remark as part of the report.

Specifying this option may substantially increase compile time and/or memory usage.

NOTE
If you use this option, it is your responsibility to ensure that sufficient memory is available. If there is not sufficient available memory, the compilation may fail.

This option should only be used where there is a specific need; it is not recommended for inexperienced users.

IDE Equivalent

None

Alternate Options

None

reentrancy

Tells the compiler to generate reentrant code to support a multithreaded application.

Syntax

Linux OS and macOS:

`-reentrancy` *`keyword`*

`-noreentrancy`

Windows OS:

`/reentrancy:`*`keyword`*

`/noreentrancy`

Arguments

`keyword` Specifies details about the program. Possible values are:

`none`	Tells the run-time library (RTL) that the program does not rely on threaded or asynchronous reentrancy. The RTL will not guard against such interrupts inside its own critical regions. This is the same as specifying noreentrancy.
`async`	Tells the run-time library (RTL) that the program may contain asynchronous (AST) handlers that could call the RTL. This causes the RTL to guard against AST interrupts inside its own critical regions.
`threaded`	Tells the run-time library (RTL) that the program is multithreaded, such as programs using the POSIX threads library. This causes the RTL to use thread locking to guard its own critical regions.

Default

`threaded` The compiler tells the run-time library (RTL) that the program is multithreaded.

Description

This option tells the compiler to generate reentrant code to support a multithreaded application.

If you do not specify a keyword for reentrancy, it is the same as specifying `reentrancy threaded`.

To ensure that a threadsafe and/or reentrant run-time library is linked and correctly initialized, option `reentrancy threaded` should also be used for the link step and for the compilation of the main routine.

Note that if option threads is specified, it sets option `reentrancy threaded`, since multithreaded code must be reentrant.

IDE Equivalent

Visual Studio: **Code Generation > Generate Reentrant Code**

Eclipse: None

Xcode: **Code Generation > Generate Reentrant Code**

Alternate Options

None

See Also

`threads` compiler option

safe-cray-ptr, Qsafe-cray-ptr

Tells the compiler that Cray pointers do not alias other variables.*

Syntax

Linux OS and macOS:

`-safe-cray-ptr`

Windows OS:

`/Qsafe-cray-ptr`

Arguments

None

Default

OFF The compiler assumes that Cray pointers alias other variables.

Description

This option tells the compiler that Cray pointers do not alias (that is, do not specify sharing memory with) other variables.

IDE Equivalent

Visual Studio: **Data > Assume CRAY Pointers Do Not Share Memory Locations** (/Qsafe-cray-ptr)

Eclipse: None

Xcode: **Data > Assume Cray Pointers Do Not Share Memory Locations**

Alternate Options

None

Example

Consider the following:

```
pointer (pb, b)
pb = getstorage()
do i = 1, n
b(i) = a(i) + 1
enddo
```

By default, the compiler assumes that b and a are aliased. To prevent such an assumption, specify the `-safe-cray-ptr` (Linux* and macOS*) or `/Qsafe-cray-ptr` (Windows*) option, and the compiler will treat b(i) and a(i) as independent of each other.

However, if the variables are intended to be aliased with Cray pointers, using the option produces incorrect results. In the following example, you should not use the option:

```
pointer (pb, b)
pb = loc(a(2))
do i=1, n
b(i) = a(i) +1
enddo
```

scalar-rep, Qscalar-rep

Enables or disables the scalar replacement optimization done by the compiler as part of loop transformations.

Syntax

Linux OS and macOS:

`-scalar-rep`

`-no-scalar-rep`

Windows OS:

`/Qscalar-rep`

`/Qscalar-rep-`

Arguments

None

Default

`-scalar-rep` or `/Qscalar-rep`	Scalar replacement is performed during loop transformation at optimization levels of O2 and above.

Description

This option enables or disables the scalar replacement optimization done by the compiler as part of loop transformations. This option takes effect only if you specify an optimization level of `O2` or higher.

IDE Equivalent

None

Alternate Options

None

See Also

`O` compiler option

simd, Qsimd

Enables or disables compiler interpretation of SIMD directives.

Syntax

Linux OS and macOS:

`-simd`

`-no-simd`

Windows OS:

`/Qsimd`

`/Qsimd-`

Arguments

None

Default

`-simd` or `/Qsimd`	SIMD directives are enabled.

Description

This option enables or disables compiler interpretation of SIMD directives.

To disable interpretation of SIMD directives, specify `-no-simd` (Linux* and macOS*) or `/Qsimd-` (Windows*). Note that the compiler may still vectorize loops based on its own heuristics (leading to generation of SIMD instructions) even when `-no-simd` (or `/Qsimd-`) is specified.

To disable all compiler vectorization, use the "`-no-vec -no-simd`" (Linux* and macOS*) or "`/Qvec- /Qsimd-`" (Windows*) compiler options. The option `-no-vec` (and `/Qvec-`) disables all auto-vectorization, including vectorization of array notation statements. The option `-no-simd` (and `/Qsimd-`) disables vectorization of loops that have SIMD directives.

NOTE
If you specify option `-mia32` (Linux*) or option `/arch:IA32` (Windows*), SIMD directives are disabled by default and vector instructions cannot be used. Therefore, you cannot explicitly enable SIMD directives by specifying option `[Q]simd`.

IDE Equivalent

None

Alternate Options

None

See Also

`vec, Qvec` compiler option
SIMD Directive

unroll, Qunroll

Tells the compiler the maximum number of times to unroll loops.

Syntax

Linux OS:

`-unroll[=n]`

macOS:

`-unroll[=n]`

Windows OS:

`/Qunroll[:n]`

Arguments

n	Is the maximum number of times a loop can be unrolled. To disable loop enrolling, specify 0.

Default

`-unroll` or `/Qunroll` The compiler uses default heuristics when unrolling loops.

Description

This option tells the compiler the maximum number of times to unroll loops.

If you do not specify *n*, the optimizer determines how many times loops can be unrolled.

IDE Equivalent

Visual Studio: **Optimization > Loop Unroll Count**

Eclipse: None

Xcode: **Optimization > Loop Unroll Count**

Alternate Options

Linux and macOS*: `-funroll-loops`

Windows: `/unroll` (this is a deprecated option)

unroll-aggressive, Qunroll-aggressive

Determines whether the compiler uses more aggressive unrolling for certain loops.

Syntax

Linux OS:

`-unroll-aggressive`

`-no-unroll-aggressive`

macOS:

`-unroll-aggressive`

`-no-unroll-aggressive`

Windows OS:

`/Qunroll-aggressive`

`/Qunroll-aggressive-`

Arguments

None

Default

`-no-unroll-aggressive` or `/Qunroll-aggressive-`	The compiler uses default heuristics when unrolling loops.

Description

This option determines whether the compiler uses more aggressive unrolling for certain loops. The positive form of the option may improve performance.

This option enables aggressive, complete unrolling for loops with small constant trip counts.

IDE Equivalent

None

Alternate Options

None

vec, Qvec

Enables or disables vectorization.

Syntax

Linux OS:

`-vec`

`-no-vec`

macOS:

`-vec`

`-no-vec`

Windows OS:

`/Qvec`

`/Qvec-`

Arguments

None

Default

`-vec` or `/Qvec`	Vectorization is enabled if option `O2` or higher is in effect.

Description

This option enables or disables vectorization.

To disable vectorization, specify `-no-vec` (Linux* and macOS*) or `/Qvec-` (Windows*).

To disable interpretation of SIMD directives, specify `-no-simd` (Linux* and macOS*) or `/Qsimd-` (Windows*).

To disable all compiler vectorization, use the "`-no-vec -no-simd`" (Linux* and macOS*) or "`/Qvec- /Qsimd-`" (Windows*) compiler options. The option `-no-vec` (and `/Qvec-`) disables all auto-vectorization, including vectorization of array notation statements. The option `-no-simd` (and `/Qsimd-`) disables vectorization of loops that have SIMD directives.

NOTE
Using this option enables vectorization at default optimization levels for both Intel® microprocessors and non-Intel microprocessors. Vectorization may call library routines that can result in additional performance gain on Intel microprocessors than on non-Intel microprocessors. The vectorization can also be affected by certain options, such as `/arch` (Windows), `-m` (Linux and macOS*), or `[Q]x`.

IDE Equivalent

None

Alternate Options

None

See Also

`simd, Qsimd` compiler option
`ax, Qax` compiler option
`x, Qx` compiler option
`vec-guard-write, Qvec-guard-write` compiler option
`vec-threshold, Qvec-threshold` compiler option

vec-guard-write, Qvec-guard-write

Tells the compiler to perform a conditional check in a vectorized loop.

Syntax

Linux OS and macOS:

`-vec-guard-write`

`-no-vec-guard-write`

Windows OS:

`/Qvec-guard-write`

`/Qvec-guard-write-`

Arguments

None

Default

`-vec-guard-write` or `/Qvec-guard-write`	The compiler performs a conditional check in a vectorized loop.

Description

This option tells the compiler to perform a conditional check in a vectorized loop. This checking avoids unnecessary stores and may improve performance.

IDE Equivalent

None

Alternate Options

None

vec-threshold, Qvec-threshold

Sets a threshold for the vectorization of loops.

Syntax

Linux OS and macOS:

`-vec-threshold[n]`

Windows OS:

`/Qvec-threshold[[:]n]`

Arguments

n	Is an integer whose value is the threshold for the vectorization of loops. Possible values are 0 through 100. If *n* is 0, loops get vectorized always, regardless of computation work volume. If *n* is 100, loops get vectorized when performance gains are predicted based on the compiler analysis data. Loops get vectorized only if profitable vector-level parallel execution is almost certain. The intermediate 1 to 99 values represent the percentage probability for profitable speed-up. For example, *n*=50 directs the compiler to vectorize only if there is a 50% probability of the code speeding up if executed in vector form.

Default

`-vec-threshold100` or `/Qvec-threshold100`	Loops get vectorized only if profitable vector-level parallel execution is almost certain. This is also the default if you do not specify *n*.

Description

This option sets a threshold for the vectorization of loops based on the probability of profitable execution of the vectorized loop in parallel.

This option is useful for loops whose computation work volume cannot be determined at compile-time. The threshold is usually relevant when the loop trip count is unknown at compile-time.

The compiler applies a heuristic that tries to balance the overhead of creating multiple threads versus the amount of work available to be shared amongst the threads.

IDE Equivalent

Visual Studio: **Optimization > Threshold For Vectorization**

Eclipse: None

Xcode: **Optimization > Enable Maximum Vector-level Parallelism**

Alternate Options

None

vecabi, Qvecabi

Determines which vector function application binary interface (ABI) the compiler uses to create or call vector functions.

Syntax

Linux OS:

`-vecabi=`*keyword*

macOS:

`-vecabi=`*keyword*

Windows OS:

`/Qvecabi:`*keyword*

Arguments

keyword

Specifies which vector function ABI to use. Possible values are:

`compat`	Tells the compiler to use the compatibility vector function ABI. This ABI includes Intel®-specific features.
`cmdtarget`	Tells the compiler to generate an extended set of vector functions. The option is very similar to setting `compat`. However, for `compat`, only one vector function is created, while for `cmdtarget`, several vector functions are created for each vector specification. Vector variants are created for targets specified by compiler options `[Q]x` and/or `[Q]ax`. No change is made to the source code.
`gcc`	Tells the compiler to use the gcc vector function ABI. Use this setting only in cases when you want to link with modules compiled by gcc. This setting is not available on Windows* systems.
`legacy`	Tells the compiler to use the legacy vector function ABI. Use this setting if you need to keep the generated vector function binary backward compatible with the vectorized binary generated by older versions of the Intel® compilers (V13.1 or older).

Default

compat	The compiler uses the compatibility vector function ABI.

Description

This option determines which vector function application binary interface (ABI) the compiler uses to create or call vector functions.

> **NOTE**
> To avoid possible link-time and run-time errors, use identical `[Q]vecabi` settings when compiling all files in an application that define or use vector functions, including libraries. If setting `cmdtarget` is specified, options `[Q]x` and/or `[Q]ax` must have identical values.
>
> Be careful using setting `cmdtarget` with libraries or program modules/routines with vector function definitions that cannot be recompiled. In such cases, setting `cmdtarget` may cause link errors.

On Linux* systems, since the default is `compat`, you must specify `legacy` if you need to keep the generated vector function binary backward compatible with the vectorized binary generated by the previous version of Intel® compilers.

When `cmdtarget` is specified, the additional vector function versions are created by copying each vector specification and changing target processor in the copy. The number of vector functions is determined by the settings specified in options `[Q]x` and/or `[Q]ax`.

For example, suppose we have the following function declaration:

```
interface
integer function foo(a)
!dir$ attributes vector:(processor(core_2_duo_sse4_1)) :: foo
    integer a
end function
end interface
```

and the following options are specified: `-axAVX,CORE-AVX2`

The following table shows the different results for the above declaration and option specifications when setting `compat` or setting `cmdtarget` is used:

compat	cmdtarget
One vector version is created for Intel® SSE4.1 (by vector function specification).	Four vector versions are created for the following targets: • Intel® SSE2 (default because no `-x` option is used) • Intel® SSE4.1 (by vector function specification) • Intel® AVX (by the first `-ax` option value) • Intel® AVX2 (by the second `-ax` option value)

For more information about the Intel®-compatible vector functions ABI, see the article titled: Vector (SIMD) Function ABI, which is located in https://software.intel.com/en-us/articles/vector-simd-function-abi/

For more information about the GCC vector functions ABI, see the item Libmvec - vector math library document in the GLIBC wiki at sourceware.org.

Optimization Notice
dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice. Notice revision #20110804

Profile Guided Optimization (PGO) Options

finstrument-functions, Qinstrument-functions

Determines whether routine entry and exit points are instrumented.

Syntax

Linux OS and macOS:

`-finstrument-functions`

`-fno-instrument-functions`

Windows OS:

`/Qinstrument-functions`

`/Qinstrument-functions-`

Arguments

None

Default

`-fno-instrument-functions` Routine entry and exit points are not instrumented.
or
`/Qinstrument-functions-`

Description

This option determines whether routine entry and exit points are instrumented. It may increase execution time.

The following profiling functions are called with the address of the current routine and the address of where the routine was called (its "call site"):

- This function is called upon routine entry:

```
void __cyg_profile_func_enter (void *this_fn,
void *call_site);
```

- This function is called upon routine exit:

```
void __cyg_profile_func_exit (void *this_fn,
void *call_site);
```

These functions can be used to gather more information, such as profiling information or timing information. Note that it is the user's responsibility to provide these profiling functions.

If you specify `-finstrument-functions` (Linux* and macOS*) or `/Qinstrument-functions` (Windows*), routine inlining is disabled. If you specify `-fno-instrument-functions` or `/Qinstrument-functions-`, inlining is not disabled.

This option is provided for compatibility with gcc.

IDE Equivalent

None

Alternate Options

None

fnsplit, Qfnsplit

Enables function splitting.

Syntax

Linux OS:

`-fnsplit[=n]`

`-no-fnsplit`

macOS:

`None`

Windows OS:

`/Qfnsplit[:n]`

`/Qfnsplit-`

Arguments

n	Is an optional positive integer indicating the threshold number. The blocks can be placed into a different code segment if they are only reachable via a conditional branch whose taken probability is less than the specified *n*. Branch taken probability is heuristically calculated by the compiler and can be observed in assembly listings. The range for *n* is 0 <= n <= 100.

Default

OFF	Function splitting is not enabled. However, function grouping is still enabled.

Description

This option enables function splitting. If you specify `[Q]fnsplit` with no *n*, you must also specify option `[Q]prof-use`, or the option will have no effect and no function splitting will occur.

If you specify *n*, function splitting is enabled and you do not need to specify option `[Q]prof-use`.

To disable function splitting when you use option `[Q]prof-use`, specify `/Qfnsplit-` (Windows*) or `-no-fnsplit` (Linux*).

NOTE
Function splitting is generally not supported when exception handling is turned on for C/C++ routines in the stack of called routines. See also `-fexceptions` (Linux*).

IDE Equivalent

None

Alternate Options

Linux: `-freorder-blocks-and-partition` (a gcc option)

Windows: None

p

Compiles and links for function profiling with gprof(1).

Syntax

Linux OS and macOS:

`-p`

Windows OS:

`None`

Arguments

None

Default

OFF Files are compiled and linked without profiling.

Description

This option compiles and links for function profiling with gprof(1).

When you specify this option, inlining is disabled. However, you can override this by specifying directive FORCEINLINE, or a compiler option such as `[Q]inline-forceinline`.

IDE Equivalent

None

Alternate Options

Linux and macOS*: `-pg`,`-qp` (this is a deprecated option)

Windows: None

prof-data-order, Qprof-data-order

Enables or disables data ordering if profiling information is enabled.

Syntax

Linux OS:

`-prof-data-order`

`-no-prof-data-order`

macOS:

`None`

Windows OS:

`/Qprof-data-order`

`/Qprof-data-order-`

Arguments

None

Default

`-no-prof-data-order` Data ordering is disabled.
or
`/Qprof-data-order-`

Description

This option enables or disables data ordering if profiling information is enabled. It controls the use of profiling information to order static program data items.

For this option to be effective, you must do the following:

- For instrumentation compilation, you must specify option `[Q]prof-gen setting globdata`.
- For feedback compilation, you must specify the `[Q]prof-use` option. You must not use multi-file optimization by specifying options such as `[Q]ipo` or `[Q]ipo-c`.

IDE Equivalent

None

Alternate Options

None

See Also

prof-gen, Qprof-gen
compiler option
prof-use, Qprof-use
compiler option
prof-func-order, Qprof-func-order
compiler option

prof-dir, Qprof-dir

Specifies a directory for profiling information output files.

Syntax

Linux OS and macOS:

`-prof-dir dir`

Windows OS:

`/Qprof-dir:dir`

Arguments

dir	Is the name of the directory. You can specify a relative pathname or an absolute pathname.

Default

OFF	Profiling output files are placed in the directory where the program is compiled.

Description

This option specifies a directory for profiling information output files (*.dyn and *.dpi). The specified directory must already exist.

You should specify this option using the same directory name for both instrumentation and feedback compilations. If you move the .dyn files, you need to specify the new path.

Option `/Qprof-dir` is equivalent to option `/Qcov-dir`. If you specify both options, the last option specified on the command line takes precedence.

IDE Equivalent

Visual Studio: **Output Files > Profile Directory**

Eclipse: None

Xcode: None

Alternate Options

None

prof-file, Qprof-file

Specifies an alternate file name for the profiling summary files.

Syntax

Linux OS and macOS:

`-prof-file filename`

Windows OS:

`/Qprof-file:filename`

Arguments

filename	Is the name of the profiling summary file.

Default

OFF	The profiling summary files have the file name pgopti.*

Description

This option specifies an alternate file name for the profiling summary files. The *filename* is used as the base name for files created by different profiling passes.

If you add this option to profmerge, the .dpi file will be named *filename*.dpi instead of pgopti.dpi.

If you specify this option with option `[Q]prof-use`, the .dpi file will be named *filename*.dpi instead of pgopti.dpi.

Option `/Qprof-file` is equivalent to option `/Qcov-file`. If you specify both options, the last option specified on the command line takes precedence.

> **NOTE**
> When you use option `[Q]prof-file`, you can only specify a file name. If you want to specify a path (relative or absolute) for *filename*, you must also use option `[Q]prof-dir`.

IDE Equivalent

None

Alternate Options

None

See Also

`prof-gen, Qprof-gen` compiler option
`prof-use, Qprof-use` compiler option
`prof-dir, Qprof-dir` compiler option

prof-func-groups

Enables or disables function grouping if profiling information is enabled.

Syntax

Linux OS:

`-prof-func-groups`

`-no-prof-func-groups`

macOS:

`None`

Windows OS:

`None`

Arguments

None

Default

`-no-prof-func-groups`	Function grouping is disabled.

Description

This option enables or disables function grouping if profiling information is enabled.

A "function grouping" is a profiling optimization in which entire routines are placed either in the cold code section or the hot code section.

If profiling information is enabled by option `-prof-use`, option `-prof-func-groups` is set and function grouping is enabled. However, if you explicitly enable `-prof-func-order`, function ordering is performed instead of function grouping.

If you want to disable function grouping when profiling information is enabled, specify `-no-prof-func-groups`.

To set the hotness threshold for function grouping, use option `-prof-hotness-threshold`.

IDE Equivalent

None

See Also

`prof-use, Qprof-use` compiler option

`prof-func-order, Qprof-func-order` compiler option

`prof-hotness-threshold, Qprof-hotness-threshold` compiler option

prof-func-order, Qprof-func-order

Enables or disables function ordering if profiling information is enabled.

Syntax

Linux OS:

`-prof-func-order`

`-no-prof-func-order`

macOS:

`None`

Windows OS:

`/Qprof-func-order`

`/Qprof-func-order-`

Arguments

None

Default

`-no-prof-func-order` Function ordering is disabled.
or
`/Qprof-func-order-`

Description

This option enables or disables function ordering if profiling information is enabled.

For this option to be effective, you must do the following:

- For instrumentation compilation, you must specify option `[Q]prof-gen setting srcpos`.

- For feedback compilation, you must specify `[Q]prof-use`. You must not use multi-file optimization by specifying options such as `[Q]ipo` or `[Q]ipo-c`.

If you enable profiling information by specifying option `[Q]prof-use`, option `[Q]prof-func-groups` is set and function grouping is enabled. However, if you explicitly enable the `[Q]prof-func-order` option, function ordering is performed instead of function grouping.

On Linux* systems, this option is only available for Linux linker 2.15.94.0.1, or later.

To set the hotness threshold for function grouping and function ordering, use option `[Q]prof-hotness-threshold`.

IDE Equivalent

None

Alternate Options

None

Example

The following example shows how to use this option on a Windows system:

```
ifort /Qprof-gen:globdata file1.f90 file2.f90 /exe:instrumented.exe
    ./instrumented.exe
ifort /Qprof-use /Qprof-func-order file1.f90 file2.f90 /exe:feedback.exe
```

The following example shows how to use this option on a Linux system:

```
ifort -prof-gen:globdata file1.f90 file2.f90 -o instrumented
    ./instrumented.exe
ifort -prof-use -prof-func-order file1.f90 file2.f90 -o feedback
```

compiler option

`prof-func-groups`
compiler option

prof-gen, Qprof-gen

Produces an instrumented object file that can be used in profile guided optimization.

Syntax

Linux OS and macOS:

`-prof-gen[=keyword[, keyword],...]`

`-no-prof-gen`

Windows OS:

`/Qprof-gen[:keyword[,keyword],...]`

`/Qprof-gen-`

Arguments

keyword

Specifies details for the instrumented file. Possible values are:

`default`	Produces an instrumented object file. This is the same as specifying the `[Q]prof-gen` option with no keyword.
`srcpos`	Produces an instrumented object file that includes extra source position information.
`globdata`	Produces an instrumented object file that includes information for global data layout.
`[no]threadsafe`	Produces an instrumented object file that includes the collection of PGO data on applications that use a high level of parallelism. If `[Q]prof-gen` is specified with no keyword, the default is `nothreadsafe`.

Default

`-no-prof-gen` or `/Qprof-gen-` Profile generation is disabled.

Description

This option produces an instrumented object file that can be used in profile guided optimization. It gets the execution count of each basic block.

You can specify more than one setting for `[Q]prof-gen`. For example, you can specify the following:

```
-prof-gen=srcpos -prof-gen=threadsafe (Linux* and macOS*)
-prof-gen=srcpos, threadsafe (this is equivalent to the above)
```

```
/Qprof-gen:srcpos /Qprof-gen:threadsafe (Windows*)
/Qprof-gen:srcpos, threadsafe (this is equivalent to the above)
```

If you specify keyword `srcpos` or `globdata`, a static profile information file (.spi) is created. These settings may increase the time needed to do a parallel build using -prof-gen, because of contention writing the .spi file.

These options are used in phase 1 of the Profile Guided Optimizer (PGO) to instruct the compiler to produce instrumented code in your object files in preparation for instrumented execution.

When the `[Q]prof-gen` option is used to produce an instrumented binary file for profile generation, some optimizations are disabled. Those optimizations are not disabled for any subsequent profile-guided compilation with option `[Q]prof-use` that makes use of the generated profiles.

IDE Equivalent

None

Alternate Options

None

See Also

`prof-use, Qprof-use`
compiler option

Profile an Application with Instrumentation

prof-gen-sampling

Tells the compiler to generate debug discriminators in debug output. This aids in developing more precise sampled profiling output.

Syntax

Linux OS:

`-prof-gen-sampling`

macOS:

`None`

Windows OS:

`None`

Arguments

None

Default

OFF	The compiler does not generate debug discriminators in the debug output.

Description

This option tells the compiler to generate debug discriminators in debug output. Debug discriminators are used to distinguish code from different basic blocks that have the same source position information. This aids in developing more precise sampled hardware profiling output.

To build an executable suitable for generating hardware profiled sampled output, compile with the following options:

```
    -prof-gen-sampling -g
```

To use the data files produced by hardware profiling, compile with option `-prof-use-sampling`.

IDE Equivalent

None

Alternate Options

None

See Also

prof-use-sampling compiler option

g compiler option

Profile an Application with Instrumentation

prof-hotness-threshold, Qprof-hotness-threshold

Lets you set the hotness threshold for function grouping and function ordering.

Syntax

Linux OS:

`-prof-hotness-threshold=n`

macOS:

`None`

Windows OS:

`/Qprof-hotness-threshold:n`

Arguments

n	Is the hotness threshold. *n* is a percentage having a value between 0 and 100 inclusive. If you specify 0, there will be no hotness threshold setting in effect for function grouping and function ordering.

Default

OFF	The compiler's default hotness threshold setting of 10 percent is in effect for function grouping and function ordering.

Description

This option lets you set the hotness threshold for function grouping and function ordering.

The "hotness threshold" is the percentage of functions in the application that should be placed in the application's hot region. The hot region is the most frequently executed part of the application. By grouping these functions together into one hot region, they have a greater probability of remaining resident in the instruction cache. This can enhance the application's performance.

For this option to take effect, you must specify option `[Q]prof-use` and one of the following:

- On Linux systems: `-prof-func-groups` or `-prof-func-order`
- On Windows systems: `/Qprof-func-order`

IDE Equivalent

None

prof-src-dir, Qprof-src-dir

Determines whether directory information of the source file under compilation is considered when looking up profile data records.

Syntax

Linux OS and macOS:

`-prof-src-dir`

`-no-prof-src-dir`

Windows OS:

`/Qprof-src-dir`

`/Qprof-src-dir-`

Arguments

None

Default

[Q]prof-src-dir	Directory information is used when looking up profile data records in the .dpi file.

Description

This option determines whether directory information of the source file under compilation is considered when looking up profile data records in the .dpi file. To use this option, you must also specify the `[Q]prof-use` option.

If the option is enabled, directory information is considered when looking up the profile data records within the .dpi file. You can specify directory information by using one of the following options:

- Linux and macOS*: `-prof-src-root` or `-prof-src-root-cwd`
- Windows: `/Qprof-src-root` or `/Qprof-src-root-cwd`

If the option is disabled, directory information is ignored and only the name of the file is used to find the profile data record.

Note that option `[Q]prof-src-dir` controls how the names of the user's source files get represented within the .dyn or .dpi files. Option `[Q]prof-dir` specifies the location of the .dyn or the .dpi files.

IDE Equivalent

None

Alternate Options

None

See Also

`prof-use, Qprof-use`
compiler option

`prof-src-root, Qprof-src-root`
compiler option

`prof-src-root-cwd, Qprof-src-root-cwd`
compiler option

prof-src-root, Qprof-src-root

Lets you use relative directory paths when looking up profile data and specifies a directory as the base.

Syntax

Linux OS and macOS:

`-prof-src-root=`*dir*

Windows OS:

`/Qprof-src-root:`*dir*

Arguments

dir	Is the base for the relative paths.

Default

OFF	The setting of relevant options determines the path used when looking up profile data records.

Description

This option lets you use relative directory paths when looking up profile data in .dpi files. It lets you specify a directory as the base. The paths are relative to a base directory specified during the `[Q]prof-gen` compilation phase.

This option is available during the following phases of compilation:

- Linux* and macOS* systems: `-prof-gen` and `-prof-use` phases
- Windows* systems: `/Qprof-gen` and `/Qprof-use` phases

When this option is specified during the `[Q]prof-gen` phase, it stores information into the .dyn or .dpi file. Then, when .dyn files are merged together or the .dpi file is loaded, only the directory information below the root directory is used for forming the lookup key.

When this option is specified during the `[Q]prof-use` phase, it specifies a root directory that replaces the root directory specified at the `[Q]prof-gen` phase for forming the lookup keys.

To be effective, this option or option `[Q]prof-src-root-cwd` must be specified during the `[Q]prof-gen` phase. In addition, if one of these options is not specified, absolute paths are used in the .dpi file.

IDE Equivalent

None

Alternate Options

None

Example

Consider the initial `[Q]prof-gen` compilation of the source file c:\user1\feature_foo\myproject\common\glob.f90 shown below:

```
Linux* and macOS*: icc -prof-gen -prof-src-root=c:\user1\feature_foo\myproject -c common\glob.c
```

```
Windows*: ifort /Qprof-gen /Qprof-src-root=c:\user1\feature_foo\myproject -c common\glob.f90
```

```
Linux* and macOS*: ifort -prof-gen -prof-src-root=c:\user1\feature_foo\myproject -c common
\glob.f90
```

For the [Q]prof-use phase, the file glob.f90 could be moved into the directory c:\user2\feature_bar \myproject\common\glob.f90 and profile information would be found from the .dpi when using the following:

```
Windows*: ifort /Qprof-use /Qprof-src-root=c:\user2\feature_bar\myproject -c common\glob.f90
```

```
Linux* and macOS*: ifort -prof-use -prof-src-root=c:\user2\feature_bar\myproject -c common
\glob.f90
```

If you do not use option [Q]prof-src-root during the [Q]prof-gen phase, by default, the [Q]prof-use compilation can only find the profile data if the file is compiled in the c:\user1\feature_foo\my_project \common directory.

compiler option

prof-src-dir, Qprof-src-dir
compiler option

prof-src-root-cwd, Qprof-src-root-cwd
compiler option

prof-src-root-cwd, Qprof-src-root-cwd

Lets you use relative directory paths when looking up profile data and specifies the current working directory as the base.

Syntax

Linux OS and macOS:

`-prof-src-root-cwd`

Windows OS:

`/Qprof-src-root-cwd`

Arguments

None

Default

OFF The setting of relevant options determines the path used when looking up profile data records.

Description

This option lets you use relative directory paths when looking up profile data in .dpi files. It specifies the current working directory as the base. To use this option, you must also specify option [Q]prof-use.

This option is available during the following phases of compilation:

- Linux* and macOS* systems: -prof-gen and -prof-use phases
- Windows* systems: /Qprof-gen and /Qprof-use phases

When this option is specified during the [Q]prof-gen phase, it stores information into the .dyn or .dpi file. Then, when .dyn files are merged together or the .dpi file is loaded, only the directory information below the root directory is used for forming the lookup key.

When this option is specified during the [Q]prof-use phase, it specifies a root directory that replaces the root directory specified at the [Q]prof-gen phase for forming the lookup keys.

To be effective, this option or option `[Q]prof-src-root` must be specified during the `[Q]prof-gen` phase. In addition, if one of these options is not specified, absolute paths are used in the .dpi file.

compiler option

prof-use, Qprof-use

Enables the use of profiling information during optimization.

Syntax

Linux OS and macOS:

`-prof-use[=keyword]`

`-no-prof-use`

Windows OS:

`/Qprof-use[:keyword]`

`/Qprof-use-`

Arguments

keyword
Specifies additional instructions. Possible values are:

`weighted`
Tells the profmerge utility to apply a weighting to the .dyn file values when creating the .dpi file to normalize the data counts when the training runs have differentexecution durations. This argument only has an effect when the compiler invokes the profmerge utility to create the .dpi file. This argument does not have an effect if the .dpi file was previously created without weighting.

`[no]merge`
Enables or disables automatic invocation of the profmerge utility. The default is `merge`. Note that you cannot specify both `weighted`

	and `nomerge`. If you try to specify both values, a warning will be displayed and `nomerge` takes precedence.
`default`	Enables the use of profiling information during optimization. The profmerge utility is invoked by default. This value is the same as specifying `[Q]prof-use` with no argument.

Default

`-no-prof-use` Profiling information is not used during optimization.

or
`/Qprof-use-`

Description

This option enables the use of profiling information (including function splitting and function grouping) during optimization. It enables option /Qfnsplit (Windows*) and -fnsplit (Linux* and macOS*) .

This option instructs the compiler to produce a profile-optimized executable and it merges available profiling output files into a pgopti.dpi file.

Note that there is no way to turn off function grouping if you enable it using this option.

To set the hotness threshold for function grouping and function ordering, use option `[Q]prof-hotness-threshold`.

Profile an Application with Instrumentation

prof-use-sampling

Lets you use data files produced by hardware profiling to produce an optimized executable.

Syntax

Linux OS:

`-prof-use-sampling=`*`list`*

macOS:

`None`

Windows OS:

`None`

Arguments

list	Is a list of one or more data files. If you specify more than one data file, they must be separated by colons.

Default

OFF	Data files produced by hardware profiling will not be used to produce an optimized executable.

Description

This option lets you use data files produced by hardware profiling to produce an optimized executable.

These data files are named and produced by using Intel® VTune™.

The executable should have been produced using the following options:

```
    -prof-gen-sampling -g
```

IDE Equivalent

None

Alternate Options

None

Profile an Application with Instrumentation

prof-value-profiling, Qprof-value-profiling

Controls which values are value profiled.

Syntax

Linux OS and macOS:

`-prof-value-profiling[=keyword]`

Windows OS:

`/Qprof-value-profiling[:keyword]`

Arguments

keyword	Controls which type of value profiling is performed. Possible values are:	
	`none`	Prevents all types of value profiling.
	`nodivide`	Prevents value profiling of non-compile time constants used in division or remainder operations.
	`noindcall`	Prevents value profiling of function addresses at indirect call sites.
	`all`	Enables all types of value profiling.

You can specify more than one keyword, but they must be separated by commas.

Default

`all` All value profile types are enabled and value profiling is performed.

Description

This option controls which features are value profiled.

If this option is specified with option `[Q]prof-gen`, it turns off instrumentation of operations of the specified type. This also prevents feedback of values for the operations.

If this option is specified with option `[Q]prof-use`, it turns off feedback of values collected of the specified type.

If you specify level 2 or higher for option `[q or Q]opt-report`, the value profiling specialization information will be reported within the PGO optimization report.

IDE Equivalent

None

Alternate Options

None

Qcov-dir

Specifies a directory for profiling information output files that can be used with the codecov or tselect tool.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/Qcov-dir:`*`dir`*

Arguments

dir Is the name of the directory.

Default

OFF Profiling output files are placed in the directory where the program is compiled.

Description

This option specifies a directory for profiling information output files (*.dyn and *.dpi) that can be used with the code-coverage tool (codecov) or the test prioritization tool (tselect). The specified directory must already exist.

You should specify this option using the same directory name for both instrumentation and feedback compilations. If you move the .dyn files, you need to specify the new path.

Option `/Qcov-dir` is equivalent to option `/Qprof-dir`. If you specify both options, the last option specified on the command line takes precedence.

IDE Equivalent

None

Alternate Options

compiler option

Qcov-file

Specifies an alternate file name for the profiling summary files that can be used with the codecov or tselect tool.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/Qcov-file:`*`filename`*

Arguments

filename	Is the name of the profiling summary file.

Default

OFF	The profiling summary files have the file name pgopti.*.

Description

This option specifies an alternate file name for the profiling summary files. The file name can be used with the code-coverage tool (codecov) or the test prioritization tool (tselect).

The *filename* is used as the base name for the set of files created by different profiling passes.

If you specify this option with option `/Qcov-gen`, the .spi and .spl files will be named *filename*.spi and *filename*.spl instead of pgopti.spi and pgopti.spl.

Option `/Qcov-file` is equivalent to option `/Qprof-file`. If you specify both options, the last option specified on the command line takes precedence.

IDE Equivalent

Arguments

None

Default

`/Qcov-gen` The instrumented object file is not produced.

Description

This option produces an instrumented object file that can be used with the code-coverage tool (codecov) or the test prioritization tool (tselect). The instrumented code is included in the object file in preparation for instrumented execution.

This option also creates a static profile information file (.spi) that can be used with the codecov or tselect tool.

Option `/Qcov-gen` should be used to minimize the instrumentation overhead if you are interested in using the instrumentation only for code coverage. You should use `/Qprof-gen:srcpos` if you intend to use the collected data for code coverage and profile feedback.

IDE Equivalent

None

Alternate Options

Optimization Report Options

qopt-report, Qopt-report

Tells the compiler to generate an optimization report.

Syntax

Linux OS and macOS:

`-qopt-report[=n]`

Windows OS:

`/Qopt-report[:n]`

Arguments

n	(Optional) Indicates the level of detail in the report. You can specify values 0 through 5. If you specify zero, no report is generated. For levels *n*=1 through *n*=5, each level includes all the information of the previous level, as well as potentially some additional information. Level 5 produces the greatest level of detail. If you do not specify *n*, the default is level 2, which produces a medium level of detail.

Default

OFF	No optimization report is generated.

Description

This option tells the compiler to generate a collection of optimization report files, one per object; this is the same output produced by option `[q or Q]opt-report-per-object`.

If you prefer another form of output, you can specify option `[q or Q]opt-report-file`.

If you specify a level (*n*) higher than 5, a warning will be displayed and you will get a level 5 report.

When optimization reporting is enabled, the default is `-qopt-report-phase=all` (Linux* and macOS*) or `/Qopt-report-phase:all` (Windows*).

For a description of the information that each *n* level provides, see the Example section in option `[q or Q]opt-report-phase`.

IDE Equivalent

Visual Studio: **Diagnostics > Optimization Diagnostic Level**

Eclipse: None

Xcode: **Diagnostics > Optimization Diagnostic Level**

Alternate Options

None

Example

If you only want reports about certain diagnostics, you can use this option with option `[q or Q]opt-report-phase`. The phase you specify determines which diagnostics you will receive.

For example, the following examples show how to get reports about certain specific diagnostics.

To get this specific report	Specify

Auto-parallelizer diagnostics	Linux* and macOS*:
	`-qopt-report -qopt-report-phase=par`
	Windows*:
	`/Qopt-report /Qopt-report-phase:par`

OpenMP parallelizer diagnostics	Linux* and macOS*:
	`-qopt-report -qopt-report-phase=openmp`
	Windows*:
	`/Qopt-report /Qopt-report-phase:openmp`

Vectorizer diagnostics	Linux* and macOS*:
	`-qopt-report -qopt-report-phase=vec`
	Windows*:
	`/Qopt-report /Qopt-report-phase:vec`

See Also

`qopt-report-phase, Qopt-report-phase` compiler option

qopt-report-annotate, Qopt-report-annotate

Enables the annotated source listing feature and specifies its format.

Syntax

Linux OS and macOS:

`-qopt-report-annotate[=keyword]`

Windows OS:

`/Qopt-report-annotate[:keyword]`

Arguments

keyword Specifies the format for the annotated source listing. You can specify one of the following:

`text` Indicates that the listing should be in text format. This is the default if you do not specify *keyword*.

`html` Indicates that the listing should be in html format.

Default

OFF No annotated source listing is generated

Description

This option enables the annotated source listing feature and specifies its format. The feature annotates source files with compiler optimization reports.

By default, one annotated source file is output per object. The annotated file is written to the same directory where the object files are generated. If the object file is a temporary file and an executable is generated, annotated files are placed in the directory where the executable is placed. You cannot generate annotated files to a directory of your choosing.

However, you can output annotated listings to stdout, stderr, or to a file if you also specify option `[q or Q]opt-report-file`.

By default, this option sets option `[q or Q]opt-report` with default level 2.

The following shows the file extension and listing details for the two possible *keyword*s.

Format	Listing Details
`text`	The annotated source listing has an .annot extension. It includes line numbers and compiler diagnostics placed after correspondent lines. IPO footnotes are inserted at the end of annotated file.
`html`	The annotated source listing has an .annot.html extension. It includes line numbers and compiler diagnostics placed after correspondent lines (as the text format does). It also provides hyperlinks in compiler messages and quick navigation with the routine list. IPO footnotes are displayed as tooltips.

IDE Equivalent

None

Alternate Options

None

See Also

`qopt-report-file, Qopt-report-file` compiler option

`qopt-report-annotate-position, Qopt-report-annotate-position` compiler option

qopt-report-annotate-position, Qopt-report-annotate-position

Enables the annotated source listing feature and specifies the site where optimization messages appear in the annotated source in inlined cases of loop optimizations.

Syntax

Linux OS and macOS:

`-qopt-report-annotate-position=`*`keyword`*

Windows OS:

`/Qopt-report-annotate-position:`*`keyword`*

Arguments

`keyword` Specifies the site where optimization messages appear in the annotated source. You can specify one of the following:

`caller` Indicates that the messages should appear in the caller site.

`callee` Indicates that the messages should appear in the callee site.

`both` Indicates that the messages should appear in both the caller and the callee sites.

Default

OFF No annotated source listing is generated

Description

This option enables the annotated source listing feature and specifies the site where optimization messages appear in the annotated source in inlined cases of loop optimizations.

This option enables option `[q or Q]opt-report-annotate` if it is not explicitly specified.

If annotated source listing is enabled and this option is not passed to compiler, loop optimizations are placed in caller position by default.

IDE Equivalent

None

Alternate Options

None

`qopt-report-annotate, Qopt-report-annotate` compiler option

qopt-report-embed, Qopt-report-embed

Determines whether special loop information annotations will be embedded in the object file and/or the assembly file when it is generated.

Syntax

Linux OS and macOS:

`-qopt-report-embed`

`-qno-opt-report-embed`

Windows OS:

`/Qopt-report-embed`

`/Qopt-report-embed-`

Arguments

None

Default

OFF When an assembly file is being generated, special loop information annotations will not be embedded in the assembly file.

However, if option `-g` (Linux* and macOS*) or `/Zi` (Windows*) is specified, special loop information annotations will be embedded in the assembly file unless option `-qno-opt-report-embed` (Linux and macOS*) or `/Qopt-report-embed-` (Windows) is specified.

Description

This option determines whether special loop information annotations will be embedded in the object file and/or the assembly file when it is generated. Specify the positive form of the option to include the annotations in the assembly file.

If an object file (or executable) is being generated, the annotations will be embedded in the object file (or executable).

If you use this option, you do not have to specify option `[q or Q]opt-report`.

Alternate Options

None

See Also

`qopt-report, Qopt-report` compiler option

qopt-report-file, Qopt-report-file

Specifies that the output for the optimization report goes to a file, stderr, or stdout.

Syntax

Linux OS and macOS:

`-qopt-report-file=`*`keyword`*

Windows OS:

`/Qopt-report-file:`*`keyword`*

Arguments

`keyword` Specifies the output for the report. You can specify one of the following:

`filename`	Specifies the name of the file where the output should go.
`stderr`	Indicates that the output should go to stderr.
`stdout`	Indicates that the output should go to stdout.

Default

OFF No optimization report is generated.

Description

This option specifies that the output for the optimization report goes to a file, stderr, or stdout.

If you use this option, you do not have to specify option `[q or Q]opt-report`.

When optimization reporting is enabled, the default is `-qopt-report-phase=all` (Linux* and macOS*) or `/Qopt-report-phase:all` (Windows*).

IDE Equivalent

Visual Studio: **Diagnostics > Emit Optimization Diagnostics to File**

Diagnostics > Optimization Diagnostic File

Eclipse: None

Xcode: None

Alternate Options

None

See Also

`qopt-report, Qopt-report` compiler option

qopt-report-filter, Qopt-report-filter

Tells the compiler to find the indicated parts of your application, and generate optimization reports for those parts of your application.

Syntax

Linux OS and macOS:

`-qopt-report-filter=`*`string`*

Windows OS:

`/Qopt-report-filter:`*`string`*

Arguments

string

Is the information to search for. The *string* must appear within quotes. It can take one or more of the following forms:

filename
filename, *routine*
filename, *range* [, *range*]...
filename, *routine*, *range* [, *range*]...

If you specify more than one of the above forms in a string, a semicolon must appear between each form. If you specify more than one *range* in a string, a comma must appear between each *range*. Optional blanks can follow each parameter in the forms above and they can also follow each form in a string.

filename

Specifies the name of a file to be found. It can include a path.

If you do not specify a path, the compiler looks for the filename in the current working directory.

routine

Specifies the name of a routine to be found. You can include an identifying argument.

The name, including any argument, must be enclosed in single quotes.

The compiler tries to uniquely identify the routine that corresponds to the specified routine name.

	It may select multiple routines to analyze, especially if more than one routine has the specified routine name, so the routine cannot be uniquely identified.
range	Specifies a range of line numbers to be found in the file or routine specified. The *range* must be specified in integers in the form: *first_line_number-last_line_number* The hyphen between the line numbers is required.

Default

OFF	No optimization report is generated.

Description

This option tells the compiler to find the indicated parts of your application, and generate optimization reports for those parts of your application. Optimization reports will only be generated for the routines that contain the specified *string*.

On Linux* and macOS*, if you specify both `-qopt-report-routine=string1` and `-qopt-report-filter=string2`, it is treated as `-qopt-report-filter=string1;string2`. On Windows*, if you specify both `/Qopt-report-routine:string1` and `/Qopt-report-filter:string2`, it is treated as`/Qopt-report-filter:string1;string2`.

If you use this option, you do not have to specify option `[q or Q]opt-report`.

When optimization reporting is enabled, the default is `-qopt-report-phase=all` (Linux* and macOS*) or `/Qopt-report-phase:all` (Windows*).

IDE Equivalent

None

Alternate Options

None

See Also

`qopt-report, Qopt-report` compiler option

qopt-report-format, Qopt-report-format

Specifies the format for an optimization report.

Syntax

Linux OS and macOS:

`-qopt-report-format=`*`keyword`*

Windows OS:

`/Qopt-report-format:`*`keyword`*

Arguments

keyword Specifies the format for the report. You can specify one of the following:

`text` Indicates that the report should be in text format.

`vs` Indicates that the report should be in Visual Studio* (IDE) format. The Visual Studio IDE uses the information to visualize the optimization report in the context of your program source code.

Default

OFF No optimization report is generated.

Description

This option specifies the format for an optimization report. If you use this option, you must specify either `text` or `vs`.

If you do not specify this option and another option causes an optimization report to be generated, the default format is `text`.

If the `[q or Q]opt-report-file` option is also specified, it will affect where the output goes:

- If `filename` is specified, output goes to the specified file.
- If `stdout` is specified, output goes to stdout.
- If `stderr` is specified, output goes to stderr.

If you use this option, you do not have to specify option `[q or Q]opt-report`.

When optimization reporting is enabled, the default is `-qopt-report-phase=all` (Linux* and macOS*) or `/Qopt-report-phase:all` (Windows*).

IDE Equivalent

None

Alternate Options

None

qopt-report-help, Qopt-report-help

Displays the optimizer phases available for report generation and a short description of what is reported at each level.

Syntax

Linux OS and macOS:

```
-qopt-report-help
```

Windows OS:

```
/Qopt-report-help
```

Arguments

None

Default

OFF No optimization report is generated.

Description

This option displays the optimizer phases available for report generation using `[q or Q]opt-report-phase`, and a short description of what is reported at each level. No compilation is performed.

To indicate where output should go, you can specify one of the following options:

- `[q or Q]opt-report-file`
- `[q or Q]opt-report-per-object`

If you use this option, you do not have to specify option `[q or Q]opt-report`.

IDE Equivalent

None

Alternate Options

None

See Also

`qopt-report, Qopt-report` compiler option
`qopt-report-phase, Qopt-report-phase` compiler option
`qopt-report-file, Qopt-report-file` compiler option
`qopt-report-per-object, Qopt-report-per-object` compiler option

qopt-report-per-object, Qopt-report-per-object

Tells the compiler that optimization report information should be generated in a separate file for each object.

Syntax

Linux OS and macOS:

```
-qopt-report-per-object
```

Windows OS:

```
/Qopt-report-per-object
```

Arguments

None

Default

OFF No optimization report is generated.

Description

This option tells the compiler that optimization report information should be generated in a separate file for each object.

If you specify this option for a single-file compilation, a file with a .optrpt extension is produced for every object file or assembly file that is generated by the compiler. For a multifile Interprocedural Optimization (IPO) compilation, one file is produced for each of the N true objects generated in the compilation. If only one true object file is generated, the optimization report file generated is called ipo_out.optrpt. If multiple true object files are generated (N>1), the names used are ipo_out1.optprt, ipo_out2.optrpt, … ipo_outN.optrpt.

The .optrpt files are written to the target directory of the compilation process. If an object or assembly file is explicitly generated, the corresponding .optrpt file is written to the same directory where the object file is generated. If the object file is just a temporary file and an executable is generated, the corresponding .optrpt files are placed in the directory in which the executable is placed.

If you use this option, you do not have to specify option `[q or Q]opt-report`.

When optimization reporting is enabled, the default is `-qopt-report-phase=all` (Linux* and macOS*) or `/Qopt-report-phase:all` (Windows*).

IDE Equivalent

None

Alternate Options

None

See Also

`qopt-report, Qopt-report` compiler option

qopt-report-phase, Qopt-report-phase

Specifies one or more optimizer phases for which optimization reports are generated.

Syntax

Linux OS and macOS:

`-qopt-report-phase[=`*list*`]`

Windows OS:

`/Qopt-report-phase[:`*list*`]`

Arguments

list

(Optional) Specifies one or more phases to generate reports for. If you specify more than one phase, they must be separated with commas. The values you can specify are:

`cg`	The phase for code generation
`ipo`	The phase for Interprocedural Optimization
`loop`	The phase for loop nest optimization
`openmp`	The phase for OpenMP
`par`	The phase for auto-parallelization
`pgo`	The phase for Profile Guided Optimization
`tcollect`	The phase for trace collection

`vec`	The phase for vectorization
`all`	All optimizer phases. This is the default if you do not specify *list*.

Default

OFF No optimization report is generated.

Description

This option specifies one or more optimizer phases for which optimization reports are generated.

For certain phases, you also need to specify other options:

- If you specify phase `cg`, you must also specify option `O1`, `O2` (default), or `O3`.
- If you specify phase `ipo`, you must also specify option `[Q]ipo`.
- If you specify phase `loop`, you must also specify option `O2` (default) or `O3`.
- If you specify phase `openmp`, you must also specify option `[q or Q]openmp`.
- If you specify phase `par`, you must also specify option `[Q]parallel`.
- If you specify phase `pgo`, you must also specify option `[Q]prof-use`.
- If you specify phase `tcollect`, you must also specify option `[Q]tcollect`.
- If you specify phase `vec`, you must also specify option `O2` (default) or `O3`. If you are interested in explicit vectorization by OpenMP* SIMD, you must also specify option `[q or Q]openmp`.

To find all phase possibilities, specify option `[q or Q]opt-report-help`.

If you use this option, you do not have to specify option `[q or Q]opt-report`.

However, if you want to get more details for each phase, specify option `[q or Q]opt-report=`*n* along with this option and indicate the level of detail you want by specifying an appropriate value for *n*. (See also the Example section below.)

When optimization reporting is enabled, the default is `-qopt-report-phase=all` (Linux* and macOS*) or `/Qopt-report-phase:all` (Windows*).

IDE Equivalent

Visual Studio: **Diagnostics > Optimization Diagnostic Phase**

Eclipse: None

Xcode: **Diagnostics > Optimization Diagnostic Phase**

Alternate Options

None

Example

The following shows examples of the details you may receive when you specify one of the optimizer phases and a particular level (*n*) for option `[q or Q]opt-report`. Note that details may change in future releases.

Optimizer phase	The level specified in option `[q or Q]opt-report`	Description
`cg`	1	Generates a list of which intrinsics were lowered and which memcall optimizations were performed.

Optimizer phase	The level specified in option [q or Q]opt-report	Description
ipo	1	For each compiled routine, generates a list of the routines that were inlined into the routine, called directly by the routine, and whose calls were deleted.
	2	Generates level 1 details, values for important inlining command line options, and a list of the routines that were discovered to be dead and eliminated.
	3	Generates level 2 details, whole program information, the sizes of inlined routines, and the reasons routines were not inlined.
	4	Generates level 3 details, detailed footnotes on the reasons why routines are not inlined, and what action the user can take to get them inlined.
loop	1	Reports high-level details about which optimizations have been performed on the loop nests (along with the line number). Most of the loop optimizations (like fusion, unroll, unroll & jam, collapsing, rerolling etc) only support this level of detail.
	2	Generates level 1 details, and provides more detail on the metrics and types of references (like prefetch distance, indirect prefetches etc) used in optimizations. Only a few optimizations (like prefetching, loop classification framework etc) support these extra details.
openmp	1	Reports loops, regions, sections, and tasks successfully parallelized.
	2	Generates level 1 details, and messages indicating successful handling of MASTER constructs, SINGLE constructs, CRITICAL constructs, ORDERED constructs, ATOMIC directives, and so forth.

Optimizer phase	The level specified in option [q or Q]opt-report	Description
par	1	Reports which loops were parallelized.
	2	Generates level 1 details, and reports which loops were not parallelized along with a short reason.
	3	Generates level 2 details, and prints the memory locations that are categorized as private, shared, reduction, etc..
	4	For this phase, this is the same as specifying level 3.
	5	Generates level 4 details, and dependency edges that inhibit parallelization.
pgo	1	During profile feedback, generates report status of feedback (such as, profile used, no profile available, or unable to use profile) for each routine compiled.
	2	Generates level 1 details, and reports which value profile specializations took place for indirect calls and arithmetic operations.
	3	Generates level 2 details, and reports which indirect calls had profile data, but did not meet the internal threshold limits for the percentage or execution count.
tcollect	1	Generates a list of routines and whether each was selected for trace collection.
vec	1	Reports which loops were vectorized.
	2	Generates level 1 details and reports which loops were not vectorized along with short reason.
	3	Generates level 2 details, and vectorizer loop summary information.

Optimizer phase	The level specified in option [q or Q]opt-report	Description
	4	Generates level 3 details, and greater detail about vectorized and non-vectorized loops.
	5	Generates level 4 details, and details about any proven or assumed data dependences.

qopt-report, Qopt-report compiler option

qopt-report-help, Qopt-report-help compiler option

qopt-report-routine, Qopt-report-routine

Tells the compiler to generate an optimization report for each of the routines whose names contain the specified substring.

Syntax

Linux OS and macOS:

`-qopt-report-routine=`*substring*

Windows OS:

`/Qopt-report-routine:`*substring*

Arguments

substring	Is the text (string) to look for.

Default

OFF	No optimization report is generated.

Description

This option tells the compiler to generate an optimization report for each of the routines whose names contain the specified substring.

You can also specify a sequence of substrings separated by commas. If you do this, the compiler will generate an optimization report for each of the routines whose name contains one or more of these substrings.

If you use this option, you do not have to specify option `[q or Q]opt-report`.

When optimization reporting is enabled, the default is `-qopt-report-phase=all` (Linux* and macOS*) or `/Qopt-report-phase:all` (Windows*).

IDE Equivalent

Visual Studio: **Diagnostics > Optimization Diagnostic Routine**

Eclipse: None

Xcode: None

Alternate Options

None

See Also

qopt-report, Qopt-report compiler option

qopt-report-names, Qopt-report-names

Specifies whether mangled or unmangled names should appear in the optimization report.

Syntax

Linux OS and macOS:

`-qopt-report-names=`*keyword*

Windows OS:

`/Qopt-report-names:`*keyword*

Arguments

keyword	Specifies the form for the names. You can specify one of the following:	
	`mangled`	Indicates that the optimization report should contain mangled names.
	`unmangled`	Indicates that the optimization report should contain unmangled names.

Default

OFF	No optimization report is generated.

Description

This option specifies whether mangled or unmangled names should appear in the optimization report. If you use this option, you must specify either `mangled` or `unmangled`.

If this option is not specified, unmangled names are used by default.

If you specify `mangled`, encoding (also known as decoration) is added to names in the optimization report. This is appropriate when you want to match annotations with the assembly listing.

If you specify `unmangled`, no encoding (or decoration) is added to names in the optimization report. This is appropriate when you want to match annotations with the source listing.

If you use this option, you do not have to specify option `[q or Q]opt-report`.

When optimization reporting is enabled, the default is `-qopt-report-phase=all` (Linux* and macOS*) or `/Qopt-report-phase:all` (Windows*).

IDE Equivalent

qopt-report, Qopt-report compiler option

tcollect, Qtcollect

Inserts instrumentation probes calling the Intel® Trace Collector API.

Syntax

Linux OS:

`-tcollect[lib]`

macOS:

`None`

Windows OS:

`/Qtcollect[:lib]`

Arguments

lib	Is one of the Intel® Trace Collector libraries; for example, VT, VTcs, VTmc, or VTfs. If you do not specify *lib*, the default library is VT.

Default

OFF	Instrumentation probes are not inserted into compiled applications.

Description

This option inserts instrumentation probes calling the Intel® Trace Collector API.

This trace analyzing/collecting feature requires installation of another product. For more information, see Feature Requirements.

This option provides a flexible and convenient way of instrumenting functions of a compiled application. For every function, the entry and exit points are instrumented at compile time to let the Intel® Trace Collector record functions beyond the default MPI calls. For non-MPI applications (for example, threaded or serial), you must ensure that the Intel® Trace Collector is properly initialized (VT_initialize/VT_init).

Caution
Be careful with full instrumentation because this feature can produce very large trace files.

IDE Equivalent

None

Alternate Options

None

See Also

tcollect-filter, Qtcollect-filter
compiler option

tcollect-filter, Qtcollect-filter

Lets you enable or disable the instrumentation of specified functions. You must also specify option [Q]tcollect.

Syntax

Linux OS:

`-tcollect-filter` *filename*

macOS:

None

Windows OS:

`/Qtcollect-filter:`*filename*

Arguments

filename	Is a configuration file that lists filters, one per line. Each filter consists of a regular expression string and a switch. Strings with leading or trailing white spaces must be quoted. Other strings do not have to be quoted. The switch value can be ON, on, OFF, or off.

Default

OFF	Functions are not instrumented. However, if option `-tcollect` (Linux) or `/Qtcollect` (Windows) is specified, the filter setting is ".* ON" and all functions get instrumented.

Description

This option lets you enable or disable the instrumentation of specified functions.

To get instrumentation with a specified filter (or filters), you must specify both option `[Q]tcollect` and option `[Q]tcollect-filter`.

During instrumentation, the regular expressions in the file are matched against the function names. The switch specifies whether matching functions are to be instrumented or not. Multiple filters are evaluated from top to bottom with increasing precedence.

The names of the functions to match against are formatted as follows:

- The source file name is followed by a colon-separated function name. Source file names should contain the full path, if available. For example:

```
/home/joe/src/file.f:FOO_bar
```

- Classes and function names are separated by double colons. For example:

```
/home/joe/src/file.fpp:app::foo::bar
```

You can use option `[q or Q]opt-report` to get a full list of file and function names that the compiler recognizes from the compilation unit. This list can be used as the basis for filtering in the configuration file.

This trace analyzing/collecting feature requires installation of another product. For more information, see Feature Requirements.

IDE Equivalent

None

Alternate Options

None

Consider the following filters in a configuration file:

```
'.*' OFF '.*vector.*' ON
```

The above will cause instrumentation of only those functions having the string 'vector' in their names. No other function will be instrumented. Note that reversing the order of the two lines will prevent instrumentation of all functions.

To get a list of the file or routine strings that can be matched by the regular expression filters, generate an optimization report with tcollect information. For example:

```
Windows: ifort /Qtcollect /Qopt-report /Qopt-report-phase:tcollect
```

```
Linux: ifort -tcollect -qopt-report -qopt-report-phase=tcollect
```

OpenMP* Options and Parallel Processing Options

fmpc-privatize

Enables or disables privatization of all static data for the MultiProcessor Computing environment (MPC) unified parallel runtime.

Architecture Restrictions

Only available on Intel® 64 architecture

Syntax

Linux OS:

`-fmpc-privatize`

`-fno-mpc-privatize`

macOS:

`None`

Windows OS:

`None`

Arguments

None

Default

`-fno-mpc-privatize`	The privatization of all static data for the MPC unified parallel runtime is disabled.

Description

This option enables or disables privatization of all static data for the MultiProcessor Computing environment (MPC) unified parallel runtime.

Option `-fmpc-privatize` causes calls to extended thread-local-storage (TLS) resolution, run-time routines that are not supported on standard Linux* distributions.

This option requires installation of another product. For more information, see Feature Requirements.

IDE Equivalent

None

Alternate Options

None

par-affinity, Qpar-affinity

Specifies thread affinity.

Syntax

Linux OS:

`-par-affinity=[`*modifier*`,...]`*type*`[,`*permute*`][,`*offset*`]`

macOS:

`None`

Windows OS:

`/Qpar-affinity:[`*modifier*`,...]`*type*`[,`*permute*`][,`*offset*`]`

Arguments

modifier	Is one of the following values: `granularity={fine|thread|core|tile}`, `[no]respect`, `[no]verbose`, `[no]warnings`, `proclist=proc_list`. The default is `granularity=core, respect, and noverbose`. For information on value `proclist`, see Thread Affinity Interface.
type	Indicates the thread affinity. This argument is required and must be one of the following values: `compact`, `disabled`, `explicit`, `none`, `scatter`, `logical`, `physical`. The default is `none`. Values `logical` and `physical` are deprecated. Use `compact` and `scatter`, respectively, with no *permute* value.
permute	Is a positive integer. You cannot use this argument with *type* setting `explicit`, `none`, or `disabled`. The default is 0.
offset	Is a positive integer. You cannot use this argument with *type* setting `explicit`, `none`, or `disabled`. The default is 0.

Default

OFF	The thread affinity is determined by the run-time environment.

Description

This option specifies thread affinity, which binds threads to physical processing units. It has the same effect as environment variable KMP_AFFINITY.

This option overrides the environment variable when both are specified.

This option only has an effect if the following is true:

- You have specified option `[Q]parallel` or option `[q or Q]openmp` (or both).
- You are compiling the main program.

NOTE
This option may behave differently on Intel® microprocessors than on non-Intel microprocessors.

IDE Equivalent

None

Alternate Options

None

See Also

`parallel, Qparallel` compiler option
`qopt-report, Qopt-report` compiler option

par-num-threads, Qpar-num-threads

Specifies the number of threads to use in a parallel region.

Syntax

Linux OS and macOS:

`-par-num-threads=`*n*

Windows OS:

`/Qpar-num-threads:`*n*

Arguments

n	Is the number of threads to use. It must be a positive integer.

Default

OFF	The number of threads to use is determined by the run-time environment.

Description

This option specifies the number of threads to use in a parallel region. It has the same effect as environment variable OMP_NUM_THREADS.

This option overrides the environment variable when both are specified.

This option only has an effect if the following is true:

- You have specified option `[Q]parallel` or option `[q or Q]openmp` (or both).
- You are compiling the main program.

IDE Equivalent

None

Alternate Options

None

`parallel, Qparallel` compiler option

`qopt-report, Qopt-report` compiler option

par-runtime-control, Qpar-runtime-control

Generates code to perform run-time checks for loops that have symbolic loop bounds.

Syntax

Linux OS and macOS:

`-par-runtime-control[n]`

`-no-par-runtime-control`

Windows OS:

`/Qpar-runtime-control[n]`

`/Qpar-runtime-control-`

Arguments

n

Is a value denoting what kind of runtime checking to perform. Possible values are:

`0`	Performs no runtime check based on auto-parallelization. This is the same as specifying `-no-par-runtime-control` (Linux* and macOS*) or `/Qpar-runtime-control-` (Windows*).
`1`	Generates runtime check code under conservative mode. This is the default if you do not specify *n*.
`2`	Generates runtime check code under heuristic mode.
`3`	Generates runtime check code under aggressive mode.

Default

`-no-par-runtime-control` or `/Qpar-runtime-control-`	The compiler uses default heuristics when checking loops.

Description

This option generates code to perform run-time checks for loops that have symbolic loop bounds.

If the granularity of a loop is greater than the parallelization threshold, the loop will be executed in parallel.

If you do not specify this option, the compiler may not parallelize loops with symbolic loop bounds if the compile-time granularity estimation of a loop can not ensure it is beneficial to parallelize the loop.

NOTE
This option may behave differently on Intel® microprocessors than on non-Intel microprocessors.

IDE Equivalent

None

Alternate Options

None

par-schedule, Qpar-schedule

Lets you specify a scheduling algorithm for loop iterations.

Syntax

Linux OS and macOS:

`-par-schedule-`*keyword*`[=`*n*`]`

Windows OS:

`/Qpar-schedule-`*keyword*`[[:]`*n*`]`

Arguments

keyword

Specifies the scheduling algorithm or tuning method. Possible values are:

`auto`	Lets the compiler or run-time system determine the scheduling algorithm.
`static`	Divides iterations into contiguous pieces.
`static-balanced`	Divides iterations into even-sized chunks.
`static-steal`	Divides iterations into even-sized chunks, but allows threads to steal parts of chunks from neighboring threads.
`dynamic`	Gets a set of iterations dynamically.
`guided`	Specifies a minimum number of iterations.
`guided-analytical`	Divides iterations by using exponential distribution or dynamic distribution.
`runtime`	Defers the scheduling decision until run time.

n

Is the size of the chunk or the number of iterations for each chunk. This setting can only be specified for static, dynamic, and guided. For more information, see the descriptions of each keyword below.

Default

static-balanced

Iterations are divided into even-sized chunks and the chunks are assigned to the threads in the team in a round-robin fashion in the order of the thread number.

Description

This option lets you specify a scheduling algorithm for loop iterations. It specifies how iterations are to be divided among the threads of the team.

This option is only useful when specified with option `[Q]parallel`.

This option affects performance tuning and can provide better performance during auto-parallelization. It does nothing if it is used with option `[q or Q]openmp`.

Option	Description
`[Q]par-schedule-auto`	Lets the compiler or run-time system determine the scheduling algorithm. Any possible mapping may occur for iterations to threads in the team.
`[Q]par-schedule-static`	Divides iterations into contiguous pieces (chunks) of size *n*. The chunks are assigned to threads in the team in a round-robin fashion in the order of the thread number. Note that the last chunk to be assigned may have a smaller number of iterations. If no *n* is specified, the iteration space is divided into chunks that are approximately equal in size, and each thread is assigned at most one chunk.
`[Q]par-schedule-static-balanced`	Divides iterations into even-sized chunks. The chunks are assigned to the threads in the team in a round-robin fashion in the order of the thread number.
`[Q]par-schedule-static-steal`	Divides iterations into even-sized chunks, but when a thread completes its chunk, it can steal parts of chunks assigned to neighboring threads. Each thread keeps track of L and U, which represent the lower and upper bounds of its chunks respectively. Iterations are executed starting from the lower bound, and simultaneously, L is updated to represent the new lower bound.
`[Q]par-schedule-dynamic`	Can be used to get a set of iterations dynamically. Assigns iterations to threads in chunks as the threads request them. The thread executes the chunk of iterations, then requests another chunk, until no chunks remain to be assigned. As each thread finishes a piece of the iteration space, it dynamically gets the next set of iterations. Each chunk contains *n* iterations, except for the last chunk to be assigned, which may have fewer iterations. If no *n* is specified, the default is 1.
`[Q]par-schedule-guided`	Can be used to specify a minimum number of iterations. Assigns iterations to threads in chunks as the threads request them. The thread executes the chunk of iterations, then requests another chunk, until no chunks remain to be assigned. For a chunk of size 1, the size of each chunk is proportional to the number of unassigned iterations divided by the number of threads, decreasing to 1.

Option	Description
	For an *n* with value *k* (greater than 1), the size of each chunk is determined in the same way with the restriction that the chunks do not contain fewer than *k* iterations (except for the last chunk to be assigned, which may have fewer than *k* iterations). If no *n* is specified, the default is 1.
`[Q]par-schedule-guided-analytical`	Divides iterations by using exponential distribution or dynamic distribution. The method depends on run-time implementation. Loop bounds are calculated with faster synchronization and chunks are dynamically dispatched at run time by threads in the team.
`[Q]par-schedule-runtime`	Defers the scheduling decision until run time. The scheduling algorithm and chunk size are then taken from the setting of environment variable OMP_SCHEDULE.

NOTE
This option may behave differently on Intel® microprocessors than on non-Intel microprocessors.

IDE Equivalent

None

Alternate Options

None

par-threshold, Qpar-threshold

Sets a threshold for the auto-parallelization of loops.

Syntax

Linux OS and macOS:

`-par-threshold[n]`

Windows OS:

`/Qpar-threshold[[:]n]`

Arguments

n

Is an integer whose value is the threshold for the auto-parallelization of loops. Possible values are 0 through 100.

If *n* is 0, loops get auto-parallelized always, regardless of computation work volume.

If *n* is 100, loops get auto-parallelized when performance gains are predicted based on the compiler analysis data. Loops get auto-parallelized only if profitable parallel execution is almost certain.

The intermediate 1 to 99 values represent the percentage probability for profitable speed-up. For example, *n*=50 directs the compiler to parallelize only if there is a 50% probability of the code speeding up if executed in parallel.

Default

`-par-threshold100` or `/Qpar-threshold100`	Loops get auto-parallelized only if profitable parallel execution is almost certain. This is also the default if you do not specify *n*.

Description

This option sets a threshold for the auto-parallelization of loops based on the probability of profitable execution of the loop in parallel. To use this option, you must also specify option `[Q]parallel`.

This option is useful for loops whose computation work volume cannot be determined at compile-time. The threshold is usually relevant when the loop trip count is unknown at compile-time.

The compiler applies a heuristic that tries to balance the overhead of creating multiple threads versus the amount of work available to be shared amongst the threads.

NOTE
This option may behave differently on Intel® microprocessors than on non-Intel microprocessors.

IDE Equivalent

Visual Studio: **Optimization > Threshold For Auto-Parallelization**

Eclipse: None

Xcode: **Optimization > Threshold For Auto-Parallelization**

Alternate Options

None

parallel, Qparallel

Tells the auto-parallelizer to generate multithreaded code for loops that can be safely executed in parallel.

Syntax

Linux OS and macOS:

`-parallel`

Windows OS:

`/Qparallel(or /Qpar)`

Arguments

None

Default

OFF	Multithreaded code is not generated for loops that can be safely executed in parallel.

Description

This option tells the auto-parallelizer to generate multithreaded code for loops that can be safely executed in parallel.

To use this option, you must also specify option `O2` or `O3`.

This option sets option `[q or Q]opt-matmul` if option `O3` is also specified.

NOTE
On macOS* systems, when you enable automatic parallelization, you must also set the DYLD_LIBRARY_PATH environment variable within Xcode* or an error will be displayed.

NOTE
Using this option enables parallelization for both Intel® microprocessors and non-Intel microprocessors. The resulting executable may get additional performance gain on Intel microprocessors than on non-Intel microprocessors. The parallelization can also be affected by certain options, such as `/arch` or `/Qx` (Windows*) or `-m` or `-x` (Linux* and macOS*).

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

parallel-source-info, Qparallel-source-info

Enables or disables source location emission when OpenMP or auto-parallelism code is generated.*

Syntax

Linux OS and macOS:

`-parallel-source-info[=n]`

`-no-parallel-source-info`

Windows OS:

`/Qparallel-source-info`

`/Qparallel-source-info-[:n]`

Arguments

n

Is the level of source location emission. Possible values are:

`0`	Disables the emission of source location information when OpenMP* code or auto-parallelism code is generated. This is the same as specifying `-no-parallel-source-info` (Linux* and macOS*) or `/Qparallel-source-info-` (Windows*).
`1`	Tells the compiler to emit routine name and line information. This is the same as specifying `[Q]parallel-source-info` with no *n*.
`2`	Tells the compiler to emit path, file, routine name, and line information.

Default

`-parallel-source-info=1` or `/Qparallel-source-info:1`	When OpenMP* code or auto-parallelism code is generated, the routine name and line information is emitted.

Description

This option enables or disables source location emission when OpenMP code or auto-parallelism code is generated. It also lets you set the level of emission.

IDE Equivalent

None

Alternate Options

None

qopenmp, Qopenmp

Enables the parallelizer to generate multi-threaded code based on OpenMP directives.*

Syntax

Linux OS and macOS:

`-qopenmp`

`-qno-openmp`

Windows OS:

`/Qopenmp`

`/Qopenmp-`

Arguments

None

Default

`-qno-openmp` No OpenMP* multi-threaded code is generated by the compiler.

or
`/Qopenmp-`

Description

This option enables the parallelizer to generate multi-threaded code based on OpenMP* directives. The code can be executed in parallel on both uniprocessor and multiprocessor systems.

If you use this option, multithreaded libraries are used, but option `fpp` is not automatically invoked.

This option sets option `automatic`.

This option works with any optimization level. Specifying no optimization (`-O0` on Linux* or `/Od` on Windows*) helps to debug OpenMP applications.

To ensure that a threadsafe and/or reentrant run-time library is linked and correctly initialized, option `[q or Q]openmp` should also be used for the link step and for the compilation of the main routine.

NOTE
On macOS* systems, when you enable OpenMP* API, you must also set the DYLD_LIBRARY_PATH environment variable within Xcode* or an error will be displayed.

NOTE
Options that use OpenMP* API are available for both Intel® microprocessors and non-Intel microprocessors, but these options may perform additional optimizations on Intel® microprocessors than they perform on non-Intel microprocessors. The list of major, user-visible OpenMP constructs and features that may perform differently on Intel® microprocessors versus non-Intel microprocessors include: locks (internal and user visible), the SINGLE construct, barriers (explicit and implicit), parallel loop scheduling, reductions, memory allocation, thread affinity, and binding.

IDE Equivalent

Visual Studio: **Language > Process OpenMP Directives**

Eclipse: None

Xcode: **Language > Process OpenMP Directives**

Alternate Options

Linux and macOS*: `-fopenmp`

Windows: `/openmp`

See Also

`qopenmp-stubs, Qopenmp-stubs` compiler option

qopenmp-lib, Qopenmp-lib

Lets you specify an OpenMP run-time library to use for linking.*

Syntax

Linux OS:

`-qopenmp-lib=`*type*

macOS:

`-qopenmp-lib=`*type*

Windows OS:

`/Qopenmp-lib:`*type*

Arguments

type

Specifies the type of library to use; it implies compatibility levels. Currently, the only possible value is:

`compat`

Tells the compiler to use the compatibility OpenMP* run-time library (libiomp). This setting provides compatibility with object files created using Microsoft* and GNU* compilers.

Default

`-qopenmp-lib=compat` or `/Qopenmp-lib:compat`	The compiler uses the compatibility OpenMP* run-time library (libiomp).

Description

This option lets you specify an OpenMP* run-time library to use for linking.

The compatibility OpenMP run-time libraries are compatible with object files created using the Microsoft* OpenMP run-time library (vcomp) or the GNU OpenMP run-time library (libgomp).

To use the compatibility OpenMP run-time library, compile and link your application using the compat setting for option `[q or Q]openmp-lib`. To use this option, you must also specify one of the following compiler options:

- Linux* systems: `-qopenmp` or `-qopenmp-stubs`
- Windows* systems: `/Qopenmp` or `/Qopenmp-stubs`

On Windows* systems, the compatibility OpenMP* run-time library lets you combine OpenMP* object files compiled with the Microsoft* C/C++ compiler with OpenMP* object files compiled with the Intel® C, Intel® C++, or Intel® Fortran compilers. The linking phase results in a single, coherent copy of the run-time library.

On Linux* systems, the compatibility Intel OpenMP* run-time library lets you combine OpenMP* object files compiled with the GNU* gcc or gfortran compilers with similar OpenMP* object files compiled with the Intel® C, Intel® C++, or Intel® Fortran compilers. The linking phase results in a single, coherent copy of the run-time library.

You cannot link object files generated by the Intel® Fortran compiler to object files compiled by the GNU Fortran compiler, regardless of the presence or absence of the `[Q]openmp` compiler option. This is because the Fortran run-time libraries are incompatible.

NOTE
The compatibility OpenMP run-time library is not compatible with object files created using versions of the Intel compilers earlier than 10.0.

NOTE
On Windows* systems, this option is processed by the compiler, which adds directives to the compiled object file that are processed by the linker. On Linux* and macOS* systems, this option is processed by the `ifort` command that initiates linking, adding library names explicitly to the link command.

IDE Equivalent

None

Alternate Options

None

See Also

`qopenmp, Qopenmp` compiler option

`qopenmp-stubs, Qopenmp-stubs` compiler option

qopenmp-link

Controls whether the compiler links to static or dynamic OpenMP run-time libraries.*

Syntax

Linux OS:

`-qopenmp-link=`*`library`*

macOS:

`-qopenmp-link=`*`library`*

Windows OS:

`None`

Arguments

library

Specifies the OpenMP library to use. Possible values are:

`static`	Tells the compiler to link to static OpenMP run-time libraries. Note that static OpenMP libraries are deprecated.
`dynamic`	Tells the compiler to link to dynamic OpenMP run-time libraries.

Default

`-qopenmp-link=dynamic`

The compiler links to dynamic OpenMP* run-time libraries. However, if Linux* option `-static` is specified, the compiler links to static OpenMP run-time libraries.

Description

This option controls whether the compiler links to static or dynamic OpenMP* run-time libraries.

To link to the static OpenMP run-time library (RTL) and create a purely static executable, you must specify `-qopenmp-link=static`. However, we strongly recommend you use the default setting, `-qopenmp-link=dynamic`.

NOTE
Compiler options `-static-intel` and `-shared-intel` (Linux* and macOS*) have no effect on which OpenMP run-time library is linked.

NOTE
On Linux* systems, `-qopenmp-link=dynamic` cannot be used in conjunction with option `-static`. If you try to specify both options together, an error will be displayed.

NOTE
On Linux systems, the OpenMP runtime library depends on using libpthread and libc (libgcc when compiled with gcc). Libpthread and libc (libgcc) must both be static or both be dynamic. If both libpthread and libc (libgcc) are static, then the static version of the OpenMP runtime should be used. If both libpthread and libc (libgcc) are dynamic, then either the static or dynamic version of the OpenMP runtime may be used.

IDE Equivalent

None

Alternate Options

None

qopenmp-offload

Enables or disables OpenMP offloading compilation for the TARGET directives.*

Syntax

Linux OS:

`-qopenmp-offload[=device]`

`-qno-openmp-offload`

macOS:

`None`

Windows OS:

`None`

Arguments

device Specifies the default device for target pragmas. Possible values are:

`host`	OpenMP* offloading constructs are ignored. For Openmp* combined offload constructs, only the offloading part is ignored.

None

Default

`-qno-openmp-offload`	OpenMP* offloading compilation is disabled. However, if option `qopenmp` is specified, the default is ON and OpenMP offloading compilation is enabled.

Description

This option enables or disables OpenMP* offloading compilation for the TARGET directives. When enabling offloading, it lets you specify what the default target device should be for the TARGET directives. .

NOTE
The TARGET directives are only available on Linux* systems.

You can also use this option if you want to enable or disable the offloading feature with no impact on other OpenMP* features. In this case, no OpenMP runtime library is needed to link and the compiler does not need to generate OpenMP runtime initialization code.

If you specify this option with the `qopenmp` option, it can impact other OpenMP* features.

IDE Equivalent

None

Alternate Options

None

Example

Consider the following:

```
-qno-openmp -qopenmp-offload
```

The above is equivalent to specifying only `qopenmp-offload`. In this case, only the offload library is linked, not the OpenMP* library, and only the !$OMP directives for TARGET are processed but no other !$OMP directives.

Consider the following:

```
-qopenmp -qopenmp-offload
```

In this case, the offload library is linked, the OpenMP library is linked, and OpenMP runtime initialization code is generated.

See Also

`qopenmp, Qopenmp` compiler option
TARGET directive
TARGET DATA directive
TARGET UPDATE directive

qopenmp-simd, Qopenmp-simd

Enables or disables OpenMP SIMD compilation.*

Syntax

Linux OS and macOS:

`-qopenmp-simd`

`-qno-openmp-simd`

Windows OS:

`/Qopenmp-simd`

`/Qopenmp-simd-`

Arguments

None

Default

`-qopenmp-simd` or `/Qopenmp-simd`	OpenMP* SIMD compilation is enabled if option `O2` or higher is in effect.

OpenMP* SIMD compilation is always disabled at optimization levels of `O1` or lower.

When option `O2` or higher is in effect, OpenMP SIMD compilation can only be disabled by specifying option `-qno-openmp-simd` or `/Qopenmp-simd-`. It is not disabled by specifying option `-qno-openmp` or `/Qopenmp-`.

Description

This option enables or disables OpenMP* SIMD compilation.

You can use this option if you want to enable or disable the SIMD support with no impact on other OpenMP features. In this case, no OpenMP runtime library is needed to link and the compiler does not need to generate OpenMP runtime initialization code.

If you specify this option with the `[q or Q]openmp` option, it can impact other OpenMP features.

IDE Equivalent

None

Alternate Options

None

Example

Consider the following:

```
-qno-openmp -qopenmp-simd    ! Linux or macOS*
/Qopenmp- /Qopenmp-simd      ! Windows
```

The above is equivalent to specifying only `[q or Q]openmp-simd`. In this case, only SIMD support is provided, the OpenMP* library is not linked, and only the !$OMP directives related to SIMD are processed.

Consider the following:

```
-qopenmp -qopenmp-simd       ! Linux or macOS*
/Qopenmp /Qopenmp-simd       ! Windows
```

In this case, SIMD support is provided, the OpenMP library is linked, and OpenMP runtime initialization code is generated.

See Also

`qopenmp, Qopenmp` compiler option
`O` compiler option
SIMD Directive (OpenMP* API) directive

qopenmp-stubs, Qopenmp-stubs

Enables compilation of OpenMP programs in sequential mode.*

Syntax

Linux OS:

`-qopenmp-stubs`

macOS:

`-qopenmp-stubs`

Windows OS:

`/Qopenmp-stubs`

Arguments

None

Default

OFF The library of OpenMP* function stubs is not linked.

Description

This option enables compilation of OpenMP* programs in sequential mode. The OpenMP directives are ignored and a stub OpenMP library is linked.

IDE Equivalent

Visual Studio: **Language > Process OpenMP Directives**

Eclipse: None

Xcode: **Language > Process OpenMP Directives**

Alternate Options

None

See Also

`qopenmp, Qopenmp` compiler option

qopenmp-threadprivate, Qopenmp-threadprivate

Lets you specify an OpenMP threadprivate implementation.*

Syntax

Linux OS:

`-qopenmp-threadprivate=`*type*

macOS:

`None`

Windows OS:

`/Qopenmp-threadprivate:`*type*

Arguments

type	Specifies the type of threadprivate implementation. Possible values are:	
	`legacy`	Tells the compiler to use the legacy OpenMP* threadprivate implementation used in the previous releases of the Intel® compiler. This setting does not provide compatibility with the implementation used by other compilers.

	`compat`	Tells the compiler to use the compatibility OpenMP* threadprivate implementation based on applying the thread-local attribute to each threadprivate variable. This setting provides compatibility with the implementation provided by the Microsoft* and GNU* compilers.

Default

`-qopenmp-threadprivate=legacy` or `/Qopenmp-threadprivate:legacy`	The compiler uses the legacy OpenMP* threadprivate implementation used in the previous releases of the Intel compiler.

Description

This option lets you specify an OpenMP* threadprivate implementation.

The threadprivate implementation of the legacy OpenMP run-time library may not be compatible with object files created using OpenMP run-time libraries supported in other compilers.

To use this option, you must also specify one of the following compiler options:

- Linux* systems: `-qopenmp` or `-qopenmp-stubs`
- Windows* systems: `/Qopenmp` or `/Qopenmp-stubs`

The value specified for this option is independent of the value used for the `[q or Q]openmp-lib` option.

NOTE
On Windows* systems, if you specify option `/Qopenmp-threadprivate:compat`, the compiler does not generate threadsafe code for common blocks in an !$OMP THREADPRIVATE directive unless at least one element in the common block is explicitly initialized. For more information, see the article titled: /Qopenmp-threadprivate:compat doesn't work with uninitialized threadprivate common blocks, which is located in http://intel.ly/1aHhsjc

NOTE
On macOS* systems, legacy is the only type of threadprivate supported. Option `-qopenmp-threadprivate` is not recognized by the compiler.

IDE Equivalent

None

Alternate Options

None

Qpar-adjust-stack

Tells the compiler to generate code to adjust the stack size for a fiber-based main thread.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/Qpar-adjust-stack:`*n*

Arguments

n	Is the stack size (in bytes) for the fiber-based main thread. It must be a number equal to or greater than zero.

Default

`/Qpar-adjust-stack:0`	No adjustment is made to the main thread stack size.

Description

This option tells the compiler to generate code to adjust the stack size for a fiber-based main thread. This can reduce the stack size of threads.

For this option to be effective, you must also specify option `/Qparallel`.

IDE Equivalent

None

Alternate Options

None

See Also

`parallel, Qparallel` compiler option

Floating-Point Options

fast-transcendentals, Qfast-transcendentals

Enables the compiler to replace calls to transcendental functions with faster but less precise implementations.

Syntax

Linux OS and macOS:

`-fast-transcendentals`

`-no-fast-transcendentals`

Windows OS:

`/Qfast-transcendentals`

`/Qfast-transcendentals-`

Arguments

None

Default

depends on the setting of `-fp-model` (Linux* and macOS*) or `/fp` (Windows*)	If you do not specify option `-[no-]fast-transcendentals`or option /Qfast-transcendentals[-]: • The default is ON if option `-fp-model fast` or `/fp:fast` is specified or is in effect. • The default is OFF if a value-safe setting is specified for `-fp-model` or `/fp` (such as "precise", "source", etc.).

Description

This option enables the compiler to replace calls to transcendental functions with implementations that may be faster but less precise.

It allows the compiler to perform certain optimizations on transcendental functions, such as replacing individual calls to sine in a loop with a single call to a less precise vectorized sine library routine. These optimizations can cause numerical differences that would not otherwise exist if you are also compiling with a value-safe option such as `-fp-model precise` (Linux* and macOS*) or `/fp:precise` (Windows).

For example, you may get different results if you specify option `O0` versus option `O2`, or you may get different results from calling the same function with the same input at different points in your program. If these kinds of numerical differences are problematic, consider using option `-fimf-use-svml` (Linux* and macOS*) or `/Qimf-use-svml` (Windows) as an alternative. When used with a value-safe option such as `-fp-model precise` or `/fp:precise`, option `-fimf-use-svml` or `/Qimf-use-svml` provides many of the positive performance benefits of `[Q]fast-transcendentals` without negatively affecting numeric consistency. For more details, see the description of option `-fimf-use-svml` and `/Qimf-use-svml`.

This option does not affect explicit Short Vector Math Library (SVML) intrinsics. It only affects scalar calls to the standard math library routines.

You cannot use option `-fast-transcendentals` with option `-fp-model strict` and you cannot use option `/Qfast-transcendentals` with option `/fp:strict`.

This option determines the setting for the maximum allowable relative error for math library function results (max-error) if none of the following options are specified:

- `-fimf-accuracy-bits` (Linux* and macOS*) or `/Qimf-accuracy-bits` (Windows*)
- `-fimf-max-error` (Linux and macOS*) or `/Qimf-max-error` (Windows)
- `-fimf-precision` (Linux and macOS*) or `/Qimf-precision` (Windows)

This option enables extra optimization that only applies to Intel® processors.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

fimf-absolute-error, Qimf-absolute-error

Defines the maximum allowable absolute error for math library function results.

Syntax

Linux OS:

`-fimf-absolute-error=`*value*`[:`*funclist*`]`

macOS:

`-fimf-absolute-error=`*value*`[:`*funclist*`]`

Windows OS:

`/Qimf-absolute-error:`*value*`[:`*funclist*`]`

Arguments

value

Is a positive, floating-point number. Errors in math library function results may exceed the maximum relative error (max-error) setting if the absolute-error is less than or equal to *value*.

The format for the number is [digits] [.digits] [{ e | E }[sign]digits]

funclist

Is an optional list of one or more math library functions to which the attribute should be applied. Do not specify the standard Fortran name of the math function; you must specify the actual math library name. If you specify more than one function, they must be separated with commas.

Precision-specific variants like sin and sinf are considered different functions, so you would need to use `-fimf-absolute-error=0.00001:sin,sinf` (or `/Qimf-absolute-error:0.00001:sin,sinf`) to specify the maximum allowable absolute error for both the single-precision and double-precision sine functions.

You also can specify the symbol /f to denote single-precision divides, symbol / to denote double-precision divides, symbol /l to denote extended-precision divides, and symbol /q to denote quad-precision

divides. For example you can specify
`-fimf-absolute-error=0.00001:/`
or `/Qimf-absolute-error: 0.00001:/`.

Default

Zero ("0")	An absolute-error setting of 0 means that the function is bound by the relative error setting. This is the default behavior.

Description

This option defines the maximum allowable absolute error for math library function results.

This option can improve run-time performance, but it may decrease the accuracy of results.

This option only affects functions that have zero as a possible return value, such as log, sin, asin, etc.

The relative error requirements for a particular function are determined by options that set the maximum relative error (max-error) and precision. The return value from a function must have a relative error less than the max-error value, or an absolute error less than the absolute-error value.

If you need to define the accuracy for a math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sinf, as in `-fimf-absolute-error=0.00001:sin` or `/Qimf-absolute-error:0.00001:sin`, or `-fimf-absolute-error=0.00001:sqrtf` or `/Qimf-absolute-error:0.00001:sqrtf`.

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, sinf applies only to the single-precision sine function, sin applies only to the double-precision sine function, sinl applies only to the extended-precision sine function, etc.

NOTE
Many routines in libraries LIBM (Math Library) and SVML (Short Vector Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

NOTE
The standard Fortran names for the various math intrinsic functions *do not* match the math library names of the math intrinsic functions. You must find the actual math library name that is generated for the relevant Fortran math intrinsic.

One way to do this is to generate assembly code by using options `/Fa` or `/S` on Windows, or option `-S` on Linux. The assembly code will show the actual math library name.

For example, if you create a program that contains a call to SIN(x) where x is declared as REAL(KIND=4) and then use option `/S` on Windows to produce assembly code for the program, the assembly code will show a call to sinf.

Therefore, to define the maximum allowable absolute error for the single-precision sine function, you would specify `-fimf-absolute-error=sinf` (or `/Qimf-absolute-error:sinf`).

fimf-accuracy-bits, Qimf-accuracy-bits

Defines the relative error for math library function results, including division and square root.

Syntax

Linux OS:

`-fimf-accuracy-bits=`*`bits`*`[:`*`funclist`*`]`

macOS:

`-fimf-accuracy-bits=`*`bits`*`[:`*`funclist`*`]`

Windows OS:

`/Qimf-accuracy-bits:`*`bits`*`[:`*`funclist`*`]`

Arguments

bits	Is a positive, floating-point number indicating the number of correct bits the compiler should use. The format for the number is [digits] [.digits] [{ e | E }[sign]digits].
funclist	Is an optional list of one or more math library functions to which the attribute should be applied. Do not specify the standard Fortran name of the math function; you must specify the actual math library name. If you specify more than one function, they must be separated with commas.

Precision-specific variants like sin and sinf are considered different functions, so you would need to use `-fimf-accuracy-bits=23:sin,sinf` (or `/Qimf-accuracy-bits:23:sin,sinf`) to specify the relative error for both the single-precision and double-precision sine functions.

You also can specify the symbol /f to denote single-precision divides, symbol / to denote double-precision divides, symbol /l to denote extended-precision divides, and symbol /q to denote quad-precision divides. For example you can specify `-fimf-accuracy-bits=10.0:/f` or `/Qimf-accuracy-bits:10.0:/f`.

Default

-fimf-precision=medium or /Qimf-precision:medium	The compiler uses medium precision when calling math library functions. Note that other options can affect precision; see below for details.

Description

This option defines the relative error, measured by the number of correct bits, for math library function results.

The following formula is used to convert bits into ulps: ulps = $2^{p-1-bits}$, where p is the number of the target format mantissa bits (24, 53, and 113 for single, double, and quad precision, respectively).

This option can affect run-time performance and the accuracy of results.

If you need to define the accuracy for a math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sinf, as in the following:

- `-fimf-accuracy-bits=23:sinf,cosf,logf` or `/Qimf-accuracy-bits:23:sinf,cosf,logf`
- `-fimf-accuracy-bits=52:sqrt,/,trunc` or `/Qimf-accuracy-bits:52:sqrt,/,trunc`
- `-fimf-accuracy-bits=10:powf` or `/Qimf-accuracy-bits:10:powf`

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, sinf applies only to the single-precision sine function, sin applies only to the double-precision sine function, sinl applies only to the extended-precision sine function, etc.

There are three options you can use to express the maximum relative error. They are as follows:

- `-fimf-precision` (Linux* and macOS*) or `/Qimf-precision` (Windows*)
- `-fimf-max-error` (Linux* and macOS*) or `/Qimf-max-error` (Windows*)
- `-fimf-accuracy-bits` (Linux and macOS*) or `/Qimf-accuracy-bits` (Windows)

If more than one of these options are specified, the default value for the maximum relative error is determined by the last one specified on the command line.

If none of the above options are specified, the default values for the maximum relative error are determined by the setting of the following options:

- `[Q]fast-transcendentals`
- `[Q]prec-div`
- `[Q]prec-sqrt`

- `-fp-model` (Linux and macOS*) or `/fp` (Windows)

NOTE
Many routines in libraries LIBM (Math Library) and SVML (Short Vector Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

NOTE
The standard Fortran names for the various math intrinsic functions *do not* match the math library names of the math intrinsic functions. You must find the actual math library name that is generated for the relevant Fortran math intrinsic.

One way to do this is to generate assembly code by using options `/Fa` or `/S` on Windows, or option `-S` on Linux. The assembly code will show the actual math library name.

For example, if you create a program that contains a call to SIN(x) where x is declared as REAL(KIND=4) and then use option `/S` on Windows to produce assembly code for the program, the assembly code will show a call to sinf.

Therefore, to request the relative error for the single-precision sine function, you would specify `-fimf-accuracy-bits=sinf` (or `/Qimf-accuracy-bits:sinf`).

fimf-arch-consistency, Qimf-arch-consistency

Ensures that the math library functions produce consistent results across different microarchitectural implementations of the same architecture.

Syntax

Linux OS:

`-fimf-arch-consistency=`*value*`[:`*funclist*`]`

macOS:

`-fimf-arch-consistency=`*value*`[:`*funclist*`]`

Windows OS:

`/Qimf-arch-consistency:`*value*`[:`*funclist*`]`

Arguments

value	Is one of the logical values "true" or "false".
funclist	Is an optional list of one or more math library functions to which the attribute should be applied. Do not specify the standard Fortran name of the math function; you must specify the actual math library name. If you specify more than one function, they must be separated with commas. Precision-specific variants like sin and sinf are considered different functions, so you would need to use `-fimf-arch-consistency=true:sin,sinf` (or `/Qimf-arch-consistency:true:sin,sinf`) to specify consistent results for both the single-precision and double-precision sine functions. You also can specify the symbol /f to denote single-precision divides, symbol / to denote double-precision divides, symbol /l to denote extended-precision divides, and symbol /q to denote quad-precision divides. For example you can specify `-fimf-arch-consistency=true:/` or `/Qimf-arch-consistency:true:/`.

Default

false	Implementations of some math library functions may produce slightly different results on implementations of the same architecture.

Description

This option ensures that the math library functions produce consistent results across different microarchitectural implementations of the same architecture (for example, across different microarchitectural implementations of IA-32 architecture). Consistency is only guaranteed for a single binary. Consistency is not guaranteed across different architectures. For example, consistency is not guaranteed across IA-32 architecture and Intel® 64 architecture.

If you need to define the accuracy for a math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sinf, as in `-fimf-arch-consistency=true:sin` or `/Qimf-arch-consistency:true:sin`, or `-fimf-arch-consistency=false:sqrtf` or `/Qimf-arch-consistency:false:sqrtf`.

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, sinf applies only to the single-precision sine function, sin applies only to the double-precision sine function, sinl applies only to the extended-precision sine function, etc.

The `-fimf-arch-consistency` (Linux* and macOS*) and `/Qimf-arch-consistency` (Windows*) option may decrease run-time performance, but the option will provide bit-wise consistent results on all Intel® processors and compatible, non-Intel processors, regardless of micro-architecture. This option may not provide bit-wise consistent results between different architectures.

NOTE
Many routines in libraries LIBM (Math Library) and SVML (Short Vector Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

NOTE
The standard Fortran names for the various math intrinsic functions *do not* match the math library names of the math intrinsic functions. You must find the actual math library name that is generated for the relevant Fortran math intrinsic.

One way to do this is to generate assembly code by using options `/Fa` or `/S` on Windows, or option `-S` on Linux. The assembly code will show the actual math library name.

For example, if you create a program that contains a call to SIN(x) where x is declared as REAL(KIND=4) and then use option `/S` on Windows to produce assembly code for the program, the assembly code will show a call to sinf.

Therefore, to ensure consistent results for the single-precision sine function, you would specify `-fimf-arch-consistency=sinf` (or `/Qimf-arch-consistency:sinf`).

fimf-domain-exclusion, Qimf-domain-exclusion

Indicates the input arguments domain on which math functions must provide correct results.

Syntax

Linux OS:

`-fimf-domain-exclusion=`*`classlist`*`[:`*`funclist`*`]`

macOS:

`-fimf-domain-exclusion=`*`classlist`*`[:`*`funclist`*`]`

Windows OS:

`/Qimf-domain-exclusion:`*`classlist`*`[:`*`funclist`*`]`

Arguments

classlist

Is one of the following:

- One or more of the following floating-point value classes you can exclude from the function domain without affecting the correctness of your program. The supported class names are:

`extremes`	This class is for values which do not lie within the usual domain of arguments for a given function.
`nans`	This means "x=Nan".
`infinities`	This means "x=infinities".
`denormals`	This means "x=denormal".
`zeros`	This means "x=0".

Each *classlist* element corresponds to a power of two. The exclusion attribute is the logical or of the associated powers of two (that is, a bitmask).

The following shows the current mapping from *classlist* mnemonics to numerical values:

extremes	1
nans	2
infinities	4
denormals	8

zeros	16
none	0
all	31
common	15
other combinations	bitwise OR of the used values

You must specify the integer value that corresponds to the class that you want to exclude.

Note that on excluded values, unexpected results may occur.

- One of the following short-hand tokens:

`none` This means that none of the supported classes are excluded from the domain. To indicate this token, specify 0, as in `-fimf-domain-exclusion=0` (or `/Qimf-domain-exclusion:0`).

`all` This means that all of the supported classes are excluded from the domain. To indicate this token, specify 31, as in `-fimf-domain-exclusion=31` (or `/Qimf-domain-exclusion:31`).

`common` This is the same as specifying extremes,nans,infinities,subnormals. To indicate this token, specify 15 (1 + 2+ 4 + 8), as in `-fimf-domain-exclusion=15` (or `/Qimf-domain-exclusion:15`)

funclist

Is an optional list of one or more math library functions to which the attribute should be applied. Do not specify the standard Fortran name of the math function; you must specify the actual math library name. If you specify more than one function, they must be separated with commas.

Precision-specific variants like sin and sinf are considered different functions, so you would need to use `-fimf-domain-exclusion=4:sin,sinf` (or `/Qimf-domain-exclusion:4:sin,sinf`) to specify infinities for both the single-precision and double-precision sine functions.

You also can specify the symbol /f to denote single-precision divides, symbol / to denote double-precision divides, symbol /l to denote extended-precision divides, and symbol /q to denote quad-precision divides. For example, you can specify:

`-fimf-domain-exclusion=4` or `/Qimf-domain-exclusion:4`

`-fimf-domain-exclusion=5:/,powf`
or `/Qimf-domain-exclusion:5:/,powf`

`-fimf-domain-exclusion=23:log,logf,/,sin,cosf`
or `/Qimf-domain-exclusion:23:log,logf,/,sin,cosf`

If you don't specify argument *funclist*, the domain restrictions apply to all math library functions.

Default

Zero ("0") The compiler uses default heuristics when calling math library functions.

Description

This option indicates the input arguments domain on which math functions must provide correct results. It specifies that your program will function correctly if the functions specified in *funclist* do not produce standard conforming results on the number classes.

This option can affect run-time performance and the accuracy of results. As more classes are excluded, faster code sequences can be used.

If you need to define the accuracy for a math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sinf, as in `-fimf-domain-exclusion=subnormals:sin` or `/Qimf-domain-exclusion:subnormals:sin`, or `-fimf-domain-exclusion=extremes:sqrtf` or `/Qimf-domain-exclusion:extremes:sqrtf`.

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, sinf applies only to the single-precision sine function, sin applies only to the double-precision sine function, sinl applies only to the extended-precision sine function, etc.

NOTE
Many routines in libraries LIBM (Math Library) and SVML (Short Vector Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

NOTE
The standard Fortran names for the various math intrinsic functions *do not* match the math library names of the math intrinsic functions. You must find the actual math library name that is generated for the relevant Fortran math intrinsic.

One way to do this is to generate assembly code by using options `/Fa` or `/S` on Windows, or option `-S` on Linux. The assembly code will show the actual math library name.

For example, if you create a program that contains a call to SIN(x) where x is declared as REAL(KIND=4) and then use option `/S` on Windows to produce assembly code for the program, the assembly code will show a call to sinf.

Therefore, to indicate the input arguments domain for the single-precision sine function, you would specify `-fimf-domain-exclusion=sinf` (or `/Qimf-domain-exclusion:sinf`).

Optimization Notice
optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice. Notice revision #20110804

IDE Equivalent

None

Alternate Options

None

Example

Consider the following single-precision sequence for function exp2f:

Operation:	y = exp2f(x)
Accuracy:	1.014 ulp
Instructions:	4 (2 without fix-up)

The following shows the 2-instruction sequence without the fix-up:

```
vcvtfxpntps2dq  zmm1 {k1}, zmm0, 0x50      // zmm1 <-- rndToInt(2^24 * x)
vexp223ps       zmm1 {k1}, zmm1            // zmm1 <-- exp2(x)
```

However, the above 2-instruction sequence will not correctly process NaNs. To process Nans correctly, the following fix-up must be included following the above instruction sequence:

```
vpxord          zmm2, zmm2, zmm2             // zmm2 <-- 0
vfixupnanps     zmm1 {k1}, zmm0, zmm2 {aaaa} // zmm1 <-- QNaN(x) if x is NaN <F>
```

If the `vfixupnanps` instruction is not included, the sequence correctly processes any arguments except NaN values. For example, the following options generate the 2-instruction sequence:

```
-fimf-domain-exclusion=2:exp2f      <- NaN’s are excluded (2 corresponds to NaNs)
-fimf-domain-exclusion=6:exp2f      <- NaN’s and infinities are excluded (4 corresponds to
infinities; 2 + 4 = 6)
-fimf-domain-exclusion=7:exp2f      <- NaN’s, infinities, and extremes are excluded (1
corresponds to extremes; 2 + 4 + 1 = 7)
-fimf-domain-exclusion=15:exp2f     <- NaN’s, infinities, extremes, and subnormals are excluded
(8 corresponds to subnormals;  2 + 4 + 1 + 8=15)
```

If the `vfixupnanps` instruction is included, the sequence correctly processes any arguments including NaN values. For example, the following options generate the 4-instruction sequence:

```
-fimf-domain-exclusion=1:exp2f      <- only extremes are excluded (1 corresponds to extremes)
-fimf-domain-exclusion=4:exp2f      <- only infinities are excluded (4 corresponds to infinities)
-fimf-domain-exclusion=8:exp2f      <- only subnormals are excluded (8 corresponds to subnormals)
-fimf-domain-exclusion=13:exp2f     <- only extremes, infinities and subnormals are excluded (1
+ 4 + 8 = 13)
```

fimf-force-dynamic-target, Qimf-force-dynamic-target

Instructs the compiler to use run-time dispatch in calls to math functions.

Syntax

Linux OS:

`-fimf-force-dynamic-target[=`*`funclist`*`]`

macOS:

`-fimf-force-dynamic-target[=`*`funclist`*`]`

Windows OS:

`/Qimf-force-dynamic-target[:`*`funclist`*`]`

Arguments

funclist

Is an optional list of one or more math library functions to which the attribute should be applied. Do not specify the standard Fortran name of the math function; you must specify the actual math library name. If you specify more than one function, they must be separated with commas.

Precision-specific variants like sin and sinf are considered different functions, so you would need to use `-fimf-dynamic-target=sin,sinf` (or `/Qimf-dynamic-target:sin,sinf`) to specify run-time dispatch for both the single-precision and double-precision sine functions.

You also can specify the symbol /f to denote single-precision divides, symbol / to denote double-precision divides, symbol /l to denote extended-precision divides, and symbol /q to denote quad-precision divides. For example, you can specify `-fimf-dynamic-target=/` or `/Qimf-dynamic-target:/`.

Default

OFF

Run-time dispatch is not forced in math libraries calls. The compiler can choose to call a CPU-specific version of a math function if one is available.

Description

This option instructs the compiler to use run-time dispatch in calls to math functions. When this option set to ON, it lets you force run-time dispatch in math libraries calls.

By default, when this option is set to OFF, the compiler often optimizes math library calls using the target CPU architecture-specific information available at compile time through the `[Q]x` and `arch` compiler options.

If you want to target multiple CPU families with a single application or you prefer to choose a target CPU at run time, you can force run-time dispatch in math libraries by using this option.

NOTE
The standard Fortran names for the various math intrinsic functions *do not* match the math library names of the math intrinsic functions. You must find the actual math library name that is generated for the relevant Fortran math intrinsic.

One way to do this is to generate assembly code by using options `/Fa` or `/S` on Windows, or option `-S` on Linux. The assembly code will show the actual math library name.

For example, if you create a program that contains a call to SIN(x) where x is declared as REAL(KIND=4) and then use option `/S` on Windows to produce assembly code for the program, the assembly code will show a call to sinf.

Therefore, to use run-time dispatch in calls to the single-precision sine function, you would specify `-fimf-force-dynamic-target=sinf` (or `/Qimf-force-dynamic-target:sinf`).

IDE Equivalent

fimf-max-error, Qimf-max-error

Defines the maximum allowable relative error for math library function results, including division and square root.

Syntax

Linux OS:

`-fimf-max-error=`*`ulps`*`[:`*`funclist`*`]`

macOS:

`-fimf-max-error=`*`ulps`*`[:`*`funclist`*`]`

Windows OS:

`/Qimf-max-error:`*`ulps`*`[:`*`funclist`*`]`

Arguments

ulps	Is a positive, floating-point number indicating the maximum allowable relative error the compiler should use. The format for the number is [digits] [.digits] [{ e | E }[sign]digits].
funclist	Is an optional list of one or more math library functions to which the attribute should be applied. Do not specify the standard Fortran name of the math function; you must specify the actual math library name. If you specify more than one function, they must be separated with commas. Precision-specific variants like sin and sinf are considered different functions, so you would need to use `-fimf-max-error=4.0:sin,sinf` (or `/Qimf-max-error=4.0:sin,sinf`) to specify the maximum allowable relative error for both the single-precision and double-precision sine functions. You also can specify the symbol /f to denote single-precision divides, symbol / to denote double-precision divides, symbol /l to denote extended-precision divides, and symbol /q to denote quad-precision divides. For example you can specify `-fimf-max-error=4.0:/` or `/Qimf-max-error:4.0:/`.

Default

-fimf-precision=medium or /Qimf-precision:medium	The compiler uses medium precision when calling math library functions. Note that other options can affect precision; see below for details.

Description

This option defines the maximum allowable relative error, measured in ulps, for math library function results.

This option can affect run-time performance and the accuracy of results.

If you need to define the accuracy for a math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sinf, as in `-fimf-max-error=4.0:sin` or `/Qimf-max-error:4.0:sin`, or `-fimf-max-error=4.0:sqrtf` or `/Qimf-max-error:4.0:sqrtf`.

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, sinf applies only to the single-precision sine function, sin applies only to the double-precision sine function, sinl applies only to the extended-precision sine function, etc.

There are three options you can use to express the maximum relative error. They are as follows:

- `-fimf-precision` (Linux* and macOS*) or `/Qimf-precision` (Windows*)
- `-fimf-max-error` (Linux* and macOS*) or `/Qimf-max-error` (Windows*)
- `-fimf-accuracy-bits` (Linux and macOS*) or `/Qimf-accuracy-bits` (Windows)

If more than one of these options are specified, the default value for the maximum relative error is determined by the last one specified on the command line.

If none of the above options are specified, the default values for the maximum relative error are determined by the setting of the following options:

- `[Q]fast-transcendentals`
- `[Q]prec-div`
- `[Q]prec-sqrt`
- `-fp-model` (Linux and macOS*) or `/fp` (Windows)

NOTE
Many routines in libraries LIBM (Math Library) and SVML (Short Vector Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

NOTE
The standard Fortran names for the various math intrinsic functions *do not* match the math library names of the math intrinsic functions. You must find the actual math library name that is generated for the relevant Fortran math intrinsic.

One way to do this is to generate assembly code by using options `/Fa` or `/S` on Windows, or option `-S` on Linux. The assembly code will show the actual math library name.

For example, if you create a program that contains a call to SIN(x) where x is declared as REAL(KIND=4) and then use option `/S` on Windows to produce assembly code for the program, the assembly code will show a call to sinf.

Therefore, to define the maximum allowable relative error for the single-precision sine function, you would specify `-fimf-max-error=sinf` (or `/Qimf-max-error:sinf`).

fimf-precision, Qimf-precision

Lets you specify a level of accuracy (precision) that the compiler should use when determining which math library functions to use.

Syntax

Linux OS:

`-fimf-precision[=value[:funclist]]`

macOS:

`-fimf-precision[=value[:funclist]]`

Windows OS:

`/Qimf-precision[:value[:funclist]]`

Arguments

value

Is one of the following values denoting the desired accuracy:

`high`	This is equivalent to max-error = 1.0.
`medium`	This is equivalent to max-error = 4; this is the default setting if the option is specified and *value* is omitted.
`low`	This is equivalent to accuracy-bits = 11 for single-precision functions; accuracy-bits = 26 for double-precision functions.

In the above explanations, max-error means option `-fimf-max-error` (Linux* and macOS*) or `/Qimf-max-error` (Windows*); accuracy-bits means option `-fimf-accuracy-bits` (Linux* and macOS*) or `/Qimf-accuracy-bits` (Windows*).

funclist

Is an optional list of one or more math library functions to which the attribute should be applied. Do not specify the standard Fortran name of the math function; you must specify the actual math library name. If you specify more than one function, they must be separated with commas.

Precision-specific variants like sin and sinf are considered different functions, so you would need to use `-fimf-precision=high:sin,sinf` (or `/Qimf-precision:high:sin,sinf`) to specify high precision for both the single-precision and double-precision sine functions.

You also can specify the symbol /f to denote single-precision divides, symbol / to denote double-precision divides, symbol /l to denote extended-precision divides, and symbol /q to denote quad-precision divides. For example you can specify `-fimf-precision=low:/` or `/Qimf-precision:low:/` and `-fimf-precision=low:/f` or `/Qimf-precision:low:/f`.

Default

medium The compiler uses medium precision when calling math library functions. Note that other options can affect precision; see below for details.

Description

This option lets you specify a level of accuracy (precision) that the compiler should use when determining which math library functions to use.

This option can be used to improve run-time performance if reduced accuracy is sufficient for the application, or it can be used to increase the accuracy of math library functions selected by the compiler.

In general, using a lower precision can improve run-time performance and using a higher precision may reduce run-time performance.

If you need to define the accuracy for a math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sinf, as in `-fimf-precision=low:sin` or `/Qimf-precision:low:sin`, or `-fimf-precision=high:sqrtf` or `/Qimf-precision:high:sqrtf`.

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, sinf applies only to the single-precision sine function, sin applies only to the double-precision sine function, sinl applies only to the extended-precision sine function, etc.

There are three options you can use to express the maximum relative error. They are as follows:

- `-fimf-precision` (Linux* and macOS*) or `/Qimf-precision` (Windows*)
- `-fimf-max-error` (Linux* and macOS*) or `/Qimf-max-error` (Windows*)
- `-fimf-accuracy-bits` (Linux and macOS*) or `/Qimf-accuracy-bits` (Windows)

If more than one of these options are specified, the default value for the maximum relative error is determined by the last one specified on the command line.

If none of the above options are specified, the default values for the maximum relative error are determined by the setting of the following options:

- `[Q]fast-transcendentals`
- `[Q]prec-div`
- `[Q]prec-sqrt`
- `-fp-model` (Linux and macOS*) or `/fp` (Windows)

NOTE
Many routines in libraries LIBM (Math Library) and SVML (Short Vector Math Library) are more highly optimized for Intel® microprocessors than for non-Intel microprocessors.

NOTE
The standard Fortran names for the various math intrinsic functions *do not* match the math library names of the math intrinsic functions. You must find the actual math library name that is generated for the relevant Fortran math intrinsic.

One way to do this is to generate assembly code by using options `/Fa` or `/S` on Windows, or option `-S` on Linux. The assembly code will show the actual math library name.

For example, if you create a program that contains a call to SIN(x) where x is declared as REAL(KIND=4) and then use option `/S` on Windows to produce assembly code for the program, the assembly code will show a call to sinf.

Therefore, to specify a level of accuracy for the single-precision sine function, you would specify `-fimf-precision=sinf` (or `/Qimf-precision:sinf`).

`fimf-use-svml_Qimf-use-svml` compiler option

fimf-use-svml, Qimf-use-svml

Instructs the compiler to use the Short Vector Math Library (SVML) rather than the Intel® Math Library (LIBM) to implement math library functions.

Syntax

Linux OS:

`-fimf-use-svml=`*value*`[:`*funclist*`]`

macOS:

`-fimf-use-svml=`*value*`[:`*funclist*`]`

Windows OS:

`/Qimf-use-svml:`*value*`[:`*funclist*`]`

Arguments

funclist	Is an optional list of one or more math library functions to which the attribute should be applied. Do not specify the standard Fortran name of the math function; you must specify the actual math library name. If you specify more than one function, they must be separated with commas. Precision-specific variants like sin and sinf are considered different functions, so you would need to use `-fimf-use-svmlt=true:sin,sinf` (or `/Qimf-use-svml:true:sin,sinf`) to specify that both the single-precision and double-precision sine functions should use SVML.

Default

false	Math library functions are implemented using the Intel® Math Library, though other compiler options such as `-fast-transcendentals` or `/Qfast-transcendentals` may give the compiler the flexibility to implement math library functions with either LIBM or SVML.

Description

This option instructs the compiler to implement math library functions using the Short Vector Math Library (SVML). When you specify `-fimf-use-svml=true` or `/Qimf-use-svml:true`, the specific SVML variant chosen is influenced by other compiler options such as `-fimf-precision` (Linux* and macOS*) or `/Qimf-precision` (Windows*) and `-fp-model` (Linux and macOS*) or `/fp` (Windows). This option has no effect on math library functions that are implemented in LIBM but not in SVML.

In value-safe settings of option `-fp-model` (Linux and macOS*) or option `/fp` (Windows) such as precise, this option causes a slight decrease in the accuracy of math library functions, because even the high accuracy SVML functions are slightly less accurate than the corresponding functions in LIBM. Additionally, the SVML functions might not accurately raise floating-point exceptions, do not maintain errno, and are designed to work correctly only in round-to-nearest-even rounding mode.

The benefit of using `-fimf-use-svml=true` or `/Qimf-use-svml:true` with value-safe settings of `-fp-model` (Linux and macOS*) or /fp (Windows) is that it can significantly improve performance by enabling the compiler to efficiently vectorize loops containing calls to math library functions.

If you need to use SVML for a specific math function of a certain precision, specify the function name of the precision that you need. For example, if you want double precision, you can specify :sin; if you want single precision, you can specify :sqrtf, as in `-fimf-use-svml=true:sin` or `/Qimf-use-svml:true:sin`, or `-fimf-use-svml =false:sqrtf` or `/Qimf-use-svml:false:sqrtf`.

If you do not specify any function names, then the setting applies to all functions (and to all precisions). However, as soon as you specify an individual function name, the setting applies only to the function of corresponding precision. So, for example, sinf applies only to the single-precision sine function, sin applies only to the double-precision sine function, sinl applies only to the extended-precision sine function, etc.

NOTE
If you specify option `-mia32` (Linux*) or option `/arch:IA32` (Windows*), vector instructions cannot be used. Therefore, you cannot use Linux* option `-mia32` with option `-fimf-use-svml=true`, and you cannot use Windows* option `/arch:IA32` with option `/Qimf-use-svml:true`.

NOTE
Since SVML functions may raise unexpected floating-point exceptions, be cautious about using features that enable trapping on floating-point exceptions. For example, be cautious about specifying option `-fimf-use-svml=true` with option `-fp-trap`, or option `/Qimf-use-svml:true` with option `/Qfp-trap`. For some inputs to some math library functions, such option combinations may cause your program to trap unexpectedly.

NOTE
The standard Fortran names for the various math intrinsic functions *do not* match the math library names of the math intrinsic functions. You must find the actual math library name that is generated for the relevant Fortran math intrinsic.

One way to do this is to generate assembly code by using options `/Fa` or `/S` on Windows, or option `-S` on Linux. The assembly code will show the actual math library name.

For example, if you create a program that contains a call to SIN(x) where x is declared as REAL(KIND=4) and then use option `/S` on Windows to produce assembly code for the program, the assembly code will show a call to sinf.

Therefore, to request the use of SVML for the single-precision sine function, you would specify `-fimf-use-svml=true: sinf` (or `/Qimf-use-svml:true: sinf`).

fltconsistency

Enables improved floating-point consistency.

Syntax

Linux OS and macOS:

```
-fltconsistency
-nofltconsistency
```

Windows OS:

```
/fltconsistency
/nofltconsistency
```

Arguments

None

Default

`nofltconsistency` Improved floating-point consistency is not enabled. This setting provides better accuracy and run-time performance at the expense of less consistent floating-point results.

Description

This option enables improved floating-point consistency and may slightly reduce execution speed. It limits floating-point optimizations and maintains declared precision. It also disables inlining of math library functions.

Floating-point operations are not reordered and the result of each floating-point operation is stored in the target variable rather than being kept in the floating-point processor for use in a subsequent calculation.

For example, the compiler can change floating-point division computations into multiplication by the reciprocal of the denominator. This change can alter the results of floating-point division computations slightly.

Floating-point intermediate results are kept in full 80 bits internal precision. Additionally, all spills/reloads of the X87 floating point registers are done using the internal formats; this prevents accidental loss of precision due to spill/reload behavior over which you have no control.

Specifying this option has the following effects on program compilation:

- Floating-point user variables are not assigned to registers.
- Floating-point arithmetic comparisons conform to IEEE 754.
- The exact operations specified in the code are performed. For example, division is never changed to multiplication by the reciprocal.
- The compiler performs floating-point operations in the order specified without reassociation.

- The compiler does not perform constant folding on floating-point values. Constant folding also eliminates any multiplication by 1, division by 1, and addition or subtraction of 0. For example, code that adds 0.0 to a number is executed exactly as written. Compile-time floating-point arithmetic is not performed to ensure that floating-point exceptions are also maintained.
- Whenever an expression is spilled, it is spilled as 80 bits (extended precision), not 64 bits (DOUBLE PRECISION). When assignments to type REAL and DOUBLE PRECISION are made, the precision is rounded from 80 bits down to 32 bits (REAL) or 64 bits (DOUBLE PRECISION). When you do not specify `/fltconsistency`, the extra bits of precision are not always rounded away before the variable is reused.
- Even if vectorization is enabled by the `[Q]x` option, the compiler does not vectorize reduction loops (loops computing the dot product) and loops with mixed precision types. Similarly, the compiler does not enable certain loop transformations. For example, the compiler does not transform reduction loops to perform partial summation or loop interchange.

This option causes performance degradation relative to using default floating-point optimization flags.

On Windows systems, an alternative is to use the `/Qprec` option, which should provide better than default floating-point precision while still delivering good floating-point performance.

The recommended method to control the semantics of floating-point calculations is to use option `-fp-model` (Linux* and macOS*) or `/fp` (Windows*).

IDE Equivalent

`mp1, Qprec` compiler option
`fp-model, fp` compiler option

fma, Qfma

Determines whether the compiler generates fused multiply-add (FMA) instructions if such instructions exist on the target processor.

Syntax

Linux OS:

`-fma`

`-no-fma`

macOS:

`-fma`

`-no-fma`

Windows OS:

`/Qfma`

`/Qfma-`

Arguments

None

Default

`-fma` or `/Qfma`	If the instructions exist on the target processor, the compiler generates fused multiply-add (FMA) instructions. However, if you specify `-fp-model strict` (Linux* and macOS*) or `/fp:strict` (Windows*), but do not explicitly specify `-fma` or `/Qfma`, the default is `-no-fma` or `/Qfma-`.

Description

This option determines whether the compiler generates fused multiply-add (FMA) instructions if such instructions exist on the target processor. When the `[Q]fma` option is specified, the compiler may generate FMA instructions for combining multiply and add operations. When the negative form of the `[Q]fma` option is specified, the compiler must generate separate multiply and add instructions with intermediate rounding.

This option has no effect unless setting CORE-AVX2 or higher is specified for option [Q]x,`-march` (Linux and macOS*), or `/arch` (Windows).

IDE Equivalent

None

fp-model, fp

Controls the semantics of floating-point calculations.

Syntax

Linux OS:

`-fp-model` *keyword*

macOS:

`-fp-model` *keyword*

Windows OS:

`/fp:`*keyword*

Arguments

keyword	Specifies the semantics to be used. Possible values are:

`precise`	Disables optimizations that are not value-safe on floating-point data and rounds intermediate results to source-defined precision.
`fast[=1|2]`	Enables more aggressive optimizations on floating-point data.
`consistent`	The compiler uses default heuristics to determine results for different optimization levels or between different processors of the same architecture.
`strict`	Enables precise and except, disables contractions, and enables the property that allows modification of the floating-point environment.
`source`	Rounds intermediate results to source-defined precision.
`[no-]except` (Linux* and macOS*) or `except[-]` (Windows*)	Determines whether strict floating-point exception semantics are honored.

Default

`-fp-model fast=1` or `/fp:fast=1`	The compiler uses more aggressive optimizations on floating-point calculations.

Description

This option controls the semantics of floating-point calculations.

The *keywords* can be considered in groups:

- Group A: `precise`, `fast`, `strict`
- Group B: `source`
- Group C: `except` (or negative forms `-no-except` or `/except-`)
- Group D: `consistent`

You can specify more than one *keyword*. However, the following rules apply:

- You cannot specify `fast` and `except` together in the same compilation. You can specify any other combination of group A, group B, and group C.
  Since `fast` is the default, you must not specify `except` without a group A or group B *keyword*.
- You should specify only one *keyword* from group A and only one *keyword* from group B. If you try to specify more than one *keyword* from either group A or group B, the last (rightmost) one takes effect.
- If you specify `except` more than once, the last (rightmost) one takes effect.
- If you specify `consistent` and any other keyword from another group, the last (rightmost) one may not fully override the heuristics set by `consistent`.

The floating-point (FP) environment is a collection of registers that control the behavior of FP machine instructions and indicate the current FP status. The floating-point environment may include rounding-mode controls, exception masks, flush-to-zero controls, exception status flags, and other floating-point related features.

Option	Description
`-fp-model precise` or `/fp:precise`	Tells the compiler to strictly adhere to value-safe optimizations when implementing floating-point calculations. It disables optimizations that can change the result of floating-point calculations. These semantics ensure the reproducibility of floating-point computations for serial code, including code vectorized or auto-parallelized by the compiler, but they may slow performance. They do not ensure value safety or run-to-run reproducibility of other parallel code. Run-to-run reproducibility for floating-point reductions in OpenMP* code may be obtained for a fixed number of threads through the KMP_DETERMINISTIC_REDUCTION environment variable. For more information about this environment variable, see topic "Supported Environment Variables". The compiler assumes the default floating-point environment; you are not allowed to modify it. Note that option `fp-model precise` implies `fp-model source` and option `fp:precise` implies `fp:source`. Floating-point exception semantics are disabled by default. To enable these semantics, you must also specify `-fp-model except` or `/fp:except`.
`-fp-model fast[=1|2]` or `/fp:fast[=1|2]`	Tells the compiler to use more aggressive optimizations when implementing floating-point calculations. These optimizations increase speed, but may affect the accuracy or reproducibility of floating-point computations. Specifying fast is the same as specifying `fast=1`. `fast=2` may produce faster and less accurate results. Floating-point exception semantics are disabled by default and they cannot be enabled because you cannot specify fast and except together in the same compilation. To enable exception semantics, you must explicitly specify another keyword (see other keyword descriptions for details). To enable exception semantics, you must explicitly specify another keyword (see other keyword descriptions for details).
`-fp-model consistent` or `/fp:consistent`	The compiler uses default heuristics to generate code that will determine results for different optimization levels or between different processors of the same architecture .

Option	Description
	For more information, see the article titled: *Consistency of Floating-Point Results using the Intel® Compiler*, which is located in http://software.intel.com/en-us/articles/consistency-of-floating-point-results-using-the-intel-compiler/
`-fp-model source` or `/fp:source`	This option causes intermediate results to be rounded to the precision defined in the source code. It also implies keyword `precise` unless it is overridden by a keyword from Group A. The compiler assumes the default floating-point environment; you are not allowed to modify it.
`-fp-model except` or `/fp:except`	Tells the compiler to follow strict floating-point exception semantics.

The `-fp-model` and `/fp` options determine the setting for the maximum allowable relative error for math library function results (max-error) if none of the following options are specified:

- `-fimf-accuracy-bits` (Linux* and macOS*) or `/Qimf-accuracy-bits` (Windows*)
- `-fimf-max-error` (Linux and macOS*) or `/Qimf-max-error` (Windows)
- `-fimf-precision` (Linux and macOS*) or `/Qimf-precision` (Windows)
- `[Q]fast-transcendentals`

Option `-fp-model fast` (and `/fp:fast`) sets option `-fimf-precision=medium` (`/Qimf-precision:medium`) and option `-fp-model precise` (and `/fp:precise`) implies `-fimf-precision=high` (and `/Qimf-precision:high`). Option `-fp-model fast=2` (and `/fp:fast2`) sets option `-fimf-precision=medium` (and `/Qimf-precision:medium`) and option `-fimf-domain-exclusion=15` (and `/Qimf-domain-exclusion=15`).

NOTE
This option cannot be used to change the default (source) precision for the calculation of intermediate results.

NOTE
In Microsoft* Visual Studio, when you create a Visual Studio* Fortran project, option `/fp:fast` is set by default. It sets the floating-point model to use more aggressive optimizations when implementing floating-point calculations, which increase speed, but may affect the accuracy or reproducibility of floating-point computations. `/fp:fast` is the general default for the IDE project property for Floating Point Model.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain

Optimization Notice
optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice. Notice revision #20110804

fp-port, Qfp-port

Rounds floating-point results after floating-point operations.

Syntax

Linux OS:

```
-fp-port
-no-fp-port
```

macOS:

```
-fp-port
-no-fp-port
```

Windows OS:

```
/Qfp-port
/Qfp-port-
```

Arguments

None

Default

`-no-fp-port` or `/Qfp-port-`	The default rounding behavior depends on the compiler's code generation decisions and the precision parameters of the operating system.

Description

This option rounds floating-point results after floating-point operations.

This option is designed to be used with the `-mia32` (Linux*) or `/arch:IA32` (Windows*) option on a 32-bit compiler. Under those conditions, the compiler implements floating-point calculations using the x87 instruction set, which uses an internal precision that may be higher than the precision specified in the program.

By default, the compiler may keep results of floating-point operations in this higher internal precision. Rounding to program precision occurs at unspecified points. This provides better performance, but the floating-point results are less deterministic. The `[Q]fp-port` option rounds floating-point results to user-specified precision at assignments and type conversions. This has some impact on speed.

When compiling for newer architectures, the compiler implements floating-point calculations with different instructions, such as Intel® SSE and SSE2. These Intel® Streaming SIMD Extensions round directly to single precision or double precision at every instruction. In these cases, option `[Q]fp-port` has no effect.

IDE Equivalent

Visual Studio: **Floating-Point > Round Floating-Point Results**

Eclipse: None

Xcode: **Floating-Point > Round Floating-Point Results**

Alternate Options

Understanding Floating-point Operations

fp-speculation, Qfp-speculation

Tells the compiler the mode in which to speculate on floating-point operations.

Syntax

Linux OS:

`-fp-speculation=`*mode*

macOS:

`-fp-speculation=`*mode*

Windows OS:

`/Qfp-speculation:`*mode*

Arguments

mode	Is the mode for floating-point operations. Possible values are:

`fast`	Tells the compiler to speculate on floating-point operations.
`safe`	Tells the compiler to disable speculation if there is a possibility that the speculation may cause a floating-point exception.
`strict`	Tells the compiler to disable speculation on floating-point operations.
`off`	This is the same as specifying strict.

Default

`-fp-speculation=fast` or `/Qfp-speculation:fast`	The compiler speculates on floating-point operations. This is also the behavior when optimizations are enabled. However, if you specify no optimizations (`-O0` on Linux*; `/Od` on Windows*), the default is `-fp-speculation=safe` (Linux*) or `/Qfp-speculation:safe` (Windows*).

Description

This option tells the compiler the mode in which to speculate on floating-point operations.

Disabling speculation may prevent the vectorization of some loops containing conditionals. For an example, see the article titled: *Diagnostic 15326: loop was not vectorized: implied FP exception model prevents vectorization*, which is located in https://software.intel.com/en-us/articles/fdiag15326 .

IDE Equivalent

Visual Studio: **Floating Point > Floating-Point Speculation**

Eclipse: None

Xcode: **Floating Point > Floating-Point Speculation**

Alternate Options

None

fp-stack-check, Qfp-stack-check

Tells the compiler to generate extra code after every function call to ensure that the floating-point stack is in the expected state.

Syntax

Linux OS and macOS:

`-fp-stack-check`

Windows OS:

`/Qfp-stack-check`

Arguments

None

Default

OFF	There is no checking to ensure that the floating-point (FP) stack is in the expected state.

Description

This option tells the compiler to generate extra code after every function call to ensure that the floating-point (FP) stack is in the expected state.

By default, there is no checking. So when the FP stack overflows, a NaN value is put into FP calculations and the program's results differ. Unfortunately, the overflow point can be far away from the point of the actual bug. This option places code that causes an access violation exception immediately after an incorrect call occurs, thus making it easier to locate these issues.

IDE Equivalent

Visual Studio: **Floating-Point > Check Floating-Point Stack**

Eclipse: None

Xcode: **Floating-Point > Check Floating-point Stack**

Alternate Options

None

fpe

Allows some control over floating-point exception handling for the main program at run-time.

Syntax

Linux OS and macOS:

`-fpe`*n*

Windows OS:

`/fpe:`*n*

Arguments

n Specifies the floating-point exception handling level. Possible values are:

`0` Floating-point invalid, divide-by-zero, and overflow exceptions are enabled throughout the application when the main program is compiled with this value. If any such exceptions occur, execution is aborted. This option causes subnormal floating-point results to be set to zero. Underflow results will also be set to zero, unless you override this by explicitly specifying option `-no-ftz` or `-fp-model precise` (Linux* and macOS*) or option `/Qftz-` or `/fp:precise` (Windows*).

Underflow results from SSE instructions, as well as x87 instructions, will be set to zero. By contrast, option `[Q]ftz` only sets SSE underflow results to zero.

Sets option `-fp-speculation=strict` (Linux* and macOS*) or `/Qfp-speculation:strict` (Windows*) for any program unit compiled with `-fpe0` (Linux* and macOS*) or `/fpe:0` (Windows*). This disables certain optimizations in cases where speculative execution of floating-point operations could lead to floating-point exceptions that would not occur in the absence of speculation. For example, this may prevent the vectorization of some loops containing conditionals.

Disables certain optimizations that generate calls to the Short Vector Math Library that could lead to floating-point exceptions for extreme input arguments that would not occur if libm was called instead. For example, this may prevent the vectorization of some loops containing calls to transcendental math functions.

To get more detailed location information about where the error occurred, use option `traceback`.

`1` All floating-point exceptions are disabled.

Underflow results from SSE instructions, as well as x87 instructions, will be set to zero.

`3` All floating-point exceptions are disabled. Floating-point underflow is gradual, unless you explicitly specify a compiler option that enables flush-to-zero, such as `[Q]ftz`, `O3`, or `O2`. This setting provides full IEEE support.

Default

`-fpe3` or `/fpe:3` All floating-point exceptions are disabled. Floating-point underflow is gradual, unless you explicitly specify a compiler option that enables flush-to-zero.

Description

This option allows some control over floating-point exception handling at run-time. This includes whether exceptional floating-point values are allowed and how precisely run-time exceptions are reported.

The `fpe` option affects how the following conditions are handled:

- When floating-point calculations result in a divide by zero, overflow, or invalid operation.
- When floating-point calculations result in an underflow.
- When a subnormal number or other exceptional number (positive infinity, negative infinity, or a NaN) is present in an arithmetic expression.

When enabled exceptions occur, execution is aborted and the cause of the abort reported to the user. If compiler option `traceback` is specified at compile time, detailed information about the location of the abort is also reported.

This option does not enable underflow exceptions, input subnormal exceptions, or inexact exceptions.

IDE Equivalent

Visual Studio: **Floating-Point > Floating-Point Exception Handling**

Eclipse: None

Xcode: **Floating-Point > Floating-Point Exception Handling**

Alternate Options

None

See Also

`fpe-all` compiler option

fpe-all

Allows some control over floating-point exception handling for each routine in a program at run-time.

Syntax

Linux OS and macOS:

`-fpe-all=`*n*

Windows OS:

`/fpe-all:`*n*

Arguments

n Specifies the floating-point exception handling level. Possible values are:

`0` Floating-point invalid, divide-by-zero, and overflow exceptions are enabled. If any such exceptions occur, execution is aborted. This option sets the `[Q]ftz` option; therefore underflow results will be set to zero unless you explicitly specify `-no-ftz` (Linux and macOS*) or `/Qftz-` (Windows).

To get more detailed location information about where the error occurred, use option `traceback`.

`1` All floating-point exceptions are disabled.

Underflow results from SSE instructions, as well as x87 instructions, will be set to zero.

`3` All floating-point exceptions are disabled. Floating-point underflow is gradual, unless you explicitly specify a compiler option that enables flush-to-zero, such as [Q]ftz, `O3`, or `O2`. This setting provides full IEEE support.

Default

`-fpe-all=3` All floating-point exceptions are disabled. Floating-point underflow is gradual, unless you explicitly specify a compiler option that enables flush-to-zero.

or `/fpe-all:3`

or the setting of `fpe` that the main program was compiled with

Description

This option allows some control over floating-point exception handling for each routine in a program at run-time. This includes whether exceptional floating-point values are allowed and how precisely run-time exceptions are reported.

The `fpe-all` option affects how the following conditions are handled:

- When floating-point calculations result in a divide by zero, overflow, or invalid operation.
- When floating-point calculations result in an underflow.
- When a subnormal number or other exceptional number (positive infinity, negative infinity, or a NaN) is present in an arithmetic expression.

The current settings of the floating-point exception and status flags are saved on each routine entry and restored on each routine exit. This may incur some performance overhead.

When option `fpe-all` is applied to a main program, it has the same effect as when option `fpe` is applied to the main program.

When enabled exceptions occur, execution is aborted and the cause of the abort reported to the user. If compiler option `traceback` is specified at compile time, detailed information about the location of the abort is also reported.

This option does not enable underflow exceptions, input subnormal exceptions, or inexact exceptions.

Option `fpe-all` sets option `assume ieee_fpe_flags`.

IDE Equivalent

None

Alternate Options

None

See Also

`assume` compiler option
`fpe` compiler option

`traceback` compiler option

ftz, Qftz

Flushes subnormal results to zero.

Syntax

Linux OS and macOS:

`-ftz`

`-no-ftz`

Windows OS:

`/Qftz`

`/Qftz-`

Arguments

None

Default

`-ftz` or `/Qftz`	Subnormal results are flushed to zero. Every optimization option `O` level, except `O0`, sets `[Q]ftz`. Value 0 for the `[Q]fpe` option sets `[Q]ftz`.

Description

This option flushes subnormal results to zero when the application is in the gradual underflow mode. It may improve performance if the subnormal values are not critical to your application's behavior.

The `[Q]ftz` option has no effect during compile-time optimization.

The [Q]ftz option sets or resets the FTZ and the DAZ hardware flags. If FTZ is ON, subnormal results from floating-point calculations will be set to the value zero. If FTZ is OFF, subnormal results remain as is. If DAZ is ON, subnormal values used as input to floating-point instructions will be treated as zero. If DAZ is OFF, subnormal instruction inputs remain as is. Systems using Intel® 64 architecture have both FTZ and DAZ. FTZ and DAZ are not supported on all IA-32 architectures.

When the [Q]ftz option is used in combination with an SSE-enabling option on systems using IA-32 architecture (for example, the [Q]xSSE2 option), the compiler will insert code in the main routine to set FTZ and DAZ. When [Q]ftz is used without such an option, the compiler will insert code to conditionally set FTZ/DAZ based on a run-time processor check.

If you specify option -no-ftz (Linux and macOS*) or option /Qftz- (Windows), it prevents the compiler from inserting any code that might set FTZ or DAZ.

Option [Q]ftz only has an effect when the main program is being compiled. It sets the FTZ/DAZ mode for the process. The initial thread and any threads subsequently created by that process will operate in FTZ/DAZ mode.

If this option produces undesirable results of the numerical behavior of your program, you can turn the FTZ/DAZ mode off by specifying -no-ftz or /Qftz- in the command line while still benefiting from the O3 optimizations.

NOTE
Option [Q]ftz is a performance option. Setting this option does not guarantee that all subnormals in a program are flushed to zero. The option only causes subnormals generated at run time to be flushed to zero.

IDE Equivalent

Visual Studio: IA-32 architecture: **Floating Point > Flush Subnormal Results to Zero**

Intel® 64 architecture: None

Eclipse: None

Xcode: **Floating Point > Flush Subnormal Results to Zero**

Alternate Options

x, Qx compiler option
Setting the FTZ and DAZ Flags

Ge

Enables stack-checking for all functions. This is a deprecated option. The replacement option is /Gs0.

Syntax

Linux OS and macOS:

None

Windows OS:

/Ge

Arguments

None

Default

OFF Stack-checking for all functions is disabled.

Description

This option enables stack-checking for all functions.

IDE Equivalent

None

Alternate Options

Linux and macOS*: None

Windows: `/Gs0`

mp1, Qprec

Improves floating-point precision and consistency.

Syntax

Linux OS:

`-mp1`

macOS:

`-mp1`

Windows OS:

`/Qprec`

Arguments

None

Default

OFF The compiler provides good accuracy and run-time performance at the expense of less consistent floating-point results.

Description

This option improves floating-point consistency. It ensures the out-of-range check of operands of transcendental functions and improves the accuracy of floating-point compares.

This option prevents the compiler from performing optimizations that change NaN comparison semantics and causes all values to be truncated to declared precision before they are used in comparisons. It also causes the compiler to use library routines that give better precision results compared to the X87 transcendental instructions.

This option disables fewer optimizations and has less impact on performance than option `fltconsistency`.

This option disables fewer optimizations and has less impact on performance than option `fltconsistency`,`-fp-model precise` (Linux* and macOS*), or option `/fp:precise` (Windows*).

IDE Equivalent

Visual Studio: None

Eclipse: None

Xcode: None

Alternate Options

None

See Also

`fltconsistency` compiler option

pc, Qpc

Enables control of floating-point significand precision.

Syntax

Linux OS:

`-pc`*n*

macOS:

`-pc`*n*

Windows OS:

`/Qpc`*n*

Arguments

n	Is the floating-point significand precision. Possible values are:	
	`32`	Rounds the significand to 24 bits (single precision).
	`64`	Rounds the significand to 53 bits (double precision).
	`80`	Rounds the significand to 64 bits (extended precision).

Default

`-pc80` or `/Qpc64`	On Linux* and macOS* systems, the floating-point significand is rounded to 64 bits. On Windows* systems, the floating-point significand is rounded to 53 bits.

Description

This option enables control of floating-point significand precision.

Some floating-point algorithms are sensitive to the accuracy of the significand, or fractional part of the floating-point value. For example, iterative operations like division and finding the square root can run faster if you lower the precision with the this option.

Note that a change of the default precision control or rounding mode, for example, by using the `[Q]pc32` option or by user intervention, may affect the results returned by some of the mathematical functions.

IDE Equivalent

None

Alternate Options

None

prec-div, Qprec-div

Improves precision of floating-point divides.

Syntax

Linux OS and macOS:

`-prec-div`

`-no-prec-div`

Windows OS:

`/Qprec-div`

`/Qprec-div-`

Arguments

None

Default

OFF	Default heuristics are used. The default is not as accurate as full IEEE division, but it is slightly more accurate than would be obtained when `/Qprec-div-` or `-no-prec-div` is specified. If you need full IEEE precision for division, you should specify `[Q]prec-div`.

Description

This option improves precision of floating-point divides. It has a slight impact on speed.

At default optimization levels, the compiler may change floating-point division computations into multiplication by the reciprocal of the denominator. For example, A/B is computed as A * (1/B) to improve the speed of the computation.

However, sometimes the value produced by this transformation is not as accurate as full IEEE division. When it is important to have fully precise IEEE division, use this option to disable the floating-point division-to-multiplication optimization. The result is more accurate, with some loss of performance.

If you specify `-no-prec-div` (Linux* and macOS*) or `/Qprec-div-` (Windows*), it enables optimizations that give slightly less precise results than full IEEE division.

Option `[Q]prec-div` is implied by option `-fp-model precise` (Linux* and macOS*) and option `/fp:precise` (Windows*).

IDE Equivalent

None

Alternate Options

None

See Also

`fp-model, fp` compiler option

prec-sqrt, Qprec-sqrt

Improves precision of square root implementations.

Syntax

Linux OS and macOS:

`-prec-sqrt`

`-no-prec-sqrt`

Windows OS:

`/Qprec-sqrt`

`/Qprec-sqrt-`

Arguments

None

Default

`-no-prec-sqrt` or `/Qprec-sqrt-`	The compiler uses a faster but less precise implementation of square root. However, the default is `-prec-sqrt` or `/Qprec-sqrt` if any of the following options are specified: `/Od`, `/fltconsistency`, or `/Qprec` on Windows* systems; `-O0`, `-fltconsistency`, or `-mp1` on Linux* and macOS* systems.

Description

This option improves precision of square root implementations. It has a slight impact on speed.

This option inhibits any optimizations that can adversely affect the precision of a square root computation. The result is fully precise square root implementations, with some loss of performance.

IDE Equivalent

None

Alternate Options

None

qsimd-honor-fp-model, Qsimd-honor-fp-model

Tells the compiler to obey the selected floating-point model when vectorizing SIMD loops.

Syntax

Linux OS:

`-qsimd-honor-fp-model`

`-qno-simd-honor-fp-model`

macOS:

`-qsimd-honor-fp-model`

`-qno-simd-honor-fp-model`

Windows OS:

`/Qsimd-honor-fp-model`

`/Qsimd-honor-fp-model-`

Arguments

None

Default

`-qno-simd-honor-fp-model` or `/Qsimd-honor-fp-model-`	The compiler performs vectorization of SIMD loops even if it breaks the floating-point model setting.

Description

The OpenMP* SIMD specification and the setting of compiler option `-fp-model` (Linux* and macOS*) or `/fp` (Windows*) can contradict in requirements. When contradiction occurs, the default behavior of the compiler is to follow the OpenMP* specification and therefore vectorize the loop.

This option lets you override this default behavior - it causes the compiler to follow the `-fp-model` (or `/fp`) specification. This means that the compiler will serialize the loop.

> **NOTE**
> This option does not affect automatic vectorization of loops. By default, the compiler uses `-fp-model` (Linux* and macOS*) or `/fp` (Windows*) settings for this.

IDE Equivalent

None

Alternate Options

None

See Also

`qsimd-serialize-fp-reduction, Qsimd-serialize-fp-reduction` compiler option
`fp-model, fp` compiler option
SIMD Loop Directive directive
SIMD Directive (OpenMP* API) directive

qsimd-serialize-fp-reduction, Qsimd-serialize-fp-reduction

Tells the compiler to serialize floating-point reduction when vectorizing SIMD loops.

Syntax

Linux OS:

`-qsimd-serialize-fp-reduction`

`-qno-simd-serialize-fp-reduction`

macOS:

`-qsimd-serialize-fp-reduction`

`-qno-simd-serialize-fp-reduction`

Windows OS:

`/Qsimd-serialize-fp-reduction`

`/Qsimd-serialize-fp-reduction-`

Arguments

None

Default

`-qno-simd-serialize-fp-reduction` or `/Qsimd-serialize-fp-reduction-`	The compiler does not attempt to serialize floating-point reduction in SIMD loops.

Description

The OpenMP* SIMD reduction specification and the setting of compiler option `-fp-model` (Linux* and macOS*) or `/fp` (Windows*) can contradict in requirements. When contradiction occurs, the default behavior of the compiler is to follow OpenMP* specification and therefore vectorize the loop, including floating-point reduction.

This option lets you override this default behavior - it causes the compiler to follow the `-fp-model` (or `/fp`) specification. This means that the compiler will serialize the floating-point reduction while vectorizing the rest of the loop.

NOTE
When `[q or Q]simd-honor-fp-model` is specified and OpenMP* SIMD reduction specification is the only thing causing serialization of the entire loop, addition of option `[q or Q]simd-serialize-fp-reduction` will result in vectorization of the entire loop except for reduction calculation, which will be serialized.

NOTE
This option does not affect automatic vectorization of loops. By default, the compiler uses `-fp-model` (Linux* and macOS*) or `/fp` (Windows*) settings for this.

IDE Equivalent

None

Alternate Options

None

SIMD Directive (OpenMP* API) directive

rcd, Qrcd

Enables fast float-to-integer conversions. This is a deprecated option. There is no replacement option.

Syntax

Linux OS:

`-rcd`

macOS:

`-rcd`

Windows OS:

`/Qrcd`

Arguments

None

Default

OFF Floating-point values are truncated when a conversion to an integer is involved.

Description

This option enables fast float-to-integer conversions. It can improve the performance of code that requires floating-point-to-integer conversions.

The system default floating-point rounding mode is round-to-nearest. However, the Fortran language requires floating-point values to be truncated when a conversion to an integer is involved. To do this, the compiler must change the rounding mode to truncation before each floating-point-to-integer conversion and change it back afterwards.

This option disables the change to truncation of the rounding mode for all floating-point calculations, including floating point-to-integer conversions. This option can improve performance, but floating-point conversions to integer will not conform to Fortran semantics.

IDE Equivalent

None

Alternate Options

Linux and macOS*: None

Windows: `/QIfist` (this is a deprecated option)

recursive

Tells the compiler that all routines should be compiled for possible recursive execution.

Syntax

Linux OS and macOS:

`-recursive`

`-norecursive`

Windows OS:

`/recursive`

`/norecursive`

Arguments

None

Default

`norecursive` Routines are not compiled for possible recursive execution.

Description

This option tells the compiler that all routines should be compiled for possible recursive execution. It sets the `automatic` option.

> **NOTE**
> This option will be deprecated in a future release. We recommend you use its replacement option: `assume [no]recursion`.

IDE Equivalent

Visual Studio: **Code Generation > Enable Recursive Routines**

Eclipse: None

Xcode: **Code Generation > Enable Recursive Routines**

Alternate Options

Linux and macOS*: `-assume [no]recursion`

Windows: `/assume:[no]recursion`

See Also

`auto` compiler option

`assume` compiler option, setting [no]recursion

Inlining Options

finline

Tells the compiler to inline functions declared with !DIR$ ATTRIBUTES FORCEINLINE.

Syntax

Linux OS:

`-finline`

`-fno-inline`

macOS:

`-finline`

`-fno-inline`

Windows OS:

None

Arguments

None

Default

`-fno-inline`	The compiler does not inline functions declared with !DIR$ ATTRIBUTES FORCEINLINE.

Description

This option tells the compiler to inline functions declared with !DIR$ ATTRIBUTES FORCEINLINE.

IDE Equivalent

None

Alternate Options

Linux and macOS*: `-inline-level`

Windows: `/Ob`

finline-functions

Enables function inlining for single file compilation.

Syntax

Linux OS:

`-finline-functions`

`-fno-inline-functions`

macOS:

`-finline-functions`

`-fno-inline-functions`

Windows OS:

None

Arguments

None

Default

`-finline-functions`	Interprocedural optimizations occur. However, if you specify `-O0`, the default is OFF.

Description

This option enables function inlining for single file compilation.

It enables the compiler to perform inline function expansion for calls to functions defined within the current source file.

The compiler applies a heuristic to perform the function expansion. To specify the size of the function to be expanded, use the `-finline-limit` option.

IDE Equivalent

None

Alternate Options

Linux and macOS*: `-inline-level=2`

Windows: `/Ob2`

See Also

`ip, Qip` compiler option

`finline-limit` compiler option

finline-limit

Lets you specify the maximum size of a function to be inlined.

Syntax

Linux OS and macOS:

`-finline-limit=`*n*

Windows OS:

`None`

Arguments

n	Must be an integer greater than or equal to zero. It is the maximum number of lines the function can have to be considered for inlining.

Default

OFF	The compiler uses default heuristics when inlining functions.

Description

This option lets you specify the maximum size of a function to be inlined. The compiler inlines smaller functions, but this option lets you inline large functions. For example, to indicate a large function, you could specify 100 or 1000 for *n*.

Note that parts of functions cannot be inlined, only whole functions.

This option is a modification of the `-finline-functions` option, whose behavior occurs by default.

IDE Equivalent

None

Alternate Options

None

See Also

`finline-functions` compiler option

inline

Specifies the level of inline function expansion.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/inline[:keyword]`

Arguments

keyword Is the level of inline function expansion. Possible values are:

`none` Disables inlining of user-defined functions. This is the same as specifying `manual`.

`manual` Disables inlining of user-defined functions. Fortran statement functions are always inlined.

size Enables inlining of any function. However, the compiler decides which functions are inlined.

This option enables interprocedural optimizations and most speed optimizations.

`speed` Enables inlining of any function. This is the same as specifying `all`.

`all` Enables inlining of any function. However, the compiler decides which functions are inlined.

This option enables interprocedural optimizations and all speed optimizations. This is the same as specifying `inline` with no *keyword*.

Default

OFF The compiler inlines certain functions by default.

Description

This option specifies the level of inline function expansion.

IDE Equivalent

None

Alternate Options

`inline all`
or
`inline speed` Linux and macOS*: None
Windows: `/Ob2/Ot`

`inline size` Linux and macOS*: None
Windows: `/Ob2/Os`

`inline manual` Linux and macOS*: None
Windows: `/Ob0`

`inline none` Linux and macOS*: None
Windows: `/Ob0`

See Also

`finline-functions` compiler option

inline-factor, Qinline-factor

Specifies the percentage multiplier that should be applied to all inlining options that define upper limits.

Syntax

Linux OS and macOS:

`-inline-factor=`*n*

`-no-inline-factor`

Windows OS:

`/Qinline-factor:`*n*

`/Qinline-factor-`

Arguments

n	Is a positive integer specifying the percentage value. The default value is 100 (a factor of 1).

Default

`-inline-factor=100` or `/Qinline-factor:100`	The compiler uses a percentage multiplier of 100.

Description

This option specifies the percentage multiplier that should be applied to all inlining options that define upper limits:

- `[Q]inline-max-size`
- `[Q]inline-max-total-size`
- `[Q]inline-max-per-routine`
- `[Q]inline-max-per-compile`

The `[Q]inline-factor` option takes the default value for each of the above options and multiplies it by *n* divided by 100. For example, if 200 is specified, all inlining options that define upper limits are multiplied by a factor of 2. This option is useful if you do not want to individually increase each option limit.

If you specify `-no-inline-factor` (Linux* and macOS*) or `/Qinline-factor-` (Windows*), the following occurs:

- Every function is considered to be a small or medium function; there are no large functions.
- There is no limit to the size a routine may grow when inline expansion is performed.
- There is no limit to the number of times some routine may be inlined into a particular routine.
- There is no limit to the number of times inlining can be applied to a compilation unit.

To see compiler values for important inlining limits, specify option `[q or Q]opt-report`.

Caution
When you use this option to increase default limits, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

IDE Equivalent

None

Alternate Options

None

`qopt-report, Qopt-report` compiler option

inline-forceinline, Qinline-forceinline

Instructs the compiler to force inlining of functions suggested for inlining whenever the compiler is capable doing so.

Syntax

Linux OS and macOS:

`-inline-forceinline`

Windows OS:

`/Qinline-forceinline`

Default

OFF The compiler uses default heuristics for inline routine expansion.

Description

This option instructs the compiler to force inlining of functions suggested for inlining whenever the compiler is capable doing so.

Without this option, the compiler treats functions declared with an INLINE attribute as merely being recommended for inlining. When this option is used, it is as if they were declared with the directive !DIR$ ATTRIBUTES FORCEINLINE.

To see compiler values for important inlining limits, specify option `[q or Q]opt-report`.

Caution
When you use this option to change the meaning of inline to "forceinline", the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

IDE Equivalent

None

Alternate Options

None

See Also

qopt-report, Qopt-report compiler option

inline-level, Ob

Specifies the level of inline function expansion.

Syntax

Linux OS and macOS:

`-inline-level=n`

Windows OS:

`/Obn`

Arguments

n	Is the inline function expansion level. Possible values are 0, 1, and 2.

Default

`-inline-level=2` or `/Ob2`	This is the default if option `O2` is specified or is in effect by default. On Windows* systems, this is also the default if option `O3` is specified.
`-inline-level=0` or `/Ob0`	This is the default if option `-O0` (Linux* and macOS*) or `/Od` (Windows*) is specified.

Description

This option specifies the level of inline function expansion. Inlining procedures can greatly improve the run-time performance of certain programs.

Option	Description
`-inline-level=0` or `/Ob0`	Disables inlining of user-defined functions. Note that statement functions are always inlined.
`-inline-level=1` or `/Ob1`	Enables inlining when an inline keyword or an inline directive is specified.
`-inline-level=2` or `/Ob2`	Enables inlining of any function at the compiler's discretion.

IDE Equivalent

Visual Studio: **Optimization > Inline Function Expansion**

Eclipse: None

Xcode: **Optimization > Inline Function Expansion**

Alternate Options

None

inline compiler option

inline-max-per-compile, Qinline-max-per-compile

Specifies the maximum number of times inlining may be applied to an entire compilation unit.

Syntax

Linux OS and macOS:

`-inline-max-per-compile=`*n*

`-no-inline-max-per-compile`

Windows OS:

`/Qinline-max-per-compile=`*n*

`/Qinline-max-per-compile-`

Arguments

n	Is a positive integer that specifies the number of times inlining may be applied.

Default

`-no-inline-max-per-compile` or `/Qinline-max-per-compile-`	The compiler uses default heuristics for inline routine expansion.

Description

This option the maximum number of times inlining may be applied to an entire compilation unit. It limits the number of times that inlining can be applied.

For compilations using Interprocedural Optimizations (IPO), the entire compilation is a compilation unit. For other compilations, a compilation unit is a file.

If you specify `-no-inline-max-per-compile` (Linux* and macOS*) or `/Qinline-max-per-compile-` (Windows*), there is no limit to the number of times inlining may be applied to a compilation unit.

To see compiler values for important inlining limits, specify option `[q or Q]opt-report`.

Caution
When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

IDE Equivalent

None

inline-max-per-routine, Qinline-max-per-routine

Specifies the maximum number of times the inliner may inline into a particular routine.

Syntax

Linux OS and macOS:

`-inline-max-per-routine=n`

`-no-inline-max-per-routine`

Windows OS:

`/Qinline-max-per-routine=n`

`/Qinline-max-per-routine-`

Arguments

n	Is a positive integer that specifies the maximum number of times the inliner may inline into a particular routine.

Default

`-no-inline-max-per-routine` or `/Qinline-max-per-routine-`	The compiler uses default heuristics for inline routine expansion.

Description

This option specifies the maximum number of times the inliner may inline into a particular routine. It limits the number of times that inlining can be applied to any routine.

If you specify `-no-inline-max-per-routine` (Linux* and macOS*) or `/Qinline-max-per-routine-` (Windows*), there is no limit to the number of times some routine may be inlined into a particular routine.

To see compiler values for important inlining limits, specify option `[q or Q]opt-report`.

Caution
When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

IDE Equivalent

None

Alternate Options

None

See Also

`inline-factor, Qinline-factor` compiler option

`qopt-report, Qopt-report` compiler option

inline-max-size, Qinline-max-size

Specifies the lower limit for the size of what the inliner considers to be a large routine.

Syntax

Linux OS and macOS:

`-inline-max-size=n`

`-no-inline-max-size`

Windows OS:

`/Qinline-max-size=`*n*

`/Qinline-max-size-`

Arguments

n	Is a positive integer that specifies the minimum size of what the inliner considers to be a large routine.

Default

`-inline-max-size` or `/Qinline-max-size`	The compiler sets the maximum size (*n*) dynamically, based on the platform.

Description

This option specifies the lower limit for the size of what the inliner considers to be a large routine (a function or subroutine). The inliner classifies routines as small, medium, or large. This option specifies the boundary between what the inliner considers to be medium and large-size routines.

The inliner prefers to inline small routines. It has a preference against inlining large routines. So, any large routine is highly unlikely to be inlined.

If you specify `-no-inline-max-size` (Linux* and macOS*) or `/Qinline-max-size-` (Windows*), there are no large routines. Every routine is either a small or medium routine.

To see compiler values for important inlining limits, specify option `[q or Q]opt-report`.

Caution
When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

IDE Equivalent

None

Alternate Options

None

inline-max-total-size, Qinline-max-total-size

Specifies how much larger a routine can normally grow when inline expansion is performed.

Syntax

Linux OS and macOS:

`-inline-max-total-size=`*n*

`-no-inline-max-total-size`

Windows OS:

`/Qinline-max-total-size=n`

`/Qinline-max-total-size-`

Arguments

n	Is a positive integer that specifies the permitted increase in the routine's size when inline expansion is performed.

Default

`-no-inline-max-total-size` or `/Qinline-max-total-size-`	The compiler uses default heuristics for inline routine expansion.

Description

This option specifies how much larger a routine can normally grow when inline expansion is performed. It limits the potential size of the routine. For example, if 2000 is specified for *n*, the size of any routine will normally not increase by more than 2000.

If you specify `-no-inline-max-total-size` (Linux* and macOS*) or `/Qinline-max-total-size-` (Windows*), there is no limit to the size a routine may grow when inline expansion is performed.

To see compiler values for important inlining limits, specify option `[q or Q]opt-report`.

Caution
When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

IDE Equivalent

None

Alternate Options

None

See Also

`inline-factor, Qinline-factor` compiler option

`qopt-report, Qopt-report` compiler option

inline-min-caller-growth, Qinline-min-caller-growth

Lets you specify a procedure size n for which procedures of size <= n do not contribute to the estimated growth of the caller when inlined.

Syntax

Linux OS and macOS:

`-inline-min-caller-growth=n`

Windows OS:

`/Qinline-min-caller-growth=n`

Arguments

n	Is a non-negative integer. When *n* > 0, procedures with a size of *n* are treated as if they are size 0.

Default

`-inline-min-caller-growth=0` or `/Qinline-min-caller-growth=0`	The compiler treats procedures as if they have size zero.

Description

This option lets you specify a procedure size *n* for which procedures of size <= *n* do not contribute to the estimated growth of the caller when inlined. It allows you to inline procedures that the compiler would otherwise consider too large to inline.

NOTE
We recommend that you choose a value of *n* <= 10; otherwise, compile time and code size may greatly increase.

IDE Equivalent

None

Alternate Options

None

inline-min-size, Qinline-min-size

Specifies the upper limit for the size of what the inliner considers to be a small routine.

Syntax

Linux OS and macOS:

`-inline-min-size=`*n*

`-no-inline-min-size`

Windows OS:

`/Qinline-min-size=`*n*

`/Qinline-min-size-`

Arguments

n	Is a positive integer that specifies the maximum size of what the inliner considers to be a small routine.

Default

`-no-inline-min-size` or`/Qinline-min-size-`	The compiler uses default heuristics for inline routine expansion.

Description

This option specifies the upper limit for the size of what the inliner considers to be a small routine (a function or subroutine). The inliner classifies routines as small, medium, or large. This option specifies the boundary between what the inliner considers to be small and medium-size routines.

The inliner has a preference to inline small routines. So, when a routine is smaller than or equal to the specified size, it is very likely to be inlined.

If you specify `-no-inline-min-size` (Linux* and macOS*) or `/Qinline-min-size-` (Windows*), there is no limit to the size of small routines. Every routine is a small routine; there are no medium or large routines.

To see compiler values for important inlining limits, specify option `[q or Q]opt-report`.

> **Caution**
> When you use this option to increase the default limit, the compiler may do so much additional inlining that it runs out of memory and terminates with an "out of memory" message.

IDE Equivalent

None

Alternate Options

None

See Also

`inline-max-size, Qinline-max-size` compiler option

`qopt-report, Qopt-report` compiler option

Qinline-dllimport

Determines whether dllimport functions are inlined.

Syntax

Linux OS:

`None`

macOS:

`None`

Windows OS:

`/Qinline-dllimport`

`/Qinline-dllimport-`

Arguments

None

Default

`/Qinline-dllimport` The dllimport functions are inlined.

Description

This option determines whether dllimport functions are inlined. To disable dllimport functions from being inlined, specify `/Qinline-dllimport-`.

IDE Equivalent

None

Alternate Options

None

Output, Debug, and Precompiled Header (PCH) Options

bintext

Places a text string into the object file (.obj) being generated by the compiler.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/bintext:`*`string`*

`/nobintext`

Arguments

`string`	Is the text string to go into the object file.

Default

`/nobintext`	No text string is placed in the object file.

Description

This option places a text string into the object file (.obj) being generated by the compiler. The string also gets propagated into the executable file.

For example, this option is useful if you want to place a version number or copyright information into the object and executable.

If the string contains a space or tab, the string must be enclosed by double quotation marks ("). A backslash (\) must precede any double quotation marks contained within the string.

If the command line contains multiple `/bintext` options, the last (rightmost) one is used.

IDE Equivalent

Visual Studio: **Code Generation > Object Text String**

Eclipse: None

Xcode: None

Alternate Options

Linux and macOS*: None

Windows: `/V`*string*

c

Prevents linking.

Syntax

Linux OS:

`-c`

macOS:

`-c`

Windows OS:

`/c`

Arguments

None

Default

OFF Linking is performed.

Description

This option prevents linking. Compilation stops after the object file is generated.

The compiler generates an object file for each Fortran source file.

IDE Equivalent

None

Alternate Options

Linux and macOS*: None

Windows: `/compile-only`, `/nolink`

debug (Linux* and macOS*)

Enables or disables generation of debugging information.

Syntax

Linux OS:

`-debug [`*keyword*`]`

macOS:

`-debug [`*keyword*`]`

Windows OS:

`None`

Arguments

keyword

Is the type of debugging information to be generated. Possible values are:

`none`	Disables generation of debugging information.
`full` or `all`	Generates complete debugging information.
`minimal`	Generates line number information for debugging.
`[no]emit_column`	Determines whether the compiler generates column number information for debugging.
`[no]inline-debug-info`	Determines whether the compiler generates enhanced debug information for inlined code.
`[no]pubnames`	Determines whether the compiler generates a DWARF debug_pubnames section.
`[no]semantic-stepping`	Determines whether the compiler generates enhanced debug information useful for breakpoints and stepping.
`[no]variable-locations`	Determines whether the compiler generates enhanced debug information useful in finding scalar local variables.
`extended`	Generates complete debugging information and also sets keyword values `semantic-stepping` and `variable-locations`.
`[no]parallel` (Linux only)	Determines whether the compiler generates parallel debug code instrumentations useful for thread data sharing and reentrant call detection.

For information on the non-default settings for these keywords, see the Description section.

Default

varies

Normally, the default is `-debug none` and no debugging information is generated. However, on Linux*, the `-debug inline-debug-info` option will be enabled by default if you compile with optimizations (option `-O2` or higher) and debugging is enabled (option `-g`).

Description

This option enables or disables generation of debugging information.

By default, enabling debugging, will disable optimization. To enable both debugging and optimization use the `-debug` option together with one of the optimization level options (`-O3`, `-O2` or `-O3`).

Keywords `semantic-stepping`, `inline-debug-info`, `variable-locations`, and `extended` can be used in combination with each other. If conflicting keywords are used in combination, the last one specified on the command line has precedence.

Option	Description
`-debug none`	Disables generation of debugging information.
`-debug full` or `-debug all`	Generates complete debugging information. It is the same as specifying `-debug` with no keyword.
`-debug minimal`	Generates line number information for debugging.
`-debug emit_column`	Generates column number information for debugging.
`-debug inline-debug-info`	Generates enhanced debug information for inlined code. On inlined functions, symbols are (by default) associated with the caller. This option causes symbols for inlined functions to be associated with the source of the called function.
`-debug pubnames`	The compiler generates a DWARF debug_pubnames section. This provides a means to list the names of global objects and functions in a compilation unit.
`-debug semantic-stepping`	Generates enhanced debug information useful for breakpoints and stepping. It tells the debugger to stop only at machine instructions that achieve the final effect of a source statement. For example, in the case of an assignment statement, this might be a store instruction that assigns a value to a program variable; for a function call, it might be the machine instruction that executes the call. Other instructions generated for those source statements are not displayed during stepping. This option has no impact unless optimizations have also been enabled.
`-debug variable-locations`	Generates enhanced debug information useful in finding scalar local variables. It uses a feature of the Dwarf object module known as "location lists". This feature allows the run-time locations of local scalar variables to be specified more accurately; that is, whether, at a given position in the code, a variable value is found in memory or a machine register.
`-debug extended`	Sets keyword values `semantic-stepping` and `variable-locations`. It also tells the compiler to include column numbers in the line information. Generates complete debugging information and also sets keyword values `semantic-stepping` and `variable-locations`. This is a more powerful setting than `-debug full` or `-debug all`.
`-debug parallel`	Generates parallel debug code instrumentations needed for the thread data sharing and reentrant call detection. For this setting to be effective, option `-qopenmp` must be set.

On Linux* systems, debuggers read debug information from executable images. As a result, information is written to object files and then added to the executable by the linker.

On macOS* systems, debuggers read debug information from object files. As a result, the executables don't contain any debug information. Therefore, if you want to be able to debug on these systems, you must retain the object files.

IDE Equivalent

None

Alternate Options

For `-debug full`, `-debug all`, or `-debug`	Linux and macOS*: `-g` Windows: `/debug:full`, `/debug:all`, or `/debug`
For `-debug variable-locations`	Linux and macOS*: `-fvar-tracking` Windows: None
For `-debug semantic-stepping`	Linux and macOS*: `-fvar-tracking-assignments` Windows: None

See Also

`debug` (Windows*) compiler option
`qopenmp, Qopenmp` compiler option

debug (Windows*)

Enables or disables generation of debugging information.

Syntax

Linux OS:

`None`

macOS:

`None`

Windows OS:

`/debug[:keyword]`

`/nodebug`

Arguments

keyword

Is the type of debugging information to be generated. Possible values are:

`none`	Disables generation of debugging information.
`full` or `all`	Generates complete debugging information.
`minimal`	Generates line number information for debugging.
`[no]inline-debug-info`	Determines whether the compiler generates enhanced debug information for inlined code.

For information on the non-default settings for these keywords, see the Description section.

Default

`/debug:none`	This is the default on the command line and for a release configuration in the IDE.
`/debug:all`	This is the default for a debug configuration in the IDE.

Description

This option enables or disables generation of debugging information. It is passed to the linker.

By default, enabling debugging, will disable optimization. To enable both debugging and optimization use the `/debug` option together with one of the optimization level options (`/O3`, `/O2` or `/O3`).

If conflicting keywords are used in combination, the last one specified on the command line has precedence.

Option	Description
`/debug:none`	Disables generation of debugging information. It is the same as specifying /nodebug.
`/debug:full` or `/debug:all`	Generates complete debugging information. It produces symbol table information needed for full symbolic debugging of unoptimized code and global symbol information needed for linking. It is the same as specifying `/debug` with no keyword. If you specify `/debug:full` for an application that makes calls to C library routines and you need to debug calls into the C library, you should also specify `/dbglibs` to request that the appropriate C debug library be linked against.
`/debug:minimal`	Generates line number information for debugging.
`/debug:partial`	Generates global symbol table information needed for linking, but not local symbol table information needed for debugging. This option is deprecated and is not available in the IDE.
`/debug:inline-debug-info`	Generates enhanced debug information for inlined code. On inlined functions, symbols are (by default) associated with the caller. This option causes symbols for inlined functions to be associated with the source of the called function.

IDE Equivalent

Visual Studio: **General > Debug Information Format** (`/debug:minimal`, `/debug:full`)

Eclipse: None

Xcode: None

Alternate Options

For `/debug:all` or `/debug`	Linux and macOS*: None Windows: `/Zi`

See Also

`dbglibs` compiler option

`debug` (Linux* and macOS*) compiler option

debug-parameters

Tells the compiler to generate debug information for PARAMETERs used in a program.

Syntax

Linux OS and macOS:

`-debug-parameters [keyword]`

`-nodebug-parameters`

Windows OS:

`/debug-parameters[:keyword]`

`/nodebug-parameters`

Arguments

keyword Are the PARAMETERs to generate debug information for. Possible values are:

`none`	Generates no debug information for any PARAMETERs used in the program. This is the same as specifying `nodebug-parameters`.
`used`	Generates debug information for only PARAMETERs that have actually been referenced in the program. This is the default if you do not specify a *keyword*.
`all`	Generates debug information for all PARAMETERs defined in the program.

Default

`nodebug-parameters` The compiler generates no debug information for any PARAMETERs used in the program. This is the same as specifying *keyword* `none`.

Description

This option tells the compiler to generate debug information for PARAMETERs used in a program.

Note that if a .mod file contains PARAMETERs, debug information is only generated for the PARAMETERs that have actually been referenced in the program, even if you specify *keyword* `all`.

IDE Equivalent

Visual Studio: **Debugging > Information for PARAMETER Constants**

Eclipse: None

Xcode: **Debug > Information for PARAMETER Constants**

Alternate Options

None

exe

Specifies the name for a built program or dynamic-link library.

Syntax

Linux OS and macOS:

None

Windows OS:

/exe:{*filename* | *dir*}

Arguments

filename Is the name for the built program or dynamic-link library.

dir Is the directory where the built program or dynamic-link library should be placed. It can include *filename*.

Default

OFF The name of the file is the name of the first source file on the command line with file extension .exe, so file.f becomes file.exe.

Description

This option specifies the name for a built program (.EXE) or a dynamic-link library (.DLL).

You can use this option to specify an alternate name for an executable file. This is especially useful when compiling and linking a set of input files. You can use the option to give the resulting file a name other than that of the first input file (source or object) on the command line.

You can use this option to specify an alternate name for an executable file. This is especially useful when compiling and linking a set of input files. You can use the option to give the resulting file a name other than that of the first input file (source or object) on the command line.

IDE Equivalent

None

Alternate Options

Linux and macOS*: -o

Windows: /Fe

Example

The following example creates a dynamic-link library file named file.dll (note that you can use /LD in place of /dll):

```
ifort /dll /exe:file.dll a.f
```

In the following example (which uses the alternate option /Fe), the command produces an executable file named outfile.exe as a result of compiling and linking three files: one object file and two Fortran source files.

```
prompt>ifort /Feoutfile.exe file1.obj file2.for file3.for
```

By default, this command produces an executable file named file1.exe.

- compiler option

Fa

Specifies that an assembly listing file should be generated.

Syntax

Linux OS:

`-Fa[filename|dir]`

macOS:

`-Fa[filename|dir]`

Windows OS:

`/Fa[filename|dir]`

Arguments

filename	Is the name of the assembly listing file.
dir	Is the directory where the file should be placed. It can include *filename*.

Default

OFF	No assembly listing file is produced.

Description

This option specifies that an assembly listing file should be generated (optionally named *filename*).

If *filename* is not specified, the file name will be the name of the source file with an extension of `.asm`; the file is placed in the current directory.

IDE Equivalent

Visual Studio: **Output > ASM Listing Name**

Eclipse: None

Xcode: **Output Files > Filename for Generated Assembler Listing**

Output Files > Generate Assembler Listing

Alternate Options

Linux and macOS*: `-S`

Windows: `/S`, `/asmfile` (this is a deprecated option)

FA

Specifies the contents of an assembly listing file.

Syntax

Linux OS:

`None`

macOS:

`None`

Windows OS:

`/FA[specifier]`

Arguments

specifier	Denotes the contents of the assembly listing file. Possible values are *c*, *s*, or *cs*.

Default

OFF	No source or machine code annotations appear in the assembly listing file, if one is produced.

Description

These options specify what information, in addition to the assembly code, should be generated in the assembly listing file.

To use this option, you must also specify option `/Fa`, which causes an assembly listing to be generated.

Option	Description
`/FA`	Produces an assembly listing without source or machine code annotations.
`/FAc`	Produces an assembly listing with machine code annotations. The assembly listing file shows the hex machine instructions at the beginning of each line of assembly code. The file cannot be assembled; the file name is the name of the source file with an extension of .cod.
`/FAs`	Produces an assembly listing with source code annotations. The assembly listing file shows the source code as interspersed comments. Note that if you use alternate option `-fsource-asm`, you must also specify the `-S` option.
`/FAcs`	Produces an assembly listing with source and machine code annotations. The assembly listing file shows the source code as interspersed comments and shows the hex machine instructions at the beginning of each line of assembly code. This file cannot be assembled.

IDE Equivalent

Visual Studio: **Output Files > Assembler Output**

Eclipse: None

Xcode: None

Alternate Options

`/FAc`	Linux and macOS*: `-fcode-asm` Windows: None
`/FAs`	Linux and macOS*: `-fsource-asm` Windows: None

fcode-asm

Produces an assembly listing with machine code annotations.

Syntax

Linux OS and macOS:

`-fcode-asm`

Windows OS:

`None`

Arguments

None

Default

OFF No machine code annotations appear in the assembly listing file, if one is produced.

Description

This option produces an assembly listing file with machine code annotations.

The assembly listing file shows the hex machine instructions at the beginning of each line of assembly code. The file cannot be assembled; the file name is the name of the source file with an extension of `.cod`.

To use this option, you must also specify option `-S`, which causes an assembly listing to be generated.

IDE Equivalent

None

Alternate Options

Linux and macOS*: None

Windows: `/FAc`

See Also

S compiler option

Fd

Lets you specify a name for a program database (PDB) file created by the compiler.

Syntax

Linux OS:

`None`

macOS:

`None`

Windows OS:

`/Fd[:filename]`

Arguments

filename	Is the name for the PDB file. It can include a path. If you do not specify a file extension, the extension .pdb is used.

Default

OFF	No PDB file is created unless you specify option `/Zi`. If you specify option `/Zi` and `/Fd`, the default filename is vc*x*0.pdb, where *x* represents the version of Visual C++, for example vc100.pdb.

Description

This option lets you specify a name for a program database (PDB) file that is created by the compiler.

A program database (PDB) file holds debugging and project state information that allows incremental linking of a Debug configuration of your program. A PDB file is created when you build with option `/Zi`. Option `/Fd` has no effect unless you specify option `/Zi`.

IDE Equivalent

Visual Studio: **Output Files > Program Database File Name**

Eclipse: None

Xcode: None

Alternate Options

None

See Also

Zi, Z7 compiler option
pdbfile compiler option

feliminate-unused-debug-types, Qeliminate-unused-debug-types

Controls the debug information emitted for types declared in a compilation unit.

Syntax

Linux OS and macOS:

`-feliminate-unused-debug-types`

`-fno-eliminate-unused-debug-types`

Windows OS:

`/Qeliminate-unused-debug-types`

`/Qeliminate-unused-debug-types-`

Arguments

None

Default

`-feliminate-unused-debug-types`	The compiler emits debug information only for types that are actually used by a variable/parameter/etc..

or
`/Qeliminate-unused-debug-types`

Description

This option controls the debug information emitted for types declared in a compilation unit.

If you specify `-fno-eliminate-unused-debug-types` (Linux and macOS*) or `/Qeliminate-unused-debug-types-`, it will cause the compiler to emit debug information for all types present in the sources. This option may cause a large increase in the size of the debug information.

IDE Equivalent

None

Alternate Options

None

fmerge-constants

Determines whether the compiler and linker attempt to merge identical constants (string constants and floating-point constants) across compilation units.

Syntax

Linux OS:

`-fmerge-constants`

`-fno-merge-constants`

macOS:

`None`

Windows OS:

`None`

Arguments

None

Default

`-fmerge-constants`	The compiler and linker attempt to merge identical constants across compilation units if the compiler and linker supports it.

Description

This option determines whether the compiler and linker attempt to merge identical constants (string constants and floating-point constants) across compilation units.

If you do not want the compiler and linker to attempt to merge identical constants across compilation units. specify `-fno-merge-constants`.

IDE Equivalent

None

Alternate Options

None

fmerge-debug-strings

Causes the compiler to pool strings used in debugging information.

Syntax

Linux OS:

`-fmerge-debug-strings`

`-fno-merge-debug-strings`

macOS:

`None`

Windows OS:

`None`

Arguments

None

Default

`-fmerge-debug-strings` The compiler will pool strings used in debugging information.

Description

This option causes the compiler to pool strings used in debugging information. The linker will automatically retain this pooling.

This option can reduce the size of debug information, but it may produce slightly slower compile and link times.

This option is only turned on by default if you are using gcc 4.3 or later, where this setting is also the default, since the generated debug tables require binutils version 2.17 or later to work reliably.

If you do not want the compiler to pool strings used in debugging information, specify option `-fno-merge-debug-strings`.

IDE Equivalent

None

Alternate Options

None

fsource-asm

Produces an assembly listing with source code annotations.

Syntax

Linux OS and macOS:

`-fsource-asm`

Windows OS:

None

Arguments

None

Default

OFF No source code annotations appear in the assembly listing file, if one is produced.

Description

This option produces an assembly listing file with source code annotations. The assembly listing file shows the source code as interspersed comments.

To use this option, you must also specify option `-S`, which causes an assembly listing to be generated.

IDE Equivalent

None

Alternate Options

Linux and macOS*: None

Windows: `/FAs`

See Also

`S` compiler option

ftrapuv, Qtrapuv

Initializes stack local variables to an unusual value to aid error detection.

Syntax

Linux OS:

`-ftrapuv`

macOS:

`-ftrapuv`

Windows OS:

`/Qtrapuv`

Arguments

None

Default

OFF The compiler does not initialize local variables.

Description

This option initializes stack local variables to an unusual value to aid error detection. Normally, these local variables should be initialized in the application. It also unmasks the floating-point invalid exception.

The option sets any uninitialized local variables that are allocated on the stack to a value that is typically interpreted as a very large integer or an invalid address. References to these variables are then likely to cause run-time errors that can help you detect coding errors.

This option sets option `-g` (Linux* and macOS*) and `/Zi` or `/Z7` (Windows*), which changes the default optimization level from `O2` to `-O0` (Linux and macOS*) or `/Od` (Windows). You can override this effect by explicitly specifying an `O` option setting.

This option sets option `[Q]init snan`.

If option `O2` and option `-ftrapuv` (Linux and macOS*) or `/Qtrapuv` (Windows) are used together, you should specify option `-fp-speculation safe` (Linux and macOS*) or `/Qfp-speculation:safe` (Windows) to prevent exceptions resulting from speculated floating-point operations from being trapped.

For more details on using options `-ftrapuv` and `/Qtrapuv` with compiler option `O`, see the article in Intel® Developer Zone titled *Don't optimize when using -ftrapuv for uninitialized variable detection*, which is located in https://software.intel.com/en-us/articles/dont-optimize-when-using-ftrapuv-for-uninitialized-variable-detection/ .

Another way to detect uninitialized local scalar variables is by specifying keyword `uninit` for option `check`.

IDE Equivalent

Visual Studio: **Data > Initialize stack variables to an unusual value**

Eclipse: None

Xcode: **Run-Time > Initialize Stack Variables to an Unusual Value**

Alternate Options

None

See Also

g compiler option
Zi, Z7 compiler option

Locating Run-Time Errors

fverbose-asm

Produces an assembly listing with compiler comments, including options and version information.

Syntax

Linux OS:

```
-fverbose-asm
```

```
-fno-verbose-asm
```

macOS:

```
-fverbose-asm
```

```
-fno-verbose-asm
```

Windows OS:

```
None
```

Arguments

None

Default

`-fno-verbose-asm`	No source code annotations appear in the assembly listing file, if one is produced.

Description

This option produces an assembly listing file with compiler comments, including options and version information.

To use this option, you must also specify `-S`, which sets `-fverbose-asm`.

If you do not want this default when you specify `-S`, specify `-fno-verbose-asm`.

IDE Equivalent

None

Alternate Options

None

See Also

`S` compiler option

g

Tells the compiler to generate a level of debugging information in the object file.

Syntax

Linux OS:

`-g[n]`

macOS:

`-g[n]`

Windows OS:

`See option Zi, Z7.`

Arguments

n	Is the level of debugging information to be generated. Possible values are:
`0`	Disables generation of symbolic debug information.
`1`	Produces minimal debug information for performing stack traces.
`2`	Produces complete debug information. This is the same as specifying `-g` with no *n*.

3	Produces extra information that may be useful for some tools.

Default

-g or -g2	The compiler produces complete debug information.

Description

Option `-g` tells the compiler to generate symbolic debugging information in the object file, which increases the size of the object file.

The compiler does not support the generation of debugging information in assemblable files. If you specify this option, the resulting object file will contain debugging information, but the assemblable file will not.

This option turns off option `-O2` and makes option `-O0` the default unless option `-O2` (or higher) is explicitly specified in the same command line.

Specifying the `-g` or `-O0` option sets the `-fno-omit-frame-pointer` option. On Linux*, the -debug inline-debug-info option will be enabled by default if you compile with optimizations (option `-O2` or higher) and debugging is enabled (option `-g`).

NOTE
When option `-g` is specified, debugging information is generated in the DWARF Version 3 format. Older versions of some analysis tools may require applications to be built with the `-gdwarf-2` option to ensure correct operation.

IDE Equivalent

Visual Studio: None

Eclipse: None

Xcode: **General > Generate Debug Information**

Alternate Options

Linux: None

Windows: /Zi, /Z7

See Also

gdwarf compiler option
Zi, Z7 compiler option
debug (Linux* and macOS*) compiler option

gdwarf

Lets you specify a DWARF Version format when generating debug information.

Syntax

Linux OS:

`-gdwarf-`*n*

macOS:

`-gdwarf-`*n*

Windows OS:

None

Arguments

n	Is a value denoting the DWARF Version format to use. Possible values are:
2	Generates debug information using the DWARF Version 2 format.
3	Generates debug information using the DWARF Version 3 format.
4	Generates debug information using the DWARF Version 4 format. This setting is only available on Linux*.

Default

OFF	No debug information is generated. However, if compiler option `-g` is specified, debugging information is generated in the DWARF Version 3 format.

Description

This option lets you specify a DWARF Version format when generating debug information.

Note that older versions of some analysis tools may require applications to be built with the -gdwarf-2 option to ensure correct operation.

IDE Equivalent

None

Alternate Options

None

See Also

`g` compiler option

grecord-gcc-switches

Causes the command line options that were used to invoke the compiler to be appended to the DW_AT_producer attribute in DWARF debugging information.

Syntax

Linux OS:

```
-grecord-gcc-switches
```

macOS:

None

Windows OS:

None

Arguments

None

Default

OFF	The command line options that were used to invoke the compiler are not appended to the DW_AT_producer attribute in DWARF debugging information.

Description

This option causes the command line options that were used to invoke the compiler to be appended to the DW_AT_producer attribute in DWARF debugging information.

The options are concatenated with whitespace separating them from each other and from the compiler version.

IDE Equivalent

None

Alternate Options

None

gsplit-dwarf

Creates a separate object file containing DWARF debug information.

Syntax

Linux OS:

```
-gsplit-dwarf
```

macOS:

```
None
```

Windows OS:

```
None
```

Arguments

None

Default

OFF	No separate object file containing DWARF debug information is created.

Description

This option creates a separate object file containing DWARF debug information. It causes debug information to be split between the generated object (.o) file and the new DWARF object (.dwo) file.

The DWARF object file is not used by the linker, so this reduces the amount of debug information the linker must process and it results in a smaller executable file.

For this option to perform correctly, you must use binutils-2.24 or later. To debug the resulting executable, you must use gdb-7.6.1 or later.

NOTE
If you use the split executable with a tool that does not support the split DWARF format, it will behave as though the DWARF debug information is absent.

IDE Equivalent

None

Alternate Options

None

list

Tells the compiler to create a listing of the source file.

Syntax

Linux OS and macOS:

`-list[=`*filename*`]`

`-no-list`

Windows OS:

`/list[:`*filename*`]`

`/list-`

Arguments

filename Is the name of the file for output. It can include a path.

Default

`-no-list` No listing is created for the source file.
or `/list-`

Description

This option tells the compiler to create a listing of the source file. The listing contains the following:

- The contents of files included with INCLUDE statements
- A symbol list with a line number cross-reference for each routine
- A list of compiler options used for the current compilation

The contents of the listing can be controlled by specifying option `show`.

The line length of the listing can be specified by using option `list-line-len`.

The page length of the listing can be specified by using option `list-page-len`.

If you do not specify *filename*, the output is written to a file in the same directory as the source. The file name is the name of the source file with an extension of .lst.

IDE Equivalent

Visual Studio: **Output Files > Source Listing** (/list)

Output Files > Source Listing File (/list:[filename])

Eclipse: None

Xcode: **Output Files > Source Listing File**

Output Files > Source Listing File with Cross Reference

Alternate Options

None

See Also

`show` compiler option
`list-line-len` compiler option
`list-page-len` compiler option

list-line-len

Specifies the line length for the listing generated when option list is specified.

Syntax

Linux OS and macOS:

`-list-line-len=`*n*

Windows OS:

`/list-line-len:`*n*

Arguments

n	Is a positive integer indicating the number of columns to show in the listing.

Default

80	When a listing is generated, the default line length is 80 columns.

Description

This option specifies the line length for the listing generated when option `list` is specified.

If you specify option `list-line-len` and do not specify option `list`, the option is ignored.

IDE Equivalent

None

Alternate Options

None

See Also

`list` compiler option
`list-page-len` compiler option

list-page-len

Specifies the page length for the listing generated when option list is specified.

Syntax

Linux OS and macOS:

`-list-page-len=`*n*

Windows OS:

`/list-page-len:`*n*

Arguments

n	Is a positive integer indicating the number of lines on a page to show in the listing.

Default

60	When a listing is generated, the default page length is 60 lines.

Description

This option specifies the page length for the listing generated when option `list` is specified.

If you specify option `list-page-len` and do not specify option `list`, the option is ignored.

IDE Equivalent

None

Alternate Options

None

See Also

`list` compiler option

`list-line-len` compiler option

map-opts, Qmap-opts

Maps one or more compiler options to their equivalent on a different operating system.

Syntax

Linux OS:

`-map-opts`

macOS:

`None`

Windows OS:

`/Qmap-opts`

Arguments

None

Default

OFF	No platform mappings are performed.

Description

This option maps one or more compiler options to their equivalent on a different operating system. The result is output to `stdout`.

On Windows systems, the options you provide are presumed to be Windows options, so the options that are output to `stdout` will be Linux equivalents.

On Linux systems, the options you provide are presumed to be Linux options, so the options that are output to `stdout` will be Windows equivalents.

The tool can be invoked from the compiler command line or it can be used directly.

No compilation is performed when the option mapping tool is used.

This option is useful if you have both compilers and want to convert scripts or makefiles.

NOTE
Compiler options are mapped to their equivalent on the architecture you are using. For example, if you are using a processor with IA-32 architecture, you will only see equivalent options that are available on processors with IA-32 architecture.

IDE Equivalent

None

Alternate Options

None

Example

The following command line invokes the option mapping tool, which maps the Linux options to Windows-based options, and then outputs the results to `stdout`:

```
ifort -map-opts -xP -O2
```

The following command line invokes the option mapping tool, which maps the Windows options to Linux-based options, and then outputs the results to `stdout`:

```
ifort /Qmap-opts /QxP /O2
```

See Also

Compiler Option Mapping Tool

o

Specifies the name for an output file.

Syntax

Linux OS:

`-o filename`

macOS:

`-o filename`

Windows OS:

`None`

Arguments

filename Is the name for the output file. The space before *filename* is optional.

Default

OFF The compiler uses the default file name for an output file.

Description

This option specifies the name for an output file as follows:

- If `-c` is specified, it specifies the name of the generated object file.
- If `-S` is specified, it specifies the name of the generated assembly listing file.
- If -preprocess-only or `-P` is specified, it specifies the name of the generated preprocessor file.

Otherwise, it specifies the name of the executable file.

IDE Equivalent

None

Alternate Options

Linux and macOS*: None

Windows: `/exe`

See Also

`object` compiler option
`exe` compiler option

object

Specifies the name for an object file.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/object:`*`filename`*

Arguments

`filename` Is the name for the object file. It can be a file name or a directory name. A directory name must be followed by a backslash (\). If a special character appears within the file name or directory name, the file name or directory name must appear within quotes. To be safe, you should consider any non-ASCII numeric character to be a special character.

Default

OFF An object file has the same name as the name of the first source file and a file extension of .obj.

Description

This option specifies the name for an object file.

If you specify this option and you omit `/c` or `/compile-only`, the `/object` option gives the object file its name.

On Linux and macOS* systems, this option is equivalent to specifying option `-o`*filename*`-c`.

IDE Equivalent

Visual Studio: **Output Files > Object File Name**

Eclipse: None

Xcode: None

Alternate Options

Linux and macOS*: None

Windows: `/Fo`

Example

The following command shows how to specify a directory:

```
ifort /object:directorya\ end.f
```

If you do not add the backslash following a directory name, an executable is created. For example, the following command causes the compiler to create directorya.exe:

```
ifort /object:directorya end.f
```

The following commands show how to specify a subdirectory that contains a special character:

```
ifort /object:"blank subdirectory"\ end.f
```

```
ifort /object:"c:\my_directory"\ end.f
```

- compiler option

pdbfile

Lets you specify the name for a program database (PDB) file created by the linker.

Syntax

Linux OS:

None

macOS:

None

Windows OS:

`/pdbfile[:`*filename*`]`

Arguments

filename	Is the name for the PDB file. It can include a path. If you do not specify a file extension, the extension .pdb is used.

Default

OFF No PDB file is created unless you specify option `/Zi`. If you specify option `/Zi` the default filename is *executablename*.pdb.

Description

This option lets you specify the name for a program database (PDB) file created by the linker. This option does not affect where the compiler outputs debug information.

To use this option, you must also specify option `/debug:full` or `/Zi`.

If *filename* is not specified, the default file name used is the name of your file with an extension of .pdb.

IDE Equivalent

None

Alternate Options

None

See Also

Zi, Z7 compiler option
`debug` compiler option

print-multi-lib

Prints information about where system libraries should be found.

Syntax

Linux OS:

```
-print-multi-lib
```

macOS:

```
-print-multi-lib
```

Windows OS:

```
None
```

Arguments

None

Default

OFF No information is printed unless the option is specified.

Description

This option prints information about where system libraries should be found, but no compilation occurs. On Linux* systems, it is provided for compatibility with gcc.

IDE Equivalent

None

Alternate Options

None

Quse-msasm-symbols

Tells the compiler to use a dollar sign ("$") when producing symbol names.

Syntax

Linux OS:

`None`

macOS:

`None`

Windows OS:

`/Quse-msasm-symbols`

Arguments

None

Default

OFF	The compiler uses a period (".") when producing symbol names

Description

This option tells the compiler to use a dollar sign ("$") when producing symbol names.

Use this option if you require symbols in your .asm files to contain characters that are accepted by the MS assembler.

IDE Equivalent

None

Alternate Options

None

S

Causes the compiler to compile to an assembly file only and not link.

Syntax

Linux OS:

`-S`

macOS:

`-S`

Windows OS:

`/S`

Arguments

None

Default

OFF Normal compilation and linking occur.

Description

This option causes the compiler to compile to an assembly file only and not link.

On Linux* and macOS* systems, the assembly file name has a .s suffix. On Windows* systems, the assembly file name has an .asm suffix.

IDE Equivalent

None

Alternate Options

Linux and macOS*: None

Windows: `/Fa`

See Also

Fa compiler option

show

Controls the contents of the listing generated when option list is specified.

Syntax

Linux OS and macOS:

`-show` *keyword*`[,` *keyword*`...]`

Windows OS:

`/show:`*keyword*`[,` *keyword*`...]`

Arguments

keyword Specifies the contents for the listing. Possible values are:

`[no]include` Controls whether contents of files added with INCLUDE statements are included when a listing is generated.

`[no]map` Controls whether a symbol listing with a line number cross-reference for each routine is included when a listing is generated.

`[no]options` Controls whether a list of compiler options used for the compilation is included when a listing is generated.

Default

`include`, `map`, and `options` When a listing is generated, it contains the contents of INCLUDEd files, a symbol list with a line number cross reference, and a list of compiler options used.

Description

This option controls the contents of the listing generated when option `list` is specified.

If you specify option `show` and do not specify option `list`, the option is ignored.

IDE Equivalent

None

Alternate Options

None

See Also

`list` compiler option

use-asm, Quse-asm

Tells the compiler to produce objects through the assembler. This is a deprecated option. There is no replacement option.

Syntax

Linux OS and macOS:

`-use-asm`

`-no-use-asm`

Windows OS:

`/Quse-asm`

`/Quse-asm-`

Arguments

None

Default

OFF	The compiler produces objects directly.

Description

This option tells the compiler to produce objects through the assembler.

IDE Equivalent

None

Alternate Options

None

Zi, Z7

Tells the compiler to generate full debugging information in either an object (.obj) file or a project database (PDB) file.

Syntax

Linux OS:

`See option g.`

macOS:

`See option g.`

Windows OS:

`/Zi`

`/Z7`

Arguments

None

Default

OFF No debugging information is produced.

Description

Option `/Z7` tells the compiler to generate symbolic debugging information in the object (.obj) file for use with the debugger. No .pdb file is produced by the compiler.

The `/Zi` option tells the compiler to generate symbolic debugging information in a program database (PDB) file for use with the debugger. Type information is placed in the .pdb file, and not in the .obj file, resulting in smaller object files in comparison to option `/Z7`.

When option `/Zi` is specified, two PDB files are created:

- The compiler creates the program database project.pdb. If you compile a file without a project, the compiler creates a database named vc*x*0.pdb, where *x* represents the major version of Visual C++, for example vc140.pdb.

  This file stores all debugging information for the individual object files and resides in the same directory as the project makefile. If you want to change this name, use option `/Fd`.
- The linker creates the program database executablename.pdb.

  This file stores all debug information for the .exe file and resides in the debug subdirectory. It contains full debug information, including function prototypes, not just the type information found in vc*x*0.pdb.

Both PDB files allow incremental updates. The linker also embeds the path to the .pdb file in the .exe or .dll file that it creates.

The compiler does not support the generation of debugging information in assemblable files. If you specify these options, the resulting object file will contain debugging information, but the assemblable file will not.

These options turn off option `/O2` and make option `/Od` the default unless option `/O2` (or higher) is explicitly specified in the same command line.

For more information about the `/Z7` and `/Zi` options, see the Microsoft documentation.

IDE Equivalent

Visual Studio: **General > Generate Debug Information**

Eclipse: None

Xcode: None

Alternate Options

Linux: -g

Windows: None

See Also

Fd compiler option
g compiler option
debug (Windows*) compiler option

Zo

Enables or disables generation of enhanced debugging information for optimized code.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/Zo`

`/Zo-`

Arguments

None

Default

OFF The compiler does not generate enhanced debugging information for optimized code.

Description

This option enables or disables the generation of additional debugging information for local variables and inlined routines when code optimizations are enabled. It should be used with option `/Zi` or `/Z7` to allow improved debugging of optimized code.

Option `/Zo` enables generation of this enhanced debugging information. Option `/Zo-` disables this functionality.

For more information on code optimization, see option `/O`.

IDE Equivalent

None

Alternate Options

None

See Also

Zi, Z7 compiler option
debug (Windows*) compiler option
O compiler option

Preprocessor Options

B

Specifies a directory that can be used to find include files, libraries, and executables.

Syntax

Linux OS:

`-B`*dir*

macOS:

`-B`*dir*

Windows OS:

`None`

Arguments

dir	Is the directory to be used. If necessary, the compiler adds a directory separator character at the end of *dir*.

Default

OFF	The compiler looks for files in the directories specified in your PATH environment variable.

Description

This option specifies a directory that can be used to find include files, libraries, and executables.

The compiler uses *dir* as a prefix.

For include files, the *dir* is converted to `-I`/*dir*/include. This command is added to the front of the includes passed to the preprocessor.

For libraries, the *dir* is converted to `-L`/*dir*. This command is added to the front of the standard `-L` inclusions before system libraries are added.

For executables, if *dir* contains the name of a tool, such as `ld` or `as`, the compiler will use it instead of those found in the default directories.

The compiler looks for include files in *dir* /include while library files are looked for in *dir*.

IDE Equivalent

None

Alternate Options

None

D

Defines a symbol name that can be associated with an optional value.

Syntax

Linux OS:

`-Dname[=value]`

macOS:

`-Dname[=value]`

Windows OS:

`/Dname[=value]`

Arguments

name	Is the name of the symbol.
value	Is an optional integer or an optional character string delimited by double quotes; for example, `D`*name=string*.

Default

`noD` Only default symbols or macros are defined.

Description

Defines a symbol name that can be associated with an optional value. This definition is used during preprocessing in both Intel® Fortran conditional compilation directives and the fpp preprocessor. The D*name=value* will be ignored if there are any non-alphabetic, non-numeric characters in *name*.

If a *value* is not specified, *name* is defined as "1".

If you want to specify more than one definition, you must use separate `D` options.

If you specify `noD`, all preprocessor definitions apply only to fpp and not to Intel® Fortran conditional compilation directives. To use this option, you must also specify the `fpp` option.

Caution
On Linux* and macOS* systems, if you are not specifying a *value*, do not use `D` for *name*, because it will conflict with the `-DD` option.

IDE Equivalent

Visual Studio: **General > Preprocessor Definitions**

Preprocessor> Preprocessor Definitions

Preprocessor > Preprocessor Definitions to FPP only

Eclipse: None

Xcode: **Preprocessor > Preprocessor Definitions**

Preprocessor > Preprocessor Definitions to FPP only

Alternate Options

D	Linux and macOS*: None Windows: `/define:`*name[=value]*
noD	Linux and macOS*: `-nodefine`

Windows: `/nodefine`

See Also

Using Predefined Preprocessor Symbols

d-lines, Qd-lines

Compiles debug statements.

Syntax

Linux OS and macOS:

`-d-lines`

`-nod-lines`

Windows OS:

`/d-lines`

`/nod-lines`

`/Qd-lines`

Arguments

None

Default

`nod-lines` Debug lines are treated as comment lines.

Description

This option compiles debug statements. It specifies that lines in fixed-format files that contain a D in column 1 (debug statements) should be treated as source code.

IDE Equivalent

Visual Studio: **Language > Compile Lines With D in Column 1** (/d-lines)

Eclipse: None

Xcode: **Language > Compile Lines With D in Column 1**

Alternate Options

Linux and macOS*: `-DD`

Windows: None

E

Causes the preprocessor to send output to stdout.

Syntax

Linux OS:

`-E`

macOS:

`-E`

Windows OS:

`/E`

Arguments

None

Default

OFF Preprocessed source files are output to the compiler.

Description

This option causes the preprocessor to send output to `stdout`. Compilation stops when the files have been preprocessed.

When you specify this option, the compiler's preprocessor expands your source module and writes the result to `stdout`. The preprocessed source contains #line directives, which the compiler uses to determine the source file and line number.

IDE Equivalent

None

None

Alternate Options

None

EP

Causes the preprocessor to send output to stdout, omitting #line directives.

Syntax

Linux OS:

`-EP`

macOS:

`-EP`

Windows OS:

`/EP`

Arguments

None

Default

OFF Preprocessed source files are output to the compiler.

Description

This option causes the preprocessor to send output to `stdout`, omitting #line directives.

If you also specify option `preprocess-only`, option `P`, or option `F`, the preprocessor will write the results (without #line directives) to a file instead of `stdout`.

IDE Equivalent

None

Alternate Options

None

fpp

Runs the Fortran preprocessor on source files before compilation.

Syntax

Linux OS and macOS:

`-fpp`

`-nofpp`

Windows OS:

`/fpp`

`/fpp[:"`*`fpp_option`*`"]`

`/nofpp`

Arguments

fpp_option	Is a Fortran preprocessor (fpp) option; it must start with a slash (/) and appear in quotes. This argument is only allowed on Windows* systems.

Default

`nofpp`	The Fortran preprocessor is not run on files before compilation.

Description

This option runs the Fortran preprocessor on source files before they are compiled.

If you want to pass fpp options to the Fortran preprocessor, you can use any of the following methods:

- Use option `Qoption,fpp,"option"`. This is the recommended method.
- On Windows* systems, use this option (`fpp`) and include the argument *fpp_option* (for example, `fpp:"/macro=no"`).
- On Linux* and macOS* systems, use option `-Wp,fpp_option` (for example, `-Wp,-macro=no`).

To see a list of all available fpp options, specify one of the following on the command line:

```
fpp -help    ! Linux and macOS* systems
```

```
fpp /help    ! Windows systems
```

IDE Equivalent

Visual Studio: **Preprocessor > Preprocess Source File**

Eclipse: None

Xcode: **Preprocessor > Preprocess Source File**

Alternate Options

Linux and macOS*: `-cpp` (this is a deprecated option)

Windows: None

Example

The following examples show the recommended method of passing fpp options to the Fortran preprocessor:

```
ifort /fpp /Qoption,fpp,"/macro=no_com"  file.f90        ! Disables macro expansion within
comments (Windows*)
```

```
ifort -fpp -Qoption,fpp,"-undef"  file.f90               ! Undefines all predefined macros
(Linux* and macOS*)
```

Qoption
compiler option

Using Fortran Preprocessor Options

Wp
compiler option

fpp-name

Lets you specify an alternate preprocessor to use with Fortran.

Syntax

Linux OS and macOS:

`-fpp-name=`*name*

Windows OS:

`/fpp-name:`*name*

Arguments

name	Is the name of the preprocessor executable. It can include a path. See the description below for more details.

Default

OFF	No preprocessor is run on files before compilation.

Description

This option lets you specify an alternate preprocessor to use with Fortran.

The compiler invokes the user-specified Fortran preprocessor by spawning a command with the following signature:

```
alt_fpp [ [-D<define>]..] [[-I<include directory>]..] inputfile
```

where `alt_fpp` is the name of the Fortran preprocessor you want to use. Output from the preprocessor goes to STDOUT and will be captured for any further processing.

You can use option `Qoption,fpp,…` to pass options, other than the definitions (`-D` xxx) or include directories (`-I` xxx), to the preprocessor.

You can use option `Qlocation, fpp,…` to specify a directory for supporting tools.

IDE Equivalent

None

Alternate Options

None

See Also

fpp Preprocessing
`fpp` compiler option
`Qoption` compiler option
`Qlocation` compiler option

gen-dep

Tells the compiler to generate build dependencies for the current compilation.

Syntax

Linux OS and macOS:

`-gen-dep[=filename]`

`-no-gen-dep`

Windows OS:

`/gen-dep[:filename]`

`/gen-dep-`

Arguments

filename Is the name of the file for output. It can include a path.

If you specify *filename*, it is similar to specifying option [Q]MF*filename*. If you do not specify *filename*, it is similar to specifying option [Q]MD or [Q]MMD.

Default

`-no-gen-dep` The compiler does not generate build dependencies for the compilation.

or
`/gen-dep-`

Description

This option tells the compiler to generate build dependencies for the current compilation. The build dependencies include a list of all files included with INCLUDE statements or .mod files accessed with USE statements.

If you do not specify *filename*, the dependencies are written to stdout.

You can use option `gen-depformat` to specify the form of the output for the build dependencies generated.

If you specify option `gen-dep` and you do not specify option `gen-depformat`, the output format is in a form acceptable to the make utility.

Note that if option `fpp` is used to process #include files, those files will also appear in the list of build dependencies.

If you want to generate build dependencies but you do not want to compile the sources, you must also specify option `syntax-only`.

IDE Equivalent

Visual Studio: **Output Files > Build Dependencies** (/gen-dep)

Output Files > Emit Build Dependencies to File (/gen-dep:filename)

Output Files > Build Dependencies File (/gen-dep:filename)

Eclipse: None

Xcode: **Output Files > Create a List of Build Dependencies** (-gen-dep)

Output Files > Build Dependencies File (/gen-dep:filename)

Alternate Options

`gen-dep` with a *filename*	Linux and macOS*: `-MF` Windows: `/QMF`
`gen-dep` with no *filename*	Linux and macOS*: `-MD` or `-MMD` Windows: `/QMD` or `/QMMD`

See Also

`gen-depformat` compiler option

`gen-depshow` compiler option

`syntax-only` compiler option

gen-depformat

Specifies the form for the output generated when option gen-dep is specified.

Syntax

Linux OS and macOS:

`-gen-depformat=`*`form`*

Windows OS:

`/gen-depformat:`*`form`*

Arguments

form	Is the output form for the list of build dependencies. Possible values are make or nmake.

Default

make	The output form for the list of build dependencies is in a form acceptable to the make utility.

Description

This option specifies the form for the output generated when option `gen-dep` is specified.

If you specify option `gen-depformat` and do not specify option `gen-dep`, the option is ignored.

IDE Equivalent

None

Alternate Options

None

See Also

`gen-dep` compiler option

gen-depshow

Determines whether certain features are excluded from dependency analysis. Currently, it only applies to intrinsic modules.

Syntax

Linux OS and macOS:

`-gen-depshow=`*`keyword`*

Windows OS:

`/gen-depshow:`*`keyword`*

Arguments

`keyword` Specifies inclusion or exclusion from dependency analysis. Possible values are:

`[no]intr_mod` Determines whether intrinsic modules are excluded from dependency analysis.

Default

`nointr_mod` Tells the compiler to exclude Fortran intrinsic modules in dependency analysis.

Description

This option determines whether certain features are excluded from dependency analysis. Currently, it only applies to intrinsic modules.

Option	Description
`gen-depshow intr_mod`	Tells the compiler to include Fortran intrinsic modules in dependency analysis.

If you do not specify option `gen-dep`, the compiler does not generate build dependencies for the compilation.

If you specify option `gen-depshow` and do not specify option `gen-dep`, the option is ignored.

IDE Equivalent

None

Alternate Options

`gen-depshow nointr_mod` Linux and macOS*: `-MMD`

Windows: `/QMMD`

`gen-dep` compiler option

I

Specifies an additional directory for the include path.

Syntax

Linux OS and macOS:

`-I`*dir*

Windows OS:

`/I`*dir*

Arguments

dir	Is the directory to add to the include path.

Default

OFF	The default include path is used.

Description

This option specifies an additional directory for the include path, which is searched for module files referenced in USE statements and include files referenced in INCLUDE statements. To specify multiple directories on the command line, repeat the option for each directory you want to add.

For all USE statements and for those INCLUDE statements whose file name does not begin with a device or directory name, the directories are searched in this order:

1. The directory containing the first source file.

   Note that if `assume nosource_include` is specified, this directory will not be searched.
2. The current working directory where the compilation is taking place (if different from the above directory).
3. Any directory or directories specified using the I option. If multiple directories are specified, they are searched in the order specified on the command line, from left to right.
4. On Linux* and macOS* systems, any directories indicated using environment variable CPATH. On Windows* systems, any directories indicated using environment variable INCLUDE.

This option affects fpp preprocessor behavior and the USE statement.

IDE Equivalent

Visual Studio: **General > Additional Include Directories** (/I)

Preprocessor > Additional Include Directories (/I)

Eclipse: None

Xcode: **Preprocessor > Additional Include Directories** (/I)

Alternate Options

Linux and macOS*: None

Windows: `/include`

See Also

`X` compiler option

`assume` compiler option

idirafter

Adds a directory to the second include file search path.

Syntax

Linux OS:

`-idirafter`*dir*

macOS:

`-idirafter`*dir*

Windows OS:

`None`

Arguments

dir	Is the name of the directory to add.

Default

OFF	Include file search paths include certain default directories.

Description

This option adds a directory to the second include file search path (after `-I`).

IDE Equivalent

None

Alternate Options

None

isystem

Specifies a directory to add to the start of the system include path.

Syntax

Linux OS:

`-isystem`*dir*

macOS:

`-isystem`*dir*

Windows OS:

`None`

Arguments

dir	Is the directory to add to the system include path.

Default

OFF The default system include path is used.

Description

This option specifies a directory to add to the system include path. The compiler searches the specified directory for include files after it searches all directories specified by the `-I` compiler option but before it searches the standard system directories.

On Linux* systems, this option is provided for compatibility with gcc.

IDE Equivalent

None

Alternate Options

None

module

Specifies the directory where module files should be placed when created and where they should be searched for.

Syntax

Linux OS and macOS:

`-module` *path*

Windows OS:

`/module:`*path*

Arguments

path Is the directory for module files.

Default

OFF The compiler places module files in the current directory.

Description

This option specifies the directory (path) where module (.mod) files should be placed when created and where they should be searched for (USE statement).

IDE Equivalent

Visual Studio: **Output > Module Path**

Eclipse: None

Xcode: **Output Files > Module Path**

Alternate Options

None

preprocess-only

Causes the Fortran preprocessor to send output to a file.

Syntax

Linux OS and macOS:

`-preprocess-only`

Windows OS:

`/preprocess-only`

Arguments

None

Default

OFF Preprocessed source files are output to the compiler.

Description

This option causes the Fortran preprocessor to send output to a file.

The source file is preprocessed by the Fortran preprocessor, and the result for each source file is output to a corresponding .i or .i90 file.

Note that the source file is not compiled.

IDE Equivalent

None

Alternate Options

Linux and macOS*: `-P`

Windows: `/P`

u (Windows*)

Undefines all previously defined preprocessor values.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/u`

Arguments

None

Default

OFF Defined preprocessor values are in effect until they are undefined.

Description

This option undefines all previously defined preprocessor values.

To undefine specific preprocessor values, use the `/U` option.

IDE Equivalent

Visual Studio: **Preprocessor > Undefine All Preprocessor Definitions**

Eclipse: None

Xcode: None

Alternate Options

None

See Also

`U` compiler option

U

Undefines any definition currently in effect for the specified symbol.

Syntax

Linux OS:

`-U`*name*

macOS:

`-U`*name*

Windows OS:

`/U`*name*

Arguments

name	Is the name of the symbol to be undefined.

Default

OFF	Symbol definitions are in effect until they are undefined.

Description

This option undefines any definition currently in effect for the specified symbol.

On Windows systems, use the `/u` option to undefine all previously defined preprocessor values.

IDE Equivalent

Visual Studio: **Preprocessor > Undefine Preprocessor Definitions**

Eclipse: None

Xcode: **Preprocessor > Undefine Preprocessor Definitions**

Alternate Options

Linux and macOS*: None

Windows: `/undefine:`*name*

undef

Disables all predefined symbols.

Syntax

Linux OS:

`-undef`

macOS:

`-undef`

Windows OS:

`None`

Arguments

None

Default

OFF Defined symbols are in effect until they are undefined.

Description

This option disables all predefined symbols.

IDE Equivalent

None

Alternate Options

None

X

Removes standard directories from the include file search path.

Syntax

Linux OS:

`-X`

macOS:

`-X`

Windows OS:

`/X`

Arguments

None

Default

OFF Standard directories are in the include file search path.

Description

This option removes standard directories from the include file search path. It prevents the compiler from searching the default path specified by the CPATH environment variable.

On Linux* and macOS* systems, specifying `-X` (or `-noinclude`) prevents the compiler from searching in `/usr/include` for files specified in an INCLUDE statement.

You can use this option with the `I` option to prevent the compiler from searching the default path for include files and direct it to use an alternate path.

This option affects fpp preprocessor behavior and the USE statement.

IDE Equivalent

Visual Studio: **Preprocessor > Ignore Standard Include Path** (/X)

Eclipse: None

Xcode: **Preprocessor > Ignore Standard Include Path** (-X)

Alternate Options

Linux and macOS*: `-nostdinc`

Windows: /noinclude

See Also

`I` compiler option

Component Control Options

Qinstall

Specifies the root directory where the compiler installation was performed.

Syntax

Linux OS:

`-Qinstall`*`dir`*

macOS:

`-Qinstall`*`dir`*

Windows OS:

`None`

Arguments

dir Is the root directory where the installation was performed.

Default

OFF The default root directory for compiler installation is searched for the compiler.

Description

This option specifies the root directory where the compiler installation was performed. It is useful if you want to use a different compiler or if you did not use the compilervars shell script to set your environment variables.

IDE Equivalent

None

Alternate Options

None

Qlocation

Specifies the directory for supporting tools.

Syntax

Linux OS:

`-Qlocation,`*`string`*`,`*`dir`*

macOS:

`-Qlocation,`*`string`*`,`*`dir`*

Windows OS:

`/Qlocation,`*`string`*`,`*`dir`*

Arguments

string	Is the name of the tool.
dir	Is the directory (path) where the tool is located.

Default

OFF	The compiler looks for tools in a default area.

Description

This option specifies the directory for supporting tools.

string can be any of the following:

- f - Indicates the Intel® Fortran compiler.
- fpp (or cpp) - Indicates the Intel® Fortran preprocessor or a user-specified (alternate) Fortran preprocessor.
- asm - Indicates the assembler.
- link - Indicates the linker.
- prof - Indicates the profiler.
- On Windows* systems, the following is also available:
  - masm - Indicates the Microsoft assembler.
- On Linux* and macOS* systems, the following are also available:
  - as - Indicates the assembler.
  - gas - Indicates the GNU assembler. This setting is for Linux* only.
  - ld - Indicates the loader.
  - gld - Indicates the GNU loader. This setting is for Linux* only.

- lib - Indicates an additional library.
- crt - Indicates the crt%.o files linked into executables to contain the place to start execution.

On Windows and macOS* systems, you can also specify a tool command name.

The following shows an example on macOS* systems:

```
-Qlocation,ld,/usr/bin               ! This tells the driver to use /usr/bin/ld for the loader
-Qlocation,ld,/usr/bin/gld           ! This tells the driver to use /usr/bin/gld as the loader
```

The following shows an example on Windows* systems:

```
/Qlocation,link,"c:\Program Files\tools\"            ! This tells the driver to use c:\Program
Files\tools\link.exe for the loader
/Qlocation,link,"c:\Program Files\tools\my_link.exe" ! This tells the driver to use c:\Program
Files\tools\my_link.exe as the loader
```

IDE Equivalent

None

Alternate Options

None

Example

The following command provides the path for the fpp tool:

```
ifort -Qlocation,fpp,/usr/preproc myprog.f
```

See Also

`Qoption` compiler option

Qoption

Passes options to a specified tool.

Syntax

Linux OS:

`-Qoption,`*`string`*`,`*`options`*

macOS:

`-Qoption,`*`string`*`,`*`options`*

Windows OS:

`/Qoption,`*`string`*`,`*`options`*

Arguments

string	Is the name of the tool.
options	Are one or more comma-separated, valid options for the designated tool. Note that certain tools may require that options appear within quotation marks (" ").

Default

OFF No options are passed to tools.

Description

This option passes options to a specified tool.

If an argument contains a space or tab character, you must enclose the entire argument in quotation marks (" "). You must separate multiple arguments with commas.

string can be any of the following:

- fpp (or cpp) - Indicates the Intel® Fortran preprocessor or a user-specified (alternate) Fortran preprocessor.
- asm - Indicates the assembler.
- link - Indicates the linker.
- prof - Indicates the profiler.
- On Windows* systems, the following is also available:
  - masm - Indicates the Microsoft assembler.
- On Linux* and macOS* systems, the following are also available:
  - as - Indicates the assembler.
  - gas - Indicates the GNU assembler.
  - ld - Indicates the loader.
  - gld - Indicates the GNU loader.
  - lib - Indicates an additional library.
  - crt - Indicates the crt%.o files linked into executables to contain the place to start execution.

IDE Equivalent

None

Alternate Options

None

Example

Examples for Linux* and macOS* systems:

The following example directs the linker to link with an alternative library:

```
ifort -Qoption,link,-L.,-Lmylib prog1.f
```

The following example passes a compiler option to the assembler to generate a listing file:

```
ifort -Qoption,as,"-as=myprogram.lst" -use-asm myprogram.f90
```

The following option passes an `fpp` option to the Fortran preprocessor:

```
ifort -Qoption,fpp,"-fpp=macro=no
```

Examples for Windows* systems:

The following example directs the linker to create a memory map when the compiler produces the executable file from the source being compiled:

```
ifort /Qoption,link,/map:prog1.map prog1.f
```

The following example passes a compiler option to the assembler:

```
ifort /Quse-asm /Qoption,masm,"/WX" myprogram.f90
```

The following option passes an `fpp` option to the Fortran preprocessor:

```
ifort /Qoption,fpp,"/fpp:macro=no"
```

See Also

`Qlocation` compiler option

Language Options

allow

Determines whether the compiler allows certain behaviors.

Syntax

Linux OS and macOS:

`-allow` *keyword*

Windows OS:

`/allow:`*keyword*

Arguments

keyword Specifies the behaviors to allow or disallow. Possible values are:

`[no]fpp_comments` Determines how the fpp preprocessor treats Fortran end-of-line comments in preprocessor directive lines.

Default

`fpp_comments` The compiler recognizes Fortran-style end-of-line comments in preprocessor lines.

Description

This option determines whether the compiler allows certain behaviors.

Option	Description
`allow nofpp_comments`	Tells the compiler to disallow Fortran-style end-of-line comments on preprocessor lines. Comment indicators have no special meaning.

IDE Equivalent

None

Alternate Options

None

Example

Consider the following:

```
#define MAX_ELEMENTS 100  ! Maximum number of elements
```

By default, the compiler recognizes Fortran-style end-of-line comments on preprocessor lines. Therefore, the line above defines MAX_ELEMENTS to be "100" and the rest of the line is ignored. If `allow nofpp_comments` is specified, Fortran comment conventions are not used and the comment indicator "!" has no special meaning. So, in the above example, "! Maximum number of elements" is interpreted as part of the value for the MAX_ELEMENTS definition.

Option `allow nofpp_comments` can be useful when you want to have a Fortran directive as a define value; for example:

```
#define dline(routname) !dir$ attributes alias:"__routname":: routname
```

altparam

Allows alternate syntax (without parentheses) for PARAMETER statements.

Syntax

Linux OS and macOS:

`-altparam`

`-noaltparam`

Windows OS:

`/altparam`

`/noaltparam`

Arguments

None

Default

`altparam` The alternate syntax for PARAMETER statements is allowed.

Description

This option specifies that the alternate syntax for PARAMETER statements is allowed. The alternate syntax is:

```
PARAMETER c = expr [, c = expr] ...
```

This statement assigns a name to a constant (as does the standard PARAMETER statement), but there are no parentheses surrounding the assignment list.

In this alternative statement, the form of the constant, rather than implicit or explicit typing of the name, determines the data type of the variable.

IDE Equivalent

Visual Studio: **Language > Enable Alternate PARAMETER Syntax**

Eclipse: None

Xcode: **Language > Enable Alternate PARAMETER Syntax**

Alternate Options

`altparam` Linux and macOS*: None

Windows: `/4Yaltparam`

`noaltparam` Linux and macOS*: None

Windows: `/4Naltparam`

assume

Tells the compiler to make certain assumptions.

Syntax

Linux OS and macOS:

`-assume` *keyword*`[,` *keyword*`...]`

Windows OS:

`/assume:`*keyword*`[,` *keyword*`...]`

Arguments

keyword Specifies the assumptions to be made. Possible values are:

`none`	Disables all assume options.
`[no]bscc`	Determines whether the backslash character is treated as a C-style control character syntax in character literals.
`[no]buffered_io`	Determines whether data is immediately read from or written to disk or accumulated in a buffer. For variable length, unformatted files, determines whether data is buffered on input or read directly from disk to user variables.
`[no]buffered_stdout`	Determines whether data is immediately written to the standard output device or accumulated in a buffer.
`[no]byterecl`	Determines whether units for the OPEN statement RECL specifier (record length) value in unformatted files are in bytes or longwords (four-byte units).
`[no]cc_omp`	Determines whether conditional compilation as defined by the OpenMP Fortran API is enabled or disabled.
`[no]contiguous_assumed_shape`	Determines whether contiguity is assumed for assumed-shape dummy arguments.
`[no]contiguous_pointer`	Determines whether contiguity is assumed for pointers.
`[no]dummy_aliases`	Determines whether the compiler assumes that dummy arguments to procedures share memory locations with other dummy arguments or with COMMON variables that are assigned.
`[no]fpe_summary`	Determines whether a floating-point exceptions summary is displayed when a STOP or ERROR STOP statement is encountered.

`[no]ieee_fpe_flags`	Determines whether the floating-point exception and status flags are saved on routine entry and restored on routine exit.
`[no]minus0`	Determines whether the compiler uses Fortran 2003 or Fortran 90/77 standard semantics in the SIGN intrinsic when treating -0.0 and +0.0 as 0.0, and how it writes the value on formatted output.
`[no]old_boz`	Determines whether the binary, octal, and hexadecimal constant arguments in intrinsic functions INT, REAL, DBLE, and CMPLX are treated as signed integer constants.
`[no]old_inquire_recl`	Determines the value of the RECL= specifier on an INQUIRE statement for an unconnected unit or a unit connected for stream access. Prior to Fortran 2018, this behavior was undefined (`ifort` used the value 0 for an unconnected file). Fortran 2018 specifies that the *scalar-int-variable* in the RECL= specifier becomes defined with -1 if the file is unconnected, and -2 if the file is connected for stream access.
`[no]old_ldout_format`	Determines the output of integer and real values in list-directed and namelist-directed output.
`[no]old_ldout_zero`	Determines the format of a floating-point zero produced by list-directed output. `old_ldout_zero` uses exponential format; `noold_ldout_zero` uses fractional format.
`[no]old_logical_assign`	Determines the behavior in assignment statements of logical values assigned to numeric variables and numeric values assigned to logical variables.
`[no]old_logical_ldio`	Determines whether NAMELIST and list-directed input accept logical values for numeric IO-list items and numeric values for logical IO-list items.
`[no]old_maxminloc`	Determines the results of intrinsics MAXLOC and MINLOC when given an empty array as an argument or every element of the mask is false.
`[no]old_unit_star`	Determines whether unit * is treated the same as units 5 and 6, or is distinct.
`[no]old_xor`	Determines whether .XOR. is defined by the compiler as an intrinsic operator.
`[no]protect_allocates`	Determines whether memory allocation requests using the ALLOCATE statement are protected with critical sections to avoid random timing problems in a multi-threaded environment.
`[no]protect_constants`	Determines whether a constant actual argument or a copy of it is passed to a called routine.
`[no]protect_parens`	Determines whether the optimizer honors parentheses in REAL and COMPLEX expression evaluations by not reassociating operations.

[no]realloc_lhs	Determines whether the compiler uses the current Fortran Standard rules or the old Fortran 2003 rules when interpreting assignment statements.
[no]recursion	Determines whether procedures are compiled for recursion by default.
[no]source_include	Determines whether the compiler searches for USE modules and INCLUDE files in the default directory or in the directory where the source file is located.
[no]std_intent_in	Determines whether the compiler assumes that dummy arguments with the INTENT(IN) attribute in a called procedure are not modified across a call, in accordance with the Fortran standard.
[no]std_minus0_rounding	Determines whether to display a negative value that is not zero but rounds to zero on output with a leading minus sign.
[no]std_mod_proc_name	Determines whether the names of module procedures are allowed to conflict with user external symbol names.
[no]std_value	Determines whether the VALUE attribute has the effect as if the actual argument is assigned to a temporary, and the temporary is then passed to the called procedure so that subsequent changes to the value of the dummy argument do not affect the actual argument, in accordance with the Fortran standard.
[no]underscore	Determines whether the compiler appends an underscore character to external user-defined names.
[no]2underscores (Linux and macOS*)	Determines whether the compiler appends two underscore characters to external user-defined names.
[no]writeable-strings	Determines whether character constants go into non-read-only memory.

Default

nobscc	The backslash character is treated as a normal character in character literals.
nobuffered_io	Data in the internal buffer is immediately read from or written (flushed) to disk (OPEN specifier BUFFERED='NO'). Data read from variable length, unformatted files is read directly from disk to a user's variables. If you set the FORT_BUFFERED environment variable to true, the default is `assume buffered_io`.

`nobuffered_stdout` Data is not buffered for the standard output device but instead is written immediately to the device.

`nobyterecl` Units for OPEN statement RECL values with unformatted files are in four-byte (longword) units.

`nocc_omp` Conditional compilation as defined by the OpenMP Fortran API is disabled unless option `[q or Q]openmp` is specified.

If compiler option `[q or Q]openmp` is specified, the default is `assume cc_omp`.

`nocontiguous_assumed_shape` Contiguity is not assumed for assumed-shape dummy arguments.

`nocontiguous_pointer` Contiguity is not assumed for pointers.

`nodummy_aliases` Dummy arguments to procedures do not share memory locations with other dummy arguments or with variables shared through use association, host association, or common block use.

`nofpe_summary` Suppresses a summary of floating-point exceptions from being displayed when a STOP or ERROR STOP statement is encountered.

`noieee_fpe_flags` The flags are not saved on routine entry and they are not restored on routine exit.

`nominus0` The compiler uses Fortran 90/77 standard semantics in the SIGN intrinsic to treat -0.0 and +0.0 as 0.0, and writes a value of 0.0 with no sign on formatted output.

`noold_boz` The binary, octal, and hexadecimal constant arguments in intrinsic functions INT, REAL, DBLE, and CMPLX are treated as bit strings that represent a value of the data type of the intrinsic, that is, the bits are not converted.

`old_inquire_recl` The *scalar-int-variable* in a RECL= specifier of an INQUIRE statement for an unconnected unit becomes defined with the value 0; if the unit is connected for stream access, the value is undefined.

`old_ldout_format` For list-directed and namelist-directed output, integers are written with a fixed width that is dependent on the integer kind, and zero real values are written using the E format.

`old_ldout_zero` For list-directed output of a floating-point zero, exponential format is used instead of fractional output.

`noold_logical_assign` In the assignment statement L = N, where L is a logical variable and N is a numeric value, N is converted to integer if necessary, and L is assigned the value .FALSE. if the integer value is 0, and .TRUE. if the integer value is -1 or 1 according to the setting of the compiler option `fpscomp logicals`.

In the assignment statement N = L, where N is a variable of numeric type and L is a logical value, if L is .FALSE., N is assigned the value 0, converted, if necessary, to the type of N. If L is .TRUE., N is assigned the value 1 or -1, converted, if necessary, to the type of N, according to the setting of the compiler option `fpscomp logicals`.

The compiler option `fpscomp logicals` specifies that non-zero values are treated as true and zero values are treated as false. The literal constant .TRUE. has an integer value of 1 and the literal constant .FALSE. has an integer value of 0.

The default is `fpscomp nologicals`, which specifies that odd integer values (low bit one) are treated as true and even integer values (low bit zero) are treated as false. The literal constant .TRUE. has an integer value of -1 and the literal constant .FALSE. has an integer value of 0.

`noold_logical_ldio` Tells the compiler that NAMELIST and list-directed input cannot accept logical values (T, F, etc.) for numeric (integer, real, and complex) IO-list items or numeric values for logical IO-list items. If this option is specified and a logical value is given for a numeric item or a numeric value is given for a logical item in NAMELIST and list-directed input, a run-time error will be produced.

`old_maxminloc` MAXLOC and MINLOC return 1 when given an empty array as an argument or every element of the mask is false.

`old_unit_star` The READs or WRITEs to UNIT=* go to stdin or stdout, respectively, even if UNIT=5 or 6 has been connected to another file.

`old_xor` Intrinsic operator .XOR. is defined by the compiler.

`noprotect_allocates` Memory allocation requests using the ALLOCATE statement are not protected with critical sections and may encounter random timing problems in a multi-threaded environment.

`protect_constants` A constant actual argument is passed to a called routine. Any attempt to modify it results in an error.

`noprotect_parens` The optimizer reorders REAL and COMPLEX expressions without regard for parentheses by reassociating operations if it produces faster executing code.

`realloc_lhs` Tells the compiler that when the left-hand side of an assignment is an allocatable object, it should be reallocated to the shape of the right-hand side of the assignment before the assignment occurs. This is the current Fortran Standard definition. This feature may cause extra overhead at run time. The option `standard-realloc-lhs` has the same effect as `assume realloc_lhs`.

`norecursion` Tells the compiler that all procedures are not compiled for recursion, unless declared with the RECURSIVE keyword. Fortran 2018 specifies the default mode of compilation is recursion; previous standards specified no recursion. This default will change in a future release.

`source_include` The compiler searches for USE modules and INCLUDE files in the directory where the source file is located.

`std_intent_in` The compiler assumes that dummy arguments with the INTENT(IN) attribute in a called procedure are not modified across a call, in accordance with the Fortran standard.

`std_minus0_rounding` A negative value that is not zero but rounds to zero on output is displayed with a leading minus sign. For example, the value -0.00000001 in F5.1 format will be displayed as -0.0 rather than as 0.0.

`nostd_mod_proc_name` The compiler allows the names of module procedures to conflict with user external symbol names.

`std_value` The compiler assumes that the VALUE attribute has the effect as if the actual argument is assigned to a temporary, and the temporary is then passed to the called procedure so that subsequent changes to the value of the dummy argument do not affect the actual argument, in accordance with the Fortran standard.

Windows: `nounderscore` Linux and macOS*: `underscore`	On Windows* systems, the compiler does not append an underscore character to external user-defined names. On Linux* and macOS* systems, the compiler appends an underscore character to external user-defined names.
`no2underscores` (Linux and macOS*)	The compiler does not append two underscore characters to external user-defined names that contain an embedded underscore.
`nowriteable-strings`	The compiler puts character constants into read-only memory.

Description

This option specifies assumptions to be made by the compiler.

Option	Description
`assume none`	Disables all the assume options.
`assume bscc`	Tells the compiler to treat the backslash character (\) as a C-style control (escape) character syntax in character literals. The "bscc" keyword means "BackSlashControlCharacters."
`assume buffered_io`	Tells the compiler to accumulate records in a buffer. This sets the default for opening sequential files to BUFFERED='YES', which also occurs if the FORT_BUFFERED run-time environment variable is specified. When this option is specified, the internal buffer is filled, possibly by many record input statements (READ) or output statements (WRITE), before it is read from disk, or written to disk, by the Fortran run-time system. If a file is opened for direct access, I/O buffering is ignored. Using buffered reads and writes usually makes disk I/O more efficient by handling larger blocks of data on disk less often. However, if you request buffered writes, records not yet written to disk may be lost in the event of a system failure. The OPEN statement BUFFERED specifier applies to a specific logical unit. In contrast, the `assume [no]buffered_io` option and the FORT_BUFFERED environment variable apply to all Fortran units.
`assume buffered_stdout`	Tells the Fortran run-time system to accumulate data for the standard output device in a buffer. When the buffer is full or the user executes a FLUSH on OUTPUT_UNIT in intrinsic module ISO_FORTRAN_ENV, the data is displayed on the standard output unit. Using buffered writes may be a more efficient in time and space but use `assume nobuffered_stdout` if you want data displayed immediately on the standard output device, like for an input prompt. `assume [no]buffered_stdout` does not affect and is not affected by `assume [no]buffered_io`.

Option	Description
	After compiling with this option, the default blocksize for stdout is 8 KB.
`assume byterecl`	Specifies that the units for the OPEN statement RECL specifier (record length) value are in bytes for unformatted data files, not longwords (four-byte units). For formatted files, the RECL value is always in bytes. If a file is open for unformatted data and `assume byterecl` is specified, INQUIRE returns RECL in bytes; otherwise, it returns RECL in longwords. An INQUIRE returns RECL in bytes if the unit is not open.
`assume cc_omp`	Enables conditional compilation as defined by the OpenMP Fortran API. That is, when "!$space" appears in free-form source or "c$spaces" appears in column 1 of fixed-form source, the rest of the line is accepted as a Fortran line.
`assume contiguous_assumed_shape`	Tells the compiler to assume contiguity for assumed-shape dummy arguments. This may aid in optimization. However, if you are mistaken about the contiguity of your data, it could result in run-time failures.
`assume contiguous_pointer`	Tells the compiler to assume contiguity for pointers. This may aid in optimization. However, if you are mistaken about the contiguity of your data, it could result in run-time failures.
`assume dummy_aliases`	Tells the compiler that dummy (formal) arguments to procedures share memory locations with other dummy arguments (aliases) or with variables shared through use association, host association, or common block use. Specify the option when you compile the called subprogram. The program semantics involved with dummy aliasing do not strictly obey Standard Fortran and they slow performance, so you get better run-time performance if you do not use this option. However, if a program depends on dummy aliasing and you do not specify this option, the run-time behavior of the program will be unpredictable. In such programs, the results will depend on the exact optimizations that are performed. In some cases, normal results will occur, but in other cases, results will differ because the values used in computations involving the offending aliases will differ.
`assume fpe_summary`	Causes a summary of floating-point exceptions that occurred during program execution to be displayed when a STOP or ERROR STOP statement is encountered. Counts will be shown for each exception. This is the behavior specified by the Fortran 2003 standard. Note that if there is no STOP or ERROR STOP statement, no summary is displayed.
`assume ieee_fpe_flags`	Tells the compiler to save floating-point exception and status flags on routine entry and restore them on routine exit. This option can slow runtime performance because it provides extra code to save and restore the floating-point exception and status flags (and the rounding mode) on entry to and exit from every routine compiled with the option. This option can be used to get the full Fortran Standard behavior of intrinsic modules IEEE EXCEPTIONS, IEEE ARITHMETIC, and IEEE FEATURES, which require that if a flag is signaling on routine entry, the processor will set it to quiet on entry and restore it to signaling on return. If a flag signals while the routine is executing, it will not be set to quiet on routine exit. Options `fpe` and `fpe-all` can be used to set the initial state for which floating-point exceptions will signal.

Option	Description
`assume minus0`	Tells the compiler to use Fortran 95 standard semantics for the treatment of the IEEE* floating value -0.0 in the SIGN intrinsic, which distinguishes the difference between -0.0 and +0.0, and to write a value of -0.0 with a negative sign on formatted output.
`assume old_boz`	Tells the compiler that the binary, octal, and hexadecimal constant arguments in intrinsic functions INT, REAL, DBLE, and CMPLX should be treated as signed integer constants.
`assume noold_inquire_recl`	Tells the compiler to use Fortran 2018 semantics for RECL= on an INQUIRE statement. If the unit is unconnected, the *scalar-int-variable* of the RECL= specifier becomes defined with the value -1; if the unit is connected for stream access, it becomes defined with the value -2.
`assume noold_ldout_format`	Tells the compiler to use Fortran 2003 standard semantics for output of integer and real values in list-directed and namelist-directed output. Integers are written using an I0 format with a leading blank for spacing. Real and complex values are written using and E or F format with a leading blank for spacing. The format used depends on the magnitude of the value. Values that are zero are written using an F format.
`assume noold_ldout_real`	For list-directed output of a floating-point zero, fractional format is used instead of exponential output. Early versions of the Fortran standard specified exponential format should be used for list-directed output of a floating-point zero value. Newer versions of the standard specify that fractional format should be used.
`assume old_logical_assign`	In the assignment statement L = N, where L is a logical variable and N is a numeric value, N is converted to integer if necessary, and L is assigned the bit value of the integer value without conversion. In the assignment statement N = L, where N is a variable of numeric type and L is a logical value, N is assigned the bit value of the value of L without conversion.
`assume old_logical_int`	Logical values are allowed for numeric items and numeric values are allowed for logical items.
`assume noold_maxminloc`	Tells the compiler that MAXLOC and MINLOC should return 0 when given an empty array as an argument or every element of the mask is false. Compared to the default setting (`old_maxminloc`), this behavior may slow performance because of the extra code needed to check for an empty array argument or for an all-false mask.
`assume noold_unit_star`	Tells the compiler that READs or WRITEs to UNIT=* go to the file to which UNIT=5 or 6 is connected.
`assume noold_xor`	Prevents the compiler from defining .XOR. as an intrinsic operator. This lets you use .XOR. as a user-defined operator. This is a Fortran 2003 feature.
`assume protect_allocate`	Memory allocation requests using the ALLOCATE statement are protected with critical sections to avoid random timing problems in a multi-threaded environment in some distributions and configurations.

Option	Description
`assume noprotect_constants`	Tells the compiler to pass a copy of a constant actual argument. This copy can be modified by the called routine, even though the Fortran standard prohibits such modification. The calling routine does not see any modification to the constant.
`assume protect_parens`	Tells the optimizer to honor parentheses in REAL and COMPLEX expression evaluations by not reassociating operations. For example, (A+B)+C would not be evaluated as A+(B+C). If assume noprotect_parens is specified, (A+B)+C would be treated the same as A +B+C and could be evaluated as A+(B+C) if it produced faster executing code. Such reassociation could produce different results depending on the sizes and precision of the arguments. For example, in (A+B)+C, if B and C had opposite signs and were very large in magnitude compared to A, A+B could result in the value as B; adding C would result in 0.0. With reassociation, B+C would be 0.0; adding A would result in a non-zero value.
`assume norealloc_lhs`	The compiler uses the old Fortran 2003 rules when interpreting assignment statements. The left-hand side is assumed to be allocated with the correct shape to hold the right-hand side. If it is not, incorrect behavior will occur. The option `nostandard-realloc-lhs` has the same effect as `assume norealloc_lhs`.
`assume recursion`	Tells the compiler to compile procedures that are declared without the RECURSIVE or NON_RECURSIVE keyword as recursive procedures. In Fortran 2018, these procedures are compiled for recursion by default; in previous standards they were compiled as non-recursive procedures. The current default behavior is non-recursive. This will change in a future release.
`assume nosource_include`	Tells the compiler to search the default directory for module files specified by a USE statement or source files specified by an INCLUDE statement. This option affects fpp preprocessor behavior and the USE statement.
`assume nostd_intent_in`	Tells the compiler to assume that dummy arguments with the INTENT(IN) attribute in a called procedure may be modified across a call. This is not in accordance with the Fortran standard. If you specify option `standard_semantics`, it sets option `assume std_intent_in`.
`assume nostd_minus0_rounding`	Tells the compiler to use pre-Fortran 2008 standard semantics for the treatment of IEEE* floating values that are negative, non-zero, and when rounded for display are zero. The value should be printed without a leading minus sign. For example, the floating value -0.00000001 when rounded in F5.1 format will be displayed as 0.0. Use `assume std_minus0_rounding` to use Fortran 2008 standard semantics to display this value as -0.0 when rounded in F5.1 format. `assume [no]std_minus0_rounding` does not affect and is not affected by `assume [no]minus0`. The former controls printing of a minus sign for non-zero numbers while the latter controls printing of actual signed zero values.
`assume std_mod_proc_name`	Tells the compiler to revise the names of module procedures so they do not conflict with user external symbol names. For example, procedure `proc` in module `m` would be named `m_MP_proc`. The Fortran 2003 Standard requires that module procedure names not conflict with other external symbols.

Option	Description
	By default, procedure `proc` in module `m` would be named `m_mp_proc`, which could conflict with a user-defined external name `m_mp_proc`.
`assume nostd_value`	Tells the compiler to use pre-Fortran 2003 standard semantics for the VALUE attribute so that the value of the actual argument is passed to the called procedure, not the address of the actual argument nor the address of a copy of the actual argument.
`assume underscore`	Tells the compiler to append an underscore character to external user-defined names: the main program name, named common blocks, BLOCK DATA blocks, global data names in MODULEs, and names implicitly or explicitly declared EXTERNAL. The name of a blank (unnamed) common block remains _BLNK__, and Fortran intrinsic names are not affected.
`assume 2underscores` (Linux and macOS*)	Tells the compiler to append two underscore characters to external user-defined names that contain an embedded underscore: the main program name, named common blocks, BLOCK DATA blocks, global data names in MODULEs, and names implicitly or explicitly declared EXTERNAL. The name of a blank (unnamed) common block remains _BLNK__, and Fortran intrinsic names are not affected. This option does not affect external names that do not contain an embedded underscore. By default, the compiler only appends one underscore to those names. For example, if you specify `assume 2underscores` for external names `my_program` and `myprogram`, `my_program` becomes `my_program__`, but `myprogram` becomes `myprogram_`.
`assume writeable-strings`	Tells the compiler to put character constants into non-read-only memory.

IDE Equivalent

Visual Studio: **Code Generation > Enable Recursive Routines** (`/assume:[no]recursion`)

Compatibility > Treat Backslash as Normal Character in Strings (`/assume:[no]bscc`)

Data > Assume Dummy Arguments Share Memory Locations (`/assume:dummy_aliases`)

Data > Constant Actual Arguments Can Be Changed (`/assume:noprotect_constants`)

Data > Use Bytes as RECL=Unit for Unformatted Files (`/assume:byterecl`)

External Procedures > Append Underscore to External Names (`/assume:underscore`)

Floating Point > Enable IEEE Minus Zero Support (`/assume:minus0`)

Optimization > I/O Buffering (`/assume:buffered_io`)

Preprocessor > Default Include and Use Path (`/assume:nosource_include`)

Preprocessor > OpenMP Conditional Compilation (`/assume:nocc_omp`)

Eclipse: None

Xcode: **Code Generation > Enable Recursive Routines** (`-assume [no]recursion`)

Compatibility > Treat Backslash as Normal Character in Strings (`-assume [no]bscc`)

Data > Assume Dummy Arguments Share Memory Locations (`-assume [no]dummy_aliases`)

Data > Constant Actual Arguments Can Be Changed (`-assume [no]protect_constants`)

Data > Use Bytes as RECL=Unit for Unformatted Files (`-assume [no]byterecl`)

External Procedures > Append Underscore to External Names (`-assume [no]underscore`)

Floating Point > Enable IEEE Minus Zero Support (`-assume [no]minus0`)

Optimization > I/O Buffering (`-assume [no]buffered_io`)

Preprocessor > Default Include and Use Path (`-assume [no]source_include`)

Preprocessor > OpenMP Conditional Compilation (`-assume [no]cc_omp`)

Alternate Options

`assume nobsc`
Linux and macOS*: `-nbs`
Windows: `/nbs`

`assume dummy_aliases`
Linux and macOS*: `-common-args`
Windows: `/Qcommon-args`

`assume protect_parens`
Linux and macOS*: `-fprotect-parens`
Windows: `/Qprotect-parens`

`assume realloc_lhs`
Linux and macOS*: `-standard-realloc-lhs`
Windows: `/standard-realloc-lhs`

ccdefault

Specifies the type of carriage control used when a file is displayed at a terminal screen.

Syntax

Linux OS and macOS:

`-ccdefault` *keyword*

Windows OS:

`/ccdefault:`*keyword*

Arguments

keyword Specifies the carriage-control setting to use. Possible values are:

`none` Tells the compiler to use no carriage control processing.

`default` Tells the compiler to use the default carriage-control setting.

`fortran` Tells the compiler to use normal Fortran interpretation of the first character. For example, the character 0 causes output of a blank line before a record.

`list` Tells the compiler to output one line feed between records.

Default

`ccdefault default` The compiler uses the default carriage control setting.

Description

This option specifies the type of carriage control used when a file is displayed at a terminal screen (units 6 and *). It provides the same functionality as using the CARRIAGECONTROL specifier in an OPEN statement.

The default carriage-control setting can be affected by the `vms` option. If option `vms` is specified with `ccdefault default`, carriage control defaults to normal Fortran interpretation (`ccdefault fortran`) if the file is formatted and the unit is connected to a terminal. If option `novms` (the default) is specified with `ccdefault default`, carriage control defaults to list (`ccdefault list`).

IDE Equivalent

Visual Studio: **Run-time > Default Output Carriage Control**

Eclipse: None

Xcode: **Run-time > Default Output Carriage Control**

Alternate Options

None

check

Checks for certain conditions at run time.

Syntax

Linux OS and macOS:

`-check [keyword[, keyword...]]`

`-nocheck`

Windows OS:

`/check[:keyword[, keyword...]]`

`/nocheck`

Arguments

keyword Specifies the conditions to check. Possible values are:

`none` Disables all check options.

`[no]arg_temp_created` Determines whether checking occurs for actual arguments copied into temporary storage before routine calls.

`[no]assume`	Determines whether checking occurs to test that the *scalar-Boolean-expression* in the ASSUME directive is true, or that the addresses in the ASSUME_ALIGNED directive are aligned on the specified byte boundaries.
`[no]bounds`	Determines whether checking occurs for array subscript and character substring expressions.
`[no]contiguous`	Determines whether the compiler checks pointer contiguity at pointer-assignment time.
`[no]format`	Determines whether checking occurs for the data type of an item being formatted for output.
`[no]output_conversion`	Determines whether checking occurs for the fit of data items within a designated format descriptor field.
`[no]pointers`	Determines whether checking occurs for certain disassociated or uninitialized pointers or unallocated allocatable objects.
`[no]shape`	Determines whether array conformance checking is performed.
`[no]stack`	Determines whether checking occurs on the stack frame.
`[no]udio_iostat`	Determines whether conformance checking occurs when user-defined derived type input/output routines are executed.
`[no]uninit`	Determines whether checking occurs for uninitialized variables.
`all`	Enables all check options.

Default

`nocheck`	No checking is performed for run-time failures. Note that if option `vms` is specified, the defaults are `check format` and `check output_conversion`.

Description

This option checks for certain conditions at run time.

Option	Description
`check none`	Disables all check options (same as `nocheck`).
`check arg_temp_created`	Enables run-time checking on whether actual arguments are copied into temporary storage before routine calls. If a copy is made at run-time, an informative message is displayed.
`check assume`	Enables run-time checking on whether the *scalar-Boolean-expression* in the ASSUME directive is true and that the addresses in the ASSUME_ALIGNED directive are aligned on the specified byte boundaries. If the test is .FALSE., a run-time error is reported and the execution terminates.

Option	Description
`check bounds`	Enables compile-time and run-time checking for array subscript and character substring expressions. An error is reported if the expression is outside the dimension of the array or the length of the string. For array bounds, each individual dimension is checked. For arrays that are dummy arguments, only the lower bound is checked for a dimension whose upper bound is specified as * or where the upper and lower bounds are both 1. For some intrinsics that specify a DIM= dimension argument, such as LBOUND, an error is reported if the specified dimension is outside the declared rank of the array being operated upon. Once the program is debugged, omit this option to reduce executable program size and slightly improve run-time performance. It is recommended that you do bounds checking on unoptimized code. If you use option check bounds on optimized code, it may produce misleading messages because registers (not memory locations) are used for bounds values.
`check contiguous`	Tells the compiler to check pointer contiguity at pointer-assignment time. This will help prevent programming errors such as assigning contiguous pointers to non-contiguous objects.
`check format`	Issues the run-time FORVARMIS fatal error when the data type of an item being formatted for output does not match the format descriptor being used (for example, a REAL*4 item formatted with an I edit descriptor). With `check noformat`, the data item is formatted using the specified descriptor unless the length of the item cannot accommodate the descriptor (for example, it is still an error to pass an INTEGER*2 item to an E edit descriptor).
`check output_conversion`	Issues the run-time OUTCONERR continuable error message when a data item is too large to fit in a designated format descriptor field without loss of significant digits. Format truncation occurs, the field is filled with asterisks (*), and execution continues.
`check pointers`	Enables run-time checking for disassociated or uninitialized Fortran pointers, unallocated allocatable objects, and integer pointers that are uninitialized.
`check shape`	Enables compile-time and run-time array conformance checking in contexts where it is required by the standard. These include the right-hand and left-hand side of intrinsic and elemental defined assignment, the operands of intrinsic and elemental defined binary operations, two or more array arguments to ELEMENTAL procedures, the ARRAY= and MASK= arguments to intrinsic procedures as required, and the arguments to the intrinsic module procedures IEEE_SET_FLAG and IEEE_SET_HALTING_MODE. In an ALLOCATE statement with array bounds specified for an allocate-object and with SOURCE=source specified, the allocate-object must conform with source. Note that you can specify a setting in the `warn` option to choose whether array conformance violations are diagnosed with errors or warnings.
`check stack`	Enables checking on the stack frame. The stack is checked for buffer overruns and buffer underruns. This option also enforces local variables initialization and stack pointer verification.

Option	Description
	This option disables optimization and overrides any optimization level set by option `O`.
`check udio_iostat`	Enables checking that user-defined derived type input/output routines conform to the standard's rules for assigning values to IOSTAT= and IOMSG= specifiers.
`check uninit`	Enables run-time checking for uninitialized variables. If a variable is read before it is written, a run-time error routine will be called. Only local scalar variables of intrinsic type INTEGER, REAL, COMPLEX, and LOGICAL without the SAVE attribute are checked. To detect uninitialized arrays or array elements, please see option `[Q]init` or see the article titled: Detection of Uninitialized Floating-point Variables in Intel® Fortran, which is located in https://software.intel.com/articles/detection-of-uninitialized-floating-point-variables-in-intel-fortran
`check all`	Enables all check options. This is the same as specifying `check` with no keyword. This option disables optimization and overrides any optimization level set by option `O`.

To get more detailed location information about where an error occurred, use option `traceback`.

IDE Equivalent

Visual Studio:

Run-time > Runtime Error Checking (`/nocheck`, `/check:all`)

Run-time > Check Array and String Bounds (`/check:bounds`)

Run-time > Check Uninitialized Variables (`/check:uninit`)

Run-time > Check Edit Descriptor Data Type (`/check:format`)

Run-time > Check Edit Descriptor Data Size (`/check:output_conversion`)

Run-time > Check For Actual Arguments Using Temporary Storage (`/check:arg_temp_created`)

Run-time > Check Array Conformance (`/check:shape`)

Run-time > Check For Null Pointers and Allocatable Array References (`/check:pointers`)

Eclipse: None

Xcode: **Run-time > Runtime Error Checking** (`-check all, -check none`)

Run-time > Check Array and String Bounds (`-check [no]bounds`)

Run-time > Check Edit Descriptor Data Type (`-check [no]format`)

Run-time > Check Edit Descriptor Data Size (`-check [no]output_conversion`)

Run-time > Check For Actual Arguments Using Temporary Storage (`-check [no]arg_temp_created`)

Run-time > Check Array Conformance (`-check [no]shape`)

Run-time > Check for Uninitialized Variables (`-check [no]uninit`)

Run-time > Check For Null Pointers and Allocatable Array References (`-check [no]pointers`)

Run-time > Check Stack Frame (`-check [no]stack`)

Alternate Options

`check none` Linux and macOS*: `-nocheck`
Windows: `/nocheck`

`check bounds` Linux and macOS*: `-CB`
Windows: `/CB`

`check shape` Linux and macOS*: `-CS`
Windows: `/CS`

`check uninit` Linux and macOS*: `-CU`

extend-source

Specifies the length of the statement field in a fixed-form source file.

Syntax

Linux OS and macOS:

`-extend-source [size]`

`-noextend-source`

Windows OS:

`/extend-source[:size]`

`/noextend-source`

Arguments

size	Is the length of the statement field in a fixed-form source file. Possible values are: 72, 80, or 132.

Default

72	If you do not specify this option or you specify `noextend-source`, the statement field ends at column 72.
132	If you specify `extend_source` without *size*, the statement field ends at column 132.

Description

This option specifies the size (column number) of the statement field of a source line in a fixed-form source file. This option is valid only for fixed-form files; it is ignored for free-form files.

When size is specified, it is the last column parsed as part of the statement field. Any columns after that are treated as comments.

If you do not specify *size*, it is the same as specifying `extend_source 132`.

Option	Description
`extend-source 72`	Specifies that the statement field ends at column 72.
`extend-source 80`	Specifies that the statement field ends at column 80.
`extend-source 132`	Specifies that the statement field ends at column 132.

IDE Equivalent

Visual Studio: **Language > Fixed Form Line Length**

Eclipse: None

Xcode: **Language > Fixed Form Line Length**

Alternate Options

`extend-source 72`
Linux and macOS*: `-72`
Windows: `/4L72`

`extend-source 80`
Linux and macOS*: `-80`
Windows: `/4L80`

`extend-source 132`
Linux and macOS*: `-132`
Windows: `/4L132`

fixed

Specifies source files are in fixed format.

Syntax

Linux OS and macOS:

`-fixed`

`-nofixed`

Windows OS:

`/fixed`

`/nofixed`

Arguments

None

Default

OFF The source file format is determined from the file extension.

Description

This option specifies source files are in fixed format. If this option is not specified, format is determined as follows:

- Files with an extension of .f90, .F90, or .i90 are free-format source files.
- Files with an extension of .f, .for, .FOR, .ftn, .FTN, .fpp, .FPP, or .i are fixed-format files.

Note that on Linux* and macOS* systems, file names and file extensions are case sensitive.

IDE Equivalent

Visual Studio: **Language > Source File Format** (`/free`, `/fixed`)

Eclipse: None

Xcode: **Language > Source File Format** (`/free`, `/fixed`)

Alternate Options

Linux and macOS*: `-FI`

Windows: `/nofree`, `/FI`, `/4Nf`

free

Specifies source files are in free format.

Syntax

Linux OS and macOS:

`-free`

`-nofree`

Windows OS:

`/free`

`/nofree`

Arguments

None

Default

OFF The source file format is determined from the file extension.

Description

This option specifies source files are in free format. If this option is not specified, format is determined as follows:

- Files with an extension of .f90, .F90, or .i90 are free-format source files.
- Files with an extension of .f, .for, .FOR, .ftn, or .i are fixed-format files.

IDE Equivalent

Visual Studio: **Language > Source File Format** (`/free`, `/fixed`)

Eclipse: None

Xcode: **Language > Source File Format** (`/free`, `/fixed`)

Alternate Options

Linux and macOS*: `-FR`

Windows: `/nofixed`, `/FR`, `/4Yf`

See Also

`fixed` compiler option

iface

Specifies the default calling convention and argument-passing convention for an application.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/iface:`*`keyword`*

Arguments

keyword Specifies the calling convention or the argument-passing convention. Possible values are:

`default`	Tells the compiler to use the default calling conventions.
`cref`	Tells the compiler to use calling conventions C, REFERENCE.
`cvf`	Tells the compiler to use calling conventions compatible with Compaq Visual Fortran*. This value is only available on Windows* systems.
`[no]mixed_str_len_arg`	Determines the argument-passing convention for hidden-length character arguments.
`stdcall`	Tells the compiler to use calling convention STDCALL.
`stdref`	Tells the compiler to use calling conventions STDCALL, REFERENCE.

Default

`/iface:default` The default calling convention is used.

Description

This option specifies the default calling convention and argument-passing convention for an application.

The aspects of calling and argument passing controlled by this option are as follows:

- The calling mechanism (C or STDCALL): On IA-32 architecture, these mechanisms differ in how the stack register is adjusted when a procedure call returns. On Intel® 64 architecture, the only calling mechanism available is C; requests for the STDCALL mechanism are ignored.
- The argument passing mechanism (by value or by reference)
- Character-length argument passing (at the end of the argument list or after the argument address)

- The case of external names (uppercase or lowercase)
- The name decoration (prefix and suffix)

You can also use the ATTRIBUTES compiler directive to modify these conventions on an individual basis. Note that the effects of the ATTRIBUTES directive do not always match that of the iface option of the same name.

Option	Description
`/iface:default`	Tells the compiler to use the default calling conventions. These conventions are as follows: • The calling mechanism: C • The argument passing mechanism: by reference • Character-length argument passing: at end of argument list • The external name case: uppercase • The name decoration: Underscore prefix on IA-32 architecture, no prefix on Intel® 64 architecture; no suffix
`/iface:cref`	Tells the compiler to use the same conventions as `/iface:default` except that external names are lowercase.
`/iface:cvf`	Tells the compiler to use calling conventions compatible with Compaq Visual Fortran* and Microsoft Fortran PowerStation. This option is only available on Windows* systems. These conventions are as follows: • The calling mechanism: STDCALL on Windows* systems using IA-32 architecture • The argument passing mechanism: by reference • Character-length argument passing: following the argument address • The external name case: uppercase • The name decoration: Underscore prefix on IA-32 architecture, no prefix on Intel® 64 architecture. On Windows* systems using IA-32 architecture, @n suffix where *n* is the number of bytes to be removed from the stack on exit from the procedure. No suffix on other systems.
`/iface:mixed_str_len_arg`	Specifies argument-passing conventions for hidden-length character arguments. This option tells the compiler that the hidden length passed for a character argument is to be placed immediately after its corresponding character argument in the argument list. This is the method used by Compaq Visual Fortran*. When porting mixed-language programs that pass character arguments, either this option must be specified correctly or the order of hidden length arguments must be changed in the source code. This option can be used in addition to other `/iface` options.
`/iface:stdcall`	Tells the compiler to use the following conventions: • The calling mechanism: STDCALL • The argument passing mechanism: by value • Character-length argument passing: at the end of the argument list • The external name case: uppercase • The name decoration: Underscore prefix on IA-32 architecture, no prefix on Intel® 64 architecture. On Windows* systems using IA-32 architecture, @n suffix where *n* is the number of bytes to be removed from the stack on exit from the procedure. No suffix on other systems.
`/iface:stdref`	Tells the compiler to use the same conventions as `/iface:stdcall` except that argument passing is by reference.

Caution
On Windows systems, if you specify option `/iface:cref`, it overrides the default for external names and causes them to be lowercase. It is as if you specified "!dir$ attributes c, reference" for the external name.

If you specify option `/iface:cref` and want external names to be uppercase, you must explicitly specify option `/names:uppercase`.

Caution
On systems using IA-32 architecture, there must be agreement between the calling program and the called procedure as to which calling mechanism (C or STDCALL) is used, or unpredictable errors may occur. If you change the default mechanism to STDCALL, you must use the ATTRIBUTES DEFAULT directive to reset the calling conventions for any procedure that is:

- Specified as a FINAL procedure for a derived type
- Specified as a USEROPEN procedure in an OPEN statement
- Referenced in a variable format expression
- Specified as a comparison routine passed to the QSORT library routine from module IFPORT
- Used as a dialog callback procedure with the IFLOGM module
- Called from other contexts or languages that assume the C calling convention

Note that Visual Studio projects that are imported using the *Extract Compaq Visual Fortran project items* wizard have `/iface:cvf` applied automatically; this establishes STDCALL as the default convention.

IDE Equivalent

Visual Studio: **External Procedures > Calling Convention** (`/iface:{cref|stdref|stdcall|cvf|default}`)

External Procedures > String Length Argument Passing (`/iface:[no]mixed_str_len_arg`)

Eclipse: None

Xcode: None

Alternate Options

`/iface:cvf`
Linux and macOS*: None
Windows: `/Gm`

`/iface:mixed_str_len_arg`
Linux and macOS*: `-mixed-str-len-arg`
Windows: None

`/iface:nomixed_str_len_arg`
Linux and macOS*: `-nomixed-str-len-arg`
Windows: None

`/iface:stdcall`
Linux and macOS*: None
Windows: `/Gz`

See Also

Language Reference: ATTRIBUTES

names

Specifies how source code identifiers and external names are interpreted.

Syntax

Linux OS and macOS:

`-names keyword`

Windows OS:

`/names:keyword`

Arguments

keyword Specifies how to interpret the identifiers and external names in source code. Possible values are:

`lowercase`	Causes the compiler to ignore case differences in identifiers and to convert external names to lowercase.
`uppercase`	Causes the compiler to ignore case differences in identifiers and to convert external names to uppercase.
`as_is`	Causes the compiler to distinguish case differences in identifiers and to preserve the case of external names.

Default

`lowercase`	This is the default on Linux* and macOS* systems. The compiler ignores case differences in identifiers and converts external names to lowercase.
`uppercase`	This is the default on Windows* systems. The compiler ignores case differences in identifiers and converts external names to uppercase.

Description

This option specifies how source code identifiers and external names are interpreted. It can be useful in mixed-language programming.

This naming convention applies whether names are being defined or referenced.

You can use the ALIAS directive to specify an alternate external name to be used when referring to external subprograms.

Caution
On Windows systems, if you specify option `/iface:cref`, it overrides the default for external names and causes them to be lowercase. It is as if you specified "!dir$ attributes c, reference" for the external name.

If you specify option `/iface:cref` and want external names to be uppercase, you must explicitly specify option `/names:uppercase`.

IDE Equivalent

Visual Studio: **External Procedures > Name Case Interpretation**

Eclipse: None

Xcode: **External Procedures > Name Case Interpretation**

Alternate Options

None

See Also

`iface` compiler option

ALIAS Directive

pad-source, Qpad-source

Specifies padding for fixed-form source records.

Syntax

Linux OS and macOS:

`-pad-source`

`-nopad-source`

Windows OS:

`/pad-source`

`/nopad-source`

`/Qpad-source`

`/Qpad-source-`

Arguments

None

Default

`-nopad-source` Fixed-form source records are not padded.

or
`/Qpad-source-`

Description

This option specifies padding for fixed-form source records. It tells the compiler that fixed-form source lines shorter than the statement field width are to be padded with spaces to the end of the statement field. This affects the interpretation of character and Hollerith literals that are continued across source records.

The default value setting causes a warning message to be displayed if a character or Hollerith literal that ends before the statement field ends is continued onto the next source record. To suppress this warning message, specify setting `nousage` for option `warn`.

Specifying `[Q]pad-source` can prevent warning messages associated with setting `usage` for option `warn`.

IDE Equivalent

Visual Studio: **Language > Pad Fixed Form Source Lines**

Eclipse: None

Xcode: **Language > Pad Fixed Form Source Lines**

Alternate Options

None

See Also

`warn` compiler option

stand

Tells the compiler to issue compile-time messages for nonstandard language elements.

Syntax

Linux OS and macOS:

`-stand [keyword]`

`-nostand`

Windows OS:

`/stand[:keyword]`

`/nostand`

Arguments

keyword Specifies the language to use as the standard. Possible values are:

`none`	Issues no messages for nonstandard language elements.
`f90`	Issues messages for language elements that are not standard in Fortran 90.
`f95`	Issues messages for language elements that are not standard in Fortran 95.
`f03`	Issues messages for language elements that are not standard in Fortran 2003.
`f08`	Issues messages for language elements that are not standard in Fortran 2008.
`f18`	Issues messages for language elements that are not standard in Fortran 2018. This setting was previously named `f15`.

Default

`nostand` The compiler issues no messages for nonstandard language elements.

Description

This option tells the compiler to issue compile-time messages for nonstandard language elements.

If you do not specify a keyword for `stand`, it is the same as specifying `stand f08`.

Option	Description
`stand none`	Tells the compiler to issue no messages for nonstandard language elements. This is the same as specifying `nostand`.
`stand f90`	Tells the compiler to issue messages for language elements that are not standard in Fortran 90.
`stand f95`	Tells the compiler to issue messages for language elements that are not standard in Fortran 95.
`stand f03`	Tells the compiler to issue messages for language elements that are not standard in Fortran 2003.

Option	Description
`stand f08`	Tells the compiler to issue messages for language elements that are not standard in Fortran 2008. This option is set if you specify `warn stderrors`.
`stand f18`	Tells the compiler to issue messages for language elements that are not standard in Fortran 2018. Setting `f18` was previously named `f15`.

NOTE
When you specify this option, things that are not provided for in the Fortran standard at the specified standard level are diagnosed with warnings - this includes compiler directives recognized by ifort.

These standard compliance warnings can be ignored as they are informational only and do not affect compilation.

IDE Equivalent

Visual Studio: **Diagnostics > Warn For Nonstandard Fortran**

Eclipse: None

Xcode: **Diagnostics > Warn For Nonstandard Fortran**

Alternate Options

`stand none`	Linux and macOS*: `-nostand` Windows: `/nostand`, `/4Ns`
`stand f90`	Linux and macOS*: `-std90` Windows: `/4Ys`
`stand f95`	Linux and macOS*: `-std95` Windows: None
`stand f03`	Linux and macOS*: `-std03` Windows: None
`stand f08`	Linux and macOS*: `-std08`, `-stand`, `-std` Windows: `/stand`
`stand f18` or `stand f15` (deprecated)	Linux and macOS*: `-std18` or `-std15` (deprecated) Windows: none

See Also

`warn stderrors` compiler option

standard-realloc-lhs

Determines whether the compiler uses the current Fortran Standard rules or the old Fortran 2003 rules when interpreting assignment statements.

Syntax

Linux OS and macOS:

`-standard-realloc-lhs`

`-nostandard-realloc-lhs`

Windows OS:

`/standard-realloc-lhs`

`/nostandard-realloc-lhs`

Arguments

None

Default

`standard-realloc-lhs` The compiler uses the current Fortran Standard rules when interpreting assignment statements.

Description

This option determines whether the compiler uses the current Fortran Standard rules or the old Fortran 2003 rules when interpreting assignment statements.

Option `standard-realloc-lhs` (the default), tells the compiler that when the left-hand side of an assignment is an allocatable object, it should be reallocated to the shape of the right-hand side of the assignment before the assignment occurs. This is the current Fortran Standard definition. This feature may cause extra overhead at run time. This option has the same effect as option `assume realloc_lhs`.

If you specify `nostandard-realloc-lhs`, the compiler uses the old Fortran 2003 rules when interpreting assignment statements. The left-hand side is assumed to be allocated with the correct shape to hold the right-hand side. If it is not, incorrect behavior will occur. This option has the same effect as option `assume norealloc_lhs`.

IDE Equivalent

None

Alternate Options

None

standard-semantics

Determines whether the current Fortran Standard behavior of the compiler is fully implemented.

Syntax

Linux OS and macOS:

`-standard-semantics`

Windows OS:

`/standard-semantics`

Arguments

None

Default

OFF The compiler implements most but not all of the current Fortran Standard behavior.

Description

This option determines whether the current Fortran Standard behavior of the compiler is fully implemented.

If you specify option `standard-semantics`, it enables all of the options that implement the current Fortran Standard behavior of the compiler, which is Fortran 2008 features.

Option `standard-semantics` enables option `fpscomp logicals` and the following settings for option `assume`: byterecl, fpe_summary, ieee_fpe_flags (if the `fp-model` option setting is `strict` or `precise`), minus0, noold_inquire_recl, noold_ldout_format, noold_ldout_zero, noold_maxminloc, noold_unit_star, noold_xor, protect_parens, realloc_lhs[1], std_intent_in, std_minus0_rounding[1], std_mod_proc_name, and std_value[1].

If you specify option `standard-semantics` and also explicitly specify a different setting for an affected `assume` option, the value you specify takes effect. It overrides the settings enabled by option `standard-semantics`.

IDE Equivalent

Visual Studio: **Language > Enable F2008 Semantics**

Eclipse: None

Xcode: **Language > Enable F2008 Semantics**

Alternate Options

None

See Also

`assume` compiler option
`stand` compiler option

syntax-only

Tells the compiler to check only for correct syntax.

Syntax

Linux OS and macOS:

`-syntax-only`

Windows OS:

`/syntax-only`

Arguments

None

[1] This is the default setting for this assume option.

Default

OFF Normal compilation is performed.

Description

This option tells the compiler to check only for correct syntax. It lets you do a quick syntax check of your source file.

Compilation stops after the source file has been parsed. No code is generated, no object file is produced, and some error checking done by the optimizer is bypassed.

Warnings and messages appear on `stderr`.

IDE Equivalent

None

Alternate Options

Linux: `-y`, `-fsyntax-only`, `-syntax` (this is a deprecated option)

macOS*: `-y`, `-fsyntax-only`

Windows: `/Zs`

wrap-margin

Provides a way to disable the right margin wrapping that occurs in Fortran list-directed output.

Syntax

Linux OS:

`-wrap-margin`

`-no-wrap-margin`

macOS:

`None`

Windows OS:

`/wrap-margin`

`/wrap-margin-`

Arguments

None

Default

`wrap-margin` The right margin wraps at column 80 if the record length is greater than 80 characters.

Description

This option provides a way to disable the right margin wrapping that occurs in Fortran list-directed output. By default, when the record being written becomes longer than 80 characters, the record is wrapped to a new record at what is called the "right margin".

Specify `-no-wrap-margin` (Linux*) or `/wrap-margin-` (Windows*) to disable this behavior.

IDE Equivalent

None

Alternate Options

None

Data Options

align

Tells the compiler how to align certain data items.

Syntax

Linux OS and macOS:

`-align [keyword[, keyword...]]`

`-noalign`

Windows OS:

`/align[:keyword[, keyword...]]`

`/noalign`

Arguments

keyword Specifies the data items to align. Possible values are:

`none`	Prevents padding bytes anywhere in common blocks and structures.
`array`*n*`byte`	Specifies a starting boundary for arrays.
`[no]commons`	Affects alignment of common block entities.
`[no]dcommons`	Affects alignment of common block entities.
`[no]qcommons`	Affects alignment of common block entities.
`[no]zcommons`	Affects alignment of common block entities.
`[no]records`	Affects alignment of derived-type components and fields of record structures.
`rec`*n*`byte`	Specifies a size boundary for derived-type components and fields of record structures.
`[no]sequence`	Affects alignment of sequenced derived-type components.
`all`	Adds padding bytes whenever possible to data items in common blocks and structures.

Default

`nocommons` Adds no padding bytes for alignment of common blocks.

`nodcommmons` Adds no padding bytes for alignment of common blocks.

`noqcommmons` Adds no padding bytes for alignment of common blocks.

`nozcommmons` Adds no padding bytes for alignment of common blocks.

`records` Aligns derived-type components and record structure fields on default natural boundaries.

`nosequence` Causes derived-type components declared with the SEQUENCE statement to be packed, regardless of current alignment rules set by the user.

By default, no padding is added to common blocks but padding is added to structures.

Description

This option specifies the alignment to use for certain data items. The compiler adds padding bytes to perform the alignment.

Option	Description
`align none`	Tells the compiler not to add padding bytes anywhere in common blocks or structures. This is the same as specifying `noalign`.
`align array`*n*`byte`	Aligns the start of arrays on an *n*-byte boundary. *n* can be 8, 16, 32, 64, 128, or 256. The default value for *n* is 8. This affects the starting alignment for all arrays except for arrays in COMMON. Arrays do not have padding between their elements.
`align commons`	Aligns all common block entities on natural boundaries up to 4 bytes, by adding padding bytes as needed. The `align nocommons` option adds no padding to common blocks. In this case, unaligned data can occur unless the order of data items specified in the COMMON statement places the largest numeric data item first, followed by the next largest numeric data (and so on), followed by any character data.
`align dcommons`	Aligns all common block entities on natural boundaries up to 8 bytes, by adding padding bytes as needed. The `align nodcommons` option adds no padding to common blocks.
`align qcommons`	Aligns all common block entities on natural boundaries up to 16 bytes, by adding padding bytes as needed. The `align noqcommons` option adds no padding to common blocks.
`align zcommons`	Aligns all common block entities on natural boundaries up to 32 bytes, by adding padding bytes as needed. The `align nozcommons` option adds no padding to common blocks.
`align norecords`	Aligns components of derived types and fields within record structures on arbitrary byte boundaries with no padding.

Option	Description
	The align records option requests that multiple data items in record structures and derived-type structures without the SEQUENCE statement be naturally aligned, by adding padding as needed.
`align rec`*n*`byte`	Aligns components of derived types and fields within record structures on the smaller of the size boundary specified (*n*) or the boundary that will naturally align them. *n* can be 1, 2, 4, 8, 16, or 32. The default value for *n* is 8. When you specify this option, each structure member after the first is stored on either the size of the member type or *n*-byte boundaries, whichever is smaller. For example, to specify 16 bytes as the packing boundary (or alignment constraint) for all structures and unions in the file prog1.f, use the following command: `ifort {-align rec16byte | /align:rec16byte} prog1.f` This option does not affect whether common blocks are naturally aligned or packed.
`align sequence`	Aligns components of a derived type declared with the SEQUENCE statement (sequenced components) according to the alignment rules that are currently in use. The default alignment rules are to align unsequenced components on natural boundaries. The `align nosequence` option requests that sequenced components be packed regardless of any other alignment rules. Note that `align none` implies `align nosequence`. If you specify an option for standards checking, `align sequence` is ignored.
`align all`	Tells the compiler to add padding bytes whenever possible to obtain the natural alignment of data items in common blocks, derived types, and record structures. Specifies `align dcommons, align records, align nosequence`. This is the same as specifying `align` with no *keyword*.

IDE Equivalent

Visual Studio: **Data > Structure Member Alignment** (/align:recnbyte)

Data > Alignment of COMMON block entities (/align:[no]commons, /align:[no]dcommons, /align:[no]qcommons, /align:[no]zcommons)

Data > SEQUENCE Types Obey Alignment Rules (/align:[no]sequence)

Data > Default Array Alignment (/align:arraynbyte)

Eclipse: None

Xcode: **Data > Structure Member Alignment** (-align rec<1,2,4,8,16,32>byte)

Data > Alignment of COMMON block entities (-align [no]commons, -align [no]dcommons, -align [no]qcommons, -align [no]zcommons)

Data > SEQUENCE Types Obey Alignment Rules (-align [no]sequence)

Data > Default Array Alignment (-align array<8,16,32,64,128,256>byte)

Alternate Options

`align none`
Linux and macOS*: `-noalign`
Windows: `/noalign`

`align records`
Linux and macOS*: `-align rec16byte`, `-Zp16`

	Windows: `/align:rec16byte`, `/Zp16`
`align norecords`	Linux and macOS*: `-Zp1`, `-align rec1byte`
	Windows: `/Zp1`, `/align:rec1byte`
`align rec`*`n`*`byte`	Linux and macOS*: `-Zp{1|2|4|8|16}`
	Windows: `/Zp{1|2|4|8|16}`
`align all`	Linux and macOS*: `-align commons-align dcommons-align records-align nosequence`
	Windows: `/align:nocommons,dcommons,records,nosequence`

auto

Causes all local, non-SAVEd variables to be allocated to the run-time stack.

Syntax

Linux OS and macOS:

`-auto`

`-noauto`

Windows OS:

`/auto`

`/noauto`

Arguments

None

Default

`-auto-scalar` or `/Qauto-scalar`	Scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL are allocated to the run-time stack. Note that the default changes to `auto` if one of the following options are specified: • `recursive` • `[q or Q]openmp`

Description

This option places local variables (scalars and arrays of all types), except those declared as SAVE, on the run-time stack. It is as if the variables were declared with the AUTOMATIC attribute.

It does not affect variables that have the SAVE attribute or ALLOCATABLE attribute, or variables that appear in an EQUIVALENCE statement or in a common block.

This option may provide a performance gain for your program, but if your program depends on variables having the same value as the last time the routine was invoked, your program may not function properly.

If you want to cause variables to be placed in static memory, specify option `[Q]save`. If you want only scalar variables of certain intrinsic types to be placed on the run-time stack, specify option `auto-scalar`.

NOTE
On Windows NT* systems, there is a performance penalty for addressing a stack frame that is too large. This penalty may be incurred with `/[Q]auto`, because arrays are allocated on the stack along with scalars. However, with `/Qauto-scalar`, you would have to have more than 32K bytes of local scalar variables before you incurred the performance penalty. `/Qauto-scalar` enables the compiler to make better choices about which variables should be kept in registers during program execution.

IDE Equivalent

Visual Studio: **Data > Local Variable Storage**

Eclipse: None

Xcode: **Data > Local Variable Storage**

Alternate Options

`auto`	Linux and macOS*: None Windows: `/Qauto`, `/4Ya`
`noauto`	Linux and macOS*: `-save` Windows: `/Qsave`, `/4Na`

See Also

`auto-scalar, Qauto-scalar` compiler option
`save, Qsave` compiler option

auto-scalar, Qauto-scalar

Causes scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL that do not have the SAVE attribute to be allocated to the run-time stack.

Syntax

Linux OS and macOS:

`-auto-scalar`

Windows OS:

`/Qauto-scalar`

Arguments

None

Default

`-auto-scalar` or `/Qauto-scalar`

Scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL that do not have the SAVE attribute are allocated to the run-time stack. Note that the default changes to `auto` if one of the following options are specified:

- `recursive`
- `[q or Q]openmp`

Description

This option causes allocation of scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL to the run-time stack. It is as if they were declared with the AUTOMATIC attribute.

It does not affect variables that have the SAVE attribute (which include initialized locals) or that appear in an EQUIVALENCE statement or in a common block.

This option may provide a performance gain for your program, but if your program depends on variables having the same value as the last time the routine was invoked, your program may not function properly. Variables that need to retain their values across subroutine calls should appear in a SAVE statement.

You cannot specify option `save` or `auto` with this option.

> **NOTE**
> On Windows NT* systems, there is a performance penalty for addressing a stack frame that is too large. This penalty may be incurred with `[Q]auto` because arrays are allocated on the stack along with scalars. However, with `/Qauto-scalar`, you would have to have more than 32K bytes of local scalar variables before you incurred the performance penalty. `/Qauto-scalar` enables the compiler to make better choices about which variables should be kept in registers during program execution.

IDE Equivalent

Visual Studio: **Data > Local Variable Storage** (`/Qsave`, `/Qauto`, `/Qauto_scalar`)

Eclipse: None

Xcode: **Data > Local Variable Storage**

Alternate Options

None

See Also

`auto` compiler option

`save` compiler option

convert

Specifies the format of unformatted files containing numeric data.

Syntax

Linux OS and macOS:

`-convert` *keyword*

Windows OS:

`/convert:`*keyword*

Arguments

keyword Specifies the format for the unformatted numeric data. Possible values are:

`native` Specifies that unformatted data should not be converted.

`big_endian`	Specifies that the format will be big endian for integer data and big endian IEEE floating-point for real and complex data.
`cray`	Specifies that the format will be big endian for integer data and CRAY* floating-point for real and complex data.
`fdx` (Linux*, macOS*)	Specifies that the format will be little endian for integer data, and VAX processor floating-point format F_floating, D_floating, and IEEE binary128 for real and complex data.
`fgx` (Linux, macOS*)	Specifies that the format will be little endian for integer data, and VAX processor floating-point format F_floating, G_floating, and IEEE binary128 for real and complex data.
`ibm`	Specifies that the format will be big endian for integer data and IBM* System\370 floating-point format for real and complex data.
`little_endian`	Specifies that the format will be little endian for integer data and little endian IEEE floating-point for real and complex data.
`vaxd`	Specifies that the format will be little endian for integer data, and VAX* processor floating-point format F_floating, D_floating, and H_floating for real and complex data.
`vaxg`	Specifies that the format will be little endian for integer data, and VAX processor floating-point format F_floating, G_floating, and H_floating for real and complex data.

Default

`convert native` No conversion is performed on unformatted files containing numeric data.

Description

This option specifies the format of unformatted files containing numeric data.

Option	Description
`convert native`	Specifies that unformatted data should not be converted.
`convert big_endian`	Specifies that the format will be big endian for INTEGER*1, INTEGER*2, INTEGER*4, or INTEGER*8, and big endian IEEE floating-point for REAL*4, REAL*8, REAL*16, COMPLEX*8, COMPLEX*16, or COMPLEX*32.
`convert cray`	Specifies that the format will be big endian for INTEGER*1, INTEGER*2, INTEGER*4, or INTEGER*8, and CRAY* floating-point for REAL*8 or COMPLEX*16.
`convert fdx`	Specifies that the format will be little endian for INTEGER*1, INTEGER*2, INTEGER*4, or INTEGER*8, and VAX processor floating-point format F_floating for REAL*4 or COMPLEX*8, D_floating for REAL*8 or COMPLEX*16, and IEEE binary128 for REAL*16 or COMPLEX*32.
`convert fgx`	Specifies that the format will be little endian for INTEGER*1, INTEGER*2, INTEGER*4, or INTEGER*8, and VAX processor floating-point format F_floating for REAL*4 or COMPLEX*8, G_floating for REAL*8 or COMPLEX*16, and IEEE binary128 for REAL*16 or COMPLEX*32.

Option	Description
`convert ibm`	Specifies that the format will be big endian for INTEGER*1, INTEGER*2, or INTEGER*4, and IBM* System\370 floating-point format for REAL*4 or COMPLEX*8 (IBM short 4) and REAL*8 or COMPLEX*16 (IBM long 8).
`convert little_endian`	Specifies that the format will be little endian for INTEGER*1, INTEGER*2, INTEGER*4, or INTEGER*8 and little endian IEEE floating-point for REAL*4, REAL*8, REAL*16, COMPLEX*8, COMPLEX*16, or COMPLEX*32.
`convert vaxd`	Specifies that the format will be little endian for INTEGER*1, INTEGER*2, INTEGER*4, or INTEGER*8, and VAX processor floating-point format F_floating for REAL*4 or COMPLEX*8, D_floating for REAL*8 or COMPLEX*16, and H_floating for REAL*16 or COMPLEX*32.
`convert vaxg`	Specifies that the format will be little endian for INTEGER*1, INTEGER*2, INTEGER*4, or INTEGER*8, and VAX processor floating-point format F_floating for REAL*4 or COMPLEX*8, G_floating for REAL*8 or COMPLEX*16, and H_floating for REAL*16 or COMPLEX*32.

Non-native data conversion works on scalars and arrays of intrinsic types: INTEGER*1, INTEGER*2, INTEGER*4, INTEGER*8, including LOGICAL*1, LOGICAL*2, LOGICAL*4, LOGICAL*8, and REAL*4, REAL*8, REAL*16, including COMPLEX*8, COMPLEX*16, and COMPLEX*32. Conversion does not work inside defined type records on their individual fields. For example:

```
type REC
   integer(8) :: K
   real(8)    :: X
end type REC

type (REC) :: R

write (17) R%K, R%X    ! conversion will work on these objects
write (17) R           ! conversion will not work on the fields of this object
```

IDE Equivalent

Visual Studio: **Compatibility > Unformatted File Conversion**

Eclipse: None

Xcode: **Compatibility > Unformatted File Conversion**

Alternate Options

None

double-size

Specifies the default KIND for DOUBLE PRECISION and DOUBLE COMPLEX declarations, constants, functions, and intrinsics.

Syntax

Linux OS and macOS:

`-double-size` *size*

Windows OS:

`/double-size:`*size*

Arguments

size	Specifies the default KIND for DOUBLE PRECISION and DOUBLE COMPLEX declarations, constants, functions, and intrinsics. Possible values are: 64 (KIND=8) or 128 (KIND=16).

Default

64	DOUBLE PRECISION variables are defined as REAL*8 and DOUBLE COMPLEX variables are defined as COMPLEX*16.

Description

This option defines the default KIND for DOUBLE PRECISION and DOUBLE COMPLEX declarations, constants, functions, and intrinsics.

Option	Description
`double-size 64`	Defines DOUBLE PRECISION declarations, constants, functions, and intrinsics as REAL(KIND=8) (REAL*8) and defines DOUBLE COMPLEX declarations, functions, and intrinsics as COMPLEX(KIND=8) (COMPLEX*16).
`double-size 128`	Defines DOUBLE PRECISION declarations, constants, functions, and intrinsics as REAL(KIND=16) (REAL*16) and defines DOUBLE COMPLEX declarations, functions, and intrinsics as COMPLEX(KIND=16) (COMPLEX*32).

The `real-size` option overrides the `double-size` option; for example, on Linux* systems, "-double-size 64 -real-size 128" acts like "-double-size 128 -real-size 128".

IDE Equivalent

Visual Studio: **Data > Default Double Precision KIND**

Eclipse: None

Xcode: **Data > Default Double Precision KIND**

Alternate Options

None

dyncom, Qdyncom

Enables dynamic allocation of common blocks at run time.

Syntax

Linux OS and macOS:

`-dyncom "`*`common1`*`,`*`common2`*`,..."`

Windows OS:

`/Qdyncom "`*`common1`*`,`*`common2`*`,..."`

Arguments

common1, *common2*, ...	Are the names of the common blocks to be dynamically allocated. The list of names must be within quotes.

Default

OFF Common blocks are not dynamically allocated at run time.

Description

This option enables dynamic allocation of the specified common blocks at run time. For example, to enable dynamic allocation of common blocks a, b, and c at run time, use this syntax:

```
/Qdyncom "a,b,c"    ! on Windows systems
-dyncom "a,b,c"     ! on Linux and macOS* systems
```

The following are some limitations that you should be aware of when using this option:

- An entity in a dynamic common cannot be initialized in a DATA statement.
- Only named common blocks can be designated as dynamic COMMON.
- An entity in a dynamic common block must not be used in an EQUIVALENCE expression with an entity in a static common block or a DATA-initialized variable.

NOTE
On macOS* systems, to successfully enable dynamic allocation of common blocks, you must specify the link-time option `-undefined dynamic_lookup` as well as option `-dyncom`.

IDE Equivalent

Visual Studio: **Data > Dynamic Common Blocks**

Eclipse: None

Xcode: **Data > Dynamic Common Blocks**

Alternate Options

None

See Also

Allocating Common Blocks
FOR__SET_FTN_ALLOC

falign-functions, Qfnalign

Tells the compiler to align procedures on an optimal byte boundary.

Syntax

Linux OS and macOS:

`-falign-functions[=n]`

`-fno-align-functions`

Windows OS:

`/Qfnalign[:n]`

`/Qfnalign-`

Arguments

n	Is an optional positive integer scalar initialization expression indicating the number of bytes for the minimum alignment boundary. It tells the compiler to align procedures on a power-of-2 byte boundary. If you do not specify *n*, the compiler aligns the start of procedures on 16-byte boundaries. The *n* must be a positive integer less than or equal to 4096. If you specify a value that is not a power of 2, *n* will be rounded up to the nearest power of 2. For example, if 23 is specified for *n*, procedures will be aligned on 32 byte boundaries.

Default

`-fno-align-functions` or `/Qfnalign-`	The compiler aligns procedures on 2-byte boundaries. This is the same as specifying `-falign-functions=2` (Linux* and macOS*) or `/Qfnalign:2` (Windows*).

Description

This option tells the compiler to align procedures on an optimal byte boundary. If you do not specify *n*, the compiler aligns the start of procedures on 16-byte boundaries.

IDE Equivalent

None

Alternate Options

None

falign-loops, Qalign-loops

Aligns loops to a power-of-two byte boundary.

Syntax

Linux OS and macOS:

`-falign-loops[=n]`

`-fno-align-loops`

Windows OS:

`/Qalign-loops[:n]`

`/Qalign-loops-`

Arguments

`n`	Is the optional number of bytes for the minimum alignment boundary. It must be a power of 2 between 1 and 4096, such as 1, 2, 4, 8, 16, 32, 64, 128, and so on. If you specify 1 for `n`, no alignment is performed; this is the same as specifying the negative form of the option. If you do not specify `n`, the default alignment is 16 bytes.

Default

`-fno-align-loops` No special loop alignment is performed.

or
`/Qalign-loops-`

Description

This option aligns loops to a power-of-two boundary. This alignment may improve performance.

It can be affected by the directives CODE_ALIGN and ATTRIBUTES CODE_ALIGN.

If code is compiled with the `-falign-loops=m` (Linux* and macOS*) or `/Qalign-loops:m` (Windows*) option and a CODE_ALIGN:n directive precedes a loop, the loop is aligned on a MAX (m, n) byte boundary. If a procedure has the CODE_ALIGN:k attribute and a CODE_ALIGN:n directive precedes a loop, then both the procedure and the loop are aligned on a MAX (k, n) byte boundary.

IDE Equivalent

None

Alternate Options

None

Example

Consider the following code fragment in file `test_align_loops.f90`:

```
DO J = 1, N
…
END DO
```

Compiling `test_align_loops.f90` with the `-falign-loops` (Linux and macOS*) or `/Qalign-loops` (Windows) compiler option aligns the code that begins the DO J loop on a (default) 16-byte boundary. If you do not specify this compiler option, the alignment of the loop is implementation-dependent and may change from compilation to compilation.

See Also

falign-functions, Qfnalign compiler option
CODE_ALIGN directive
ATTRIBUTES CODE_ALIGN directive

falign-stack

Tells the compiler the stack alignment to use on entry to routines.

Architecture Restrictions

Only available on IA-32 architecture

Syntax

Linux OS:

`-falign-stack=`*mode*

macOS:

None

Windows OS:

None

Arguments

mode Is the method to use for stack alignment. Possible values are:

`assume-4-byte`	Tells the compiler to assume the stack is aligned on 4-byte boundaries. The compiler can dynamically adjust the stack to 16-byte alignment if needed.
`maintain-16-byte`	Tells the compiler to not assume any specific stack alignment, but attempt to maintain alignment in case the stack is already aligned. The compiler can dynamically align the stack if needed. This setting is compatible with gcc.
`assume-16-byte`	Tells the compiler to assume the stack is aligned on 16-byte boundaries and to continue to maintain 16-byte alignment. This setting is compatible with gcc.

Default

`-falign-stack=assume-16-byte` The compiler assumes the stack is aligned on 16-byte boundaries and continues to maintain 16-byte alignment.

Description

This option tells the compiler the stack alignment to use on entry to routines.

IDE Equivalent

None

Alternate Options

None

fcommon

Determines whether the compiler treats common symbols as global definitions.

Syntax

Linux OS:

`-fcommon`

`-fno-common`

macOS:

`-fcommon`

`-fno-common`

Windows OS:

None

Arguments

None

Default

`-fcommon` The compiler does not treat common symbols as global definitions.

Description

This option determines whether the compiler treats common symbols as global definitions and to allocate memory for each symbol at compile time.

Option `-fno-common` tells the compiler to treat common symbols as global definitions. When using this option, you can only have a common variable declared in one module; otherwise, a link time error will occur for multiple defined symbols.

On macOS*, if a library built with the `ar` utility contains objects with Fortran module data but no executable functions, the symbols corresponding to the module data may not be resolved when an object referencing them is linked against the library. You can work around this by compiling with option `-fno-common`. For more information, see the article titled: *ld: symbol(s) not found when linking library containing no executable functions*, which is located in https://software.intel.com/en-us/articles/ld-symbols-not-found-when-linking-library-containing-no-executable-functions

IDE Equivalent

None

Alternate Options

None

fkeep-static-consts, Qkeep-static-consts

Tells the compiler to preserve allocation of variables that are not referenced in the source.

Syntax

Linux OS:

```
-fkeep-static-consts
-fno-keep-static-consts
```

macOS:

```
-fkeep-static-consts
-fno-keep-static-consts
```

Windows OS:

```
/Qkeep-static-consts
/Qkeep-static-consts-
```

Arguments

None

Default

`-fno-keep-static-consts` or `/Qkeep-static-consts-`	If a variable is never referenced in a routine, the variable is discarded unless optimizations are disabled by option `-O0` (Linux* and macOS*) or `/Od` (Windows*).

Description

This option tells the compiler to preserve allocation of variables that are not referenced in the source.

The negated form can be useful when optimizations are enabled to reduce the memory usage of static data.

IDE Equivalent

None

Alternate Options

None

fmath-errno

Tells the compiler that errno can be reliably tested after calls to standard math library functions.

Syntax

Linux OS:

`-fmath-errno`

`-fno-math-errno`

macOS:

`-fmath-errno`

`-fno-math-errno`

Windows OS:

`None`

Arguments

None

Default

`-fno-math-errno`	The compiler assumes that the program does not test `errno` after calls to standard math library functions.

Description

This option tells the compiler to assume that the program tests `errno` after calls to math library functions. This restricts optimization because it causes the compiler to treat most math functions as having side effects.

Option `-fno-math-errno` tells the compiler to assume that the program does not test `errno` after calls to math library functions. This frequently allows the compiler to generate faster code. Floating-point code that relies on IEEE exceptions instead of `errno` to detect errors can safely use this option to improve performance.

IDE Equivalent

None

Alternate Options

None

fminshared

Specifies that a compilation unit is a component of a main program and should not be linked as part of a shareable object.

Syntax

Linux OS and macOS:

`-fminshared`

Windows OS:

`None`

Arguments

None

Default

OFF Source files are compiled together to form a single object file.

Description

This option specifies that a compilation unit is a component of a main program and should not be linked as part of a shareable object.

This option allows the compiler to optimize references to defined symbols without special visibility settings. To ensure that external and common symbol references are optimized, you need to specify visibility hidden or protected by using the `-fvisibility`, `-fvisibility-hidden`, or `-fvisibility-protected` option.

Also, the compiler does not need to generate position-independent code for the main program. It can use absolute addressing, which may reduce the size of the global offset table (GOT) and may reduce memory traffic.

IDE Equivalent

None

Alternate Options

None

See Also

`fvisibility` compiler option

fpconstant

Tells the compiler that single-precision constants assigned to double-precision variables should be evaluated in double precision.

Syntax

Linux OS and macOS:

`-fpconstant`

`-nofpconstant`

Windows OS:

`/fpconstant`

`/nofpconstant`

Arguments

None

Default

`nofpconstant` Single-precision constants assigned to double-precision variables are evaluated in single precision according to Fortran 2003 Standard rules.

Description

This option tells the compiler that single-precision constants assigned to double-precision variables should be evaluated in double precision.

This is extended precision. It does not comply with the Fortran 2003 standard, which requires that single-precision constants assigned to double-precision variables be evaluated in single precision.

It allows compatibility with FORTRAN 77, where such extended precision was allowed. If this option is not used, certain programs originally created for FORTRAN 77 compilers may show different floating-point results because they rely on the extended precision for single-precision constants assigned to double-precision variables.

IDE Equivalent

Visual Studio: **Floating-Point > Extend Precision of Single-Precision Constants**

Eclipse: None

Xcode: **Floating-Point > Extend Precision of Single-Precision Constants**

Alternate Options

None

Example

In the following example, if you specify `fpconstant`, identical values are assigned to D1 and D2. If you omit `fpconstant`, the compiler will obey the Fortran 2003 Standard and assign a less precise value to D1:

```
REAL (KIND=8) D1, D2
DATA D1 /2.71828182846182/ ! REAL (KIND=4) value expanded to double
DATA D2 /2.71828182846182D0/ ! Double value assigned to double
```

fpic

Determines whether the compiler generates position-independent code.

Syntax

Linux OS:

`-fpic`

`-fno-pic`

macOS:

`-fpic`

`-fno-pic`

Windows OS:

`None`

Arguments

None

Default

`-fno-pic`	The compiler does not generate position-independent code.

Description

This option determines whether the compiler generates position-independent code.

Option `-fpic` specifies full symbol preemption. Global symbol definitions as well as global symbol references get default (that is, preemptable) visibility unless explicitly specified otherwise.

Option `-fpic` must be used when building shared objects.

This option can also be specified as `-fPIC`.

IDE Equivalent

None

Alternate Options

None

fpie

Tells the compiler to generate position-independent code. The generated code can only be linked into executables.

Syntax

Linux OS:

`-fpie`

macOS:

`None`

Windows OS:

`None`

Arguments

None

Default

OFF	The compiler does not generate position-independent code for an executable-only object.

Description

This option tells the compiler to generate position-independent code. It is similar to `-fpic`, but code generated by `-fpie` can only be linked into an executable.

Because the object is linked into an executable, this option causes better optimization of some symbol references.

To ensure that run-time libraries are set up properly for the executable, you should also specify option `-pie` to the compiler driver on the link command line.

Option `-fpie` can also be specified as `-fPIE`.

IDE Equivalent

None

Alternate Options

None

pie
compiler option

fstack-protector

Enables or disables stack overflow security checks for certain (or all) routines.

Syntax

Linux OS:

`-fstack-protector[-keyword]`

`-fno-stack-protector[-keyword]`

macOS:

`-fstack-protector[-keyword]`

`-fno-stack-protector[-keyword]`

Windows OS:

`None`

Arguments

keyword	Possible values are:

`strong`	When option `-fstack-protector-strong` is specified, it enables stack overflow security checks for routines with any type of buffer.
`all`	When option `-fstack-protector-all` is specified, it enables stack overflow security checks for every routine.

If no `-keyword` is specified, option `-fstack-protector` enables stack overflow security checks for routines with a string buffer.

Default

`-fno-stack-protector`, `-fno-stack-protector-strong`	No stack overflow security checks are enabled for the relevant routines.
`-fno-stack-protector-all`	No stack overflow security checks are enabled for any routines.

Description

This option enables or disables stack overflow security checks for certain (or all) routines. A stack overflow occurs when a program stores more data in a variable on the execution stack than is allocated to the variable. Writing past the end of a string buffer or using an index for an array that is larger than the array bound could cause a stack overflow and security violations.

The `-fstack-protector` options are provided for compatibility with gcc. They use the gcc/glibc implementation when possible. If the gcc/glibc implementation is not available, they use the Intel implementation.

For an Intel-specific version of this feature, see option `-fstack-security-check`.

IDE Equivalent

None

Alternate Options

None

See Also

`fstack-security-check` compiler option

`GS` compiler option

fstack-security-check

Determines whether the compiler generates code that detects some buffer overruns.

Syntax

Linux OS:

`-fstack-security-check`

`-fno-stack-security-check`

macOS:

`-fstack-security-check`

`-fno-stack-security-check`

Windows OS:

None

Arguments

None

Default

`-fno-stack-security-check`	The compiler does not detect buffer overruns.

Description

This option determines whether the compiler generates code that detects some buffer overruns that overwrite the return address. This is a common technique for exploiting code that does not enforce buffer size restrictions.

This option always uses an Intel implementation.

For a gcc-compliant version of this feature, see option `fstack-protector`.

IDE Equivalent

None

Alternate Options

Linux and macOS*: None

Windows: `/GS`

See Also

`fstack-protector` compiler option

`GS` compiler option

fvisibility

Specifies the default visibility for global symbols or the visibility for symbols in a file.

Syntax

Linux OS and macOS:

`-fvisibility=`*`keyword`*

`-fvisibility-`*`keyword=filename`*

Windows OS:

None

Arguments

keyword	Specifies the visibility setting. Possible values are:
`default`	Sets visibility to default.
`extern`	Sets visibility to extern.
`hidden`	Sets visibility to hidden.

	`internal`	Sets visibility to internal.
	`protected`	Sets visibility to protected. This value is not available on macOS* systems.
filename		Is the pathname of a file containing the list of symbols whose visibility you want to set. The symbols must be separated by whitespace (spaces, tabs, or newlines).

Default

-fvisibility=default	The compiler sets visibility of symbols to default.

Description

This option specifies the default visibility for global symbols (syntax `-fvisibility=`*keyword*) or the visibility for symbols in a file (syntax `-fvisibility-`*keyword*`=`*filename*).

Visibility specified by `-fvisibility-`*keyword*`=`*filename* overrides visibility specified by `-fvisibility=`*keyword* for symbols specified in a file.

Option	Description
`-fvisibility=default` `-fvisibility-default=`*filename*	Sets visibility of symbols to default. This means other components can reference the symbol, and the symbol definition can be overridden (preempted) by a definition of the same name in another component.
`-fvisibility=extern` `-fvisibility-extern=`*filename*	Sets visibility of symbols to extern. This means the symbol is treated as though it is defined in another component. It also means that the symbol can be overridden by a definition of the same name in another component.
`-fvisibility=hidden` `-fvisibility-hidden=`*filename*	Sets visibility of symbols to hidden. This means that other components cannot directly reference the symbol. However, its address may be passed to other components indirectly.
`-fvisibility=internal` `-fvisibility-internal=`*filename*	Sets visibility of symbols to internal. This means that the symbol cannot be referenced outside its defining component, either directly or indirectly. The affected functions can never be called from another module, including through function pointers.
`-fvisibility=protected` `-fvisibility-protected=`*filename*	Sets visibility of symbols to protected. This means other components can reference the symbol, but it cannot be overridden by a definition of the same name in another component. This value is not available on macOS* systems.

If an `-fvisibility` option is specified more than once on the command line, the last specification takes precedence over any others.

If a symbol appears in more than one visibility *filename*, the setting with the least visibility takes precedence.

The following shows the precedence of the visibility settings (from greatest to least visibility):

- `extern`
- `default`
- `protected`
- `hidden`
- `internal`

Note that `extern` visibility only applies to functions. If a variable symbol is specified as `extern`, it is assumed to be `default`.

IDE Equivalent

None

Alternate Options

None

Example

A file named `prot.txt` contains symbols a, b, c, d, and e. Consider the following:

```
-fvisibility-protected=prot.txt
```

This option sets `protected` visibility for all the symbols in the file. It has the same effect as specifying `fvisibility=protected` in the declaration for each of the symbols.

fzero-initialized-in-bss, Qzero-initialized-in-bss

Determines whether the compiler places in the DATA section any variables explicitly initialized with zeros.

Syntax

Linux OS:

`-fzero-initialized-in-bss`

`-fno-zero-initialized-in-bss`

macOS:

`-fzero-initialized-in-bss`

`-fno-zero-initialized-in-bss`

Windows OS:

`/Qzero-initialized-in-bss`

`/Qzero-initialized-in-bss-`

Arguments

None

Default

`-fno-zero-initialized-in-bss` or `/Qzero-initialized-in-bss -`

Variables explicitly initialized with zeros are placed in the BSS section. This can save space in the resulting code.

Description

This option determines whether the compiler places in the DATA section any variables explicitly initialized with zeros.

If option `-fno-zero-initialized-in-bss` (Linux* and macOS*) or `/Qzero-initialized-in-bss-` (Windows*) is specified, the compiler places in the DATA section any variables that are initialized to zero.

IDE Equivalent

Visual Studio: None

Eclipse: None

Xcode: **Data > Place Zero-Initialized Variables in .bss**

Alternate Options

None

Gs

Lets you control the threshold at which the stack checking routine is called or not called.

Syntax

Linux OS:

`None`

macOS:

`None`

Windows OS:

`/Gs[n]`

Arguments

n	Is the number of bytes that local variables and compiler temporaries can occupy before stack checking is activated. This is called the *threshold*.

Default

`/Gs`	Stack checking occurs for routines that require more than 4KB (4096 bytes) of stack space. This is also the default if you do not specify *n*.

Description

This option lets you control the threshold at which the stack checking routine is called or not called. If a routine's local stack allocation exceeds the threshold (*n*), the compiler inserts a __chkstk() call into the prologue of the routine.

IDE Equivalent

None

Alternate Options

None

GS

Determines whether the compiler generates code that detects some buffer overruns.

Syntax

Linux OS:

None

macOS:

None

Windows OS:

/GS[:*keyword*]

/GS-

Arguments

keyword Specifies the level of stack protection heuristics used by the compiler. Possible values are:

off	Tells the compiler to ignore buffer overruns. This is the same as specifying /GS-.
partial	Tells the compiler to provide a stack protection level that is compatible with Microsoft* Visual Studio 2008.
strong	Tells the compiler to provide full stack security level checking. This setting is compatible with more recent Microsoft* Visual Studio stack protection heuristics. This is the same as specifying /GS with no keyword.

Default

/GS- The compiler does not detect buffer overruns.

Description

This option determines whether the compiler generates code that detects some buffer overruns that overwrite a function's return address, exception handler address, or certain types of parameters.

This option has been added for Microsoft compatibility.

Following Visual Studio 2008, the Microsoft implementation of option /GS became more extensive (for example, more routines are protected). The performance of some programs may be impacted by the newer heuristics. In such cases, you may see better performance if you specify /GS:partial.

For more details about option /GS, see the Microsoft documentation.

IDE Equivalent

None

Alternate Options

Alternate Options

None

init, Qinit

Lets you initialize a class of variables to zero or to various numeric exceptional values.

Syntax

Linux OS and macOS:

`-init=`*`keyword`* `[, `*`keyword`* `]`

Windows OS:

`/Qinit:`*`keyword`* `[, `*`keyword`* `]`

Arguments

`keyword` Specifies the initial value for a class of variables. Possible values are:

[no]arrays	Determines whether the compiler initializes variables that are arrays or scalars. Specifying arrays initializes variables that are arrays or scalars. Specifying noarrays or neither arrays or noarrays initializes only variables that are scalars. You must also specify at least one other keyword when you specify keyword noarrays.
huge or minus_huge	Determines both of the following: • whether the compiler initializes to the largest representable positive or negative real value all uninitialized variables of intrinsic type REAL or COMPLEX that are saved, local, automatic, or allocated variables • whether the compiler initializes to the largest representable positive or negative integer value all uninitialized variables of intrinsic type INTEGER that are saved, local, automatic, or allocated variables
infinity or minus_infinity	Determines whether the compiler initializes to positive or negative Infinity all uninitialized variables of intrinsic type REAL or COMPLEX that are saved, local, automatic, or allocated variables.
[no]snan	Determines whether the compiler initializes to signaling NaN all uninitialized variables of intrinsic type REAL or COMPLEX that are saved, local, automatic, or allocated variables.
tiny or minus_tiny	Determines whether the compiler initializes to the smallest representable positive or negative real value all uninitialized variables of intrinsic type REAL or COMPLEX that are saved, local, automatic, or allocated variables.
[no]zero	Determines whether the compiler initializes to zero all uninitialized variables of intrinsic type REAL, COMPLEX, INTEGER, or LOGICAL that are saved, local, automatic, or allocated variables. Option /Qinit:[no]zero replaces option /Qzero[-] (Windows*) , and option -init=[no]zero replaces option -[no]zero (Linux* and macOS*).

Default

OFF	No initializations are performed by default if you do not specify any of these options.

Description

This option lets you initialize a class of variables to zero or to one or more of the various numeric exceptional values positive or negative huge, positive or negative Infinity, signaling NaN, or positive or negative tiny.

If you only specify the keyword [minus_]huge, [minus_]infinity, snan, [minus_]tiny, or zero, option [Q]init affects only scalar variables. To apply an initialization to arrays as well, you must also specify the keyword arrays.

If you have specified an ALLOCATE statement and you specify one or more [Q]init keywords, the initializers are applied to the memory that has been allocated by the ALLOCATE statement.

Keywords are applied to the various numeric types in the following order:

- For REAL and COMPLEX variables, keywords [minus_]huge, [minus_]infinity, snan, [minus_]tiny, and zero initialize to the specified value.
- For INTEGER variables, keywords [minus_]huge and zero initialize to the specified value.
- For LOGICAL variables, keyword zero initializes to .FALSE..

The following classes of variables are initialized by the [Q]init option:

- Variables of intrinsic numeric type, that is, of type COMPLEX, INTEGER, LOGICAL, or REAL, of any KIND
- SAVEd scalar or array variables, not in the main program, that are not initialized in the source code
- Local scalars and arrays
- Module variables that are not initialized in the source code
- Automatic arrays
- Integers can be set to `zero`, `huge`, or `minus_huge`.
- In a COMPLEX variable, each of the real and imaginary parts is separately initialized as a REAL.

The following are general restrictions for this option:

- The keywords `[minus_]infinity`, `snan`, and `[minus_]tiny` only affect certain variables of REAL or COMPLEX type.
- You cannot initialize variables in equivalence groups to any of the numeric exceptional values.
- In an equivalence group, if no member of that equivalence group has an explicit initialization or a default initialization (in the case of a derived type), a variable in that equivalence group can be initialized to zero but not to any of the numeric exceptional values.
- Derived types, arrays of derived types, and their components will not be initialized.
- Dummy arguments including adjustable arrays will not be initialized.
- Variables in COMMON will not be initialized.

The following spellings all cause the same behavior, that is, they initialize certain numeric arrays and scalars to zero:

- `[Q]init zero [Q]init arrays`
- `[Q]init arrays [Q]init zero`
- `[Q]init zero, arrays`
- `[Q]init arrays, zero`

Combinations of keywords will override each other in a left-to-right fashion as follows:

- `zero` and `nozero` override each other.
- `snan` and `nosnan` override each other.
- `huge` and `minus_huge` override each other.
- `tiny` and `minus_tiny` override each other.
- `infinity`, `minus_infinity`, and `snan` will all override each other.

Because a REAL or COMPLEX variable can be initialized to `huge` or `minus_huge`, `infinity` or `minus_infinity`, `tiny` or `minus_tiny`, `snan`, or `zero`, these initializations are applied in the following order:

1. `snan`
2. `infinity` or `minus_infinity`
3. `tiny` or `minus_tiny`
4. `huge` or `minus_huge`
5. `zero`

Because an INTEGER variable can be initialized to `huge` or `minus_huge`, or `zero`, these initializations are applied in the following order:

1. `huge` or `minus_huge`
2. `zero`

For example, if the you specify [Q]init zero, minus_huge, snan when compiling the following program:

```
program test
real X
integer K
complex C
end
```

The variable X will be initialized with a signaling NaN (`snan`), variable K will be initialized to the integer value `minus_huge`, and the real and imaginary parts of variable C will be initialized to a signaling NaN (`snan`) in each.

If you specify `[Q]init snan`, the floating-point exception handling flags will be set to trap signaling NaN and halt so that when such a value is trapped at run-time, the Fortran library can catch the usage, display an error message about a possible uninitialized variable, display a traceback, and stop execution. You can use the debugger to determine where in your code this uninitialized variable is being referenced when execution stops.

Setting the option `[Q]init snan` implicitly sets the option `fpe 0`. A compile time warning will occur if you specify both option `fpe 3` and option `[Q]init snan` on the command line. In this case, `fpe 3` is ignored.

NOTE
If you build with optimization, the compiler may speculate floating-point operations, assuming the default floating-point environment in which floating-point exceptions are masked. When you add `[Q]init snan`, this speculation may result in exceptions, unrelated to uninitialized variables, that now get trapped. To avoid this, reduce the optimization level to `/O1` or `/Od` (Windows*), or `-O1` or `-O0` (Linux* and macOS*) when doing uninitialized variable detection.

If you wish to maintain optimization, you should add option `[Q]fp-speculation safe` to disable speculation when there is a possibility that the speculation may result in a floating-point exception.

NOTE
To avoid possible performance issues, you should only use `[Q]init` for debugging (for example, `[Q]init zero`) and checking for uninitialized variables (for example, `[Q]init snan`).

Use option `[Q]save` if you wish all variables to be specifically marked as SAVE.

IDE Equivalent

Visual Studio: **Data > Initialize Variables to Signaling NaN**

Data > Initialize Variables to Zero

Data > Initialize Arrays as well as Scalars

Eclipse: None

Xcode: **Data > Initialize Variables to Signaling NaN**

Data > Initialize Variables to Zero

Data > Initialize Arrays as well as Scalars

Alternate Options

None

Example

The following example shows how to initialize scalars of intrinsic type REAL and COMPLEX to signaling NaN, and scalars of intrinsic type INTEGER and LOGICAL to zero:

```
-init=snan,zero               ! Linux and macOS* systems
/Qinit:snan,zero              ! Windows systems
```

The following example shows how to initialize scalars and arrays of intrinsic type REAL and COMPLEX to signaling NaN, and scalars and arrays of intrinsic type INTEGER and LOGICAL to zero:

```
-init=zero -init=snan -init=arrays       ! Linux and macOS* systems
/Qinit:zero /Qinit:snan /Qinit:arrays    ! Windows systems
```

To see an example of how to use option `[Q]init` for detection of uninitialized floating-point variables at run-time, see the article titled *Detection of Uninitialized Floating-point Variables in Intel® Fortran*, which is located in https://software.intel.com/articles/detection-of-uninitialized-floating-point-variables-in-intel-fortran

Explicit-Shape Specifications for details on automatic arrays and adjustable arrays

HUGE

TINY

Data Representation Models

intconstant

Tells the compiler to use FORTRAN 77 semantics to determine the kind parameter for integer constants.

Syntax

Linux OS and macOS:

`-intconstant`

`-nointconstant`

Windows OS:

`/intconstant`

`/nointconstant`

Arguments

None

Default

`nointconstant` The compiler uses the Fortran default INTEGER type.

Description

This option tells the compiler to use FORTRAN 77 semantics to determine the kind parameter for integer constants.

With FORTRAN 77 semantics, the kind is determined by the value of the constant. All constants are kept internally by the compiler in the highest precision possible. For example, if you specify option `intconstant`, the compiler stores an integer constant of 14 internally as INTEGER(KIND=8) and converts the constant upon reference to the corresponding proper size. Fortran specifies that integer constants with no explicit KIND are kept internally in the default INTEGER kind (KIND=4 by default).

Note that the internal precision for floating-point constants is controlled by option fpconstant.

IDE Equivalent

Visual Studio: **Compatibility > Use F77 Integer Constants**

Eclipse: None

Xcode: **Compatibility > Use F77 Integer Constants**

Alternate Options

None

integer-size

Specifies the default KIND for integer and logical variables.

Syntax

Linux OS and macOS:

`-integer-size` *size*

Windows OS:

`/integer-size:`*size*

Arguments

size	Is the size for integer and logical variables. Possible values are: 16, 32, or 64.

Default

`integer-size 32`	Integer and logical variables are 4 bytes long (INTEGER(KIND=4) and LOGICAL(KIND=4)).

Description

This option specifies the default size (in bits) for integer and logical variables.

Option	Description
`integer-size 16`	Makes default integer and logical declarations, constants, functions, and intrinsics 2 bytes long. INTEGER and LOGICAL declarations are treated as (KIND=2). Integer and logical constants of unspecified KIND are evaluated in INTEGER (KIND=2) and LOGICAL(KIND=2)respectively.
`integer-size 32`	Makes default integer and logical declarations, constants, functions, and intrinsics 4 bytes long. INTEGER and LOGICAL declarations are treated as (KIND=4). Integer and logical constants of unspecified KIND are evaluated in INTEGER (KIND=4) and LOGICAL(KIND=4)respectively.
`integer-size 64`	Makes default integer and logical declarations, constants, functions, and intrinsics 8 bytes long. INTEGER and LOGICAL declarations are treated as (KIND=8). Integer and logical constants of unspecified KIND are evaluated in INTEGER (KIND=8) and LOGICAL(KIND=8)respectively.

IDE Equivalent

Visual Studio: **Data > Default Integer KIND**

Eclipse: None

Xcode: **Data > Default Integer KIND**

Alternate Options

`integer-size 16`
Linux and macOS*: `-i2`
Windows: `/4I2`

`integer-size 32`
Linux and macOS*: `-i4`
Windows: `/4I4`

`integer-size 64`
Linux and macOS*: `-i8`
Windows: `/4I8`

mcmodel

Tells the compiler to use a specific memory model to generate code and store data.

Architecture Restrictions

Only available on Intel® 64 architecture

Syntax

Linux OS:

`-mcmodel=`*`mem_model`*

macOS:

`None`

Windows OS:

`None`

Arguments

mem_model
Is the memory model to use. Possible values are:

`small`	Tells the compiler to restrict code and data to the first 2GB of address space. All accesses of code and data can be done with Instruction Pointer (IP)-relative addressing.
`medium`	Tells the compiler to restrict code to the first 2GB; it places no memory restriction on data. Accesses of code can be done with IP-relative addressing, but accesses of data must be done with absolute addressing.
`large`	Places no memory restriction on code or data. All accesses of code and data must be done with absolute addressing.

Default

`-mcmodel=small`
On systems using Intel® 64 architecture, the compiler restricts code and data to the first 2GB of address space. Instruction Pointer (IP)-relative addressing can be used to access code and data.

Description

This option tells the compiler to use a specific memory model to generate code and store data. It can affect code size and performance. If your program has COMMON blocks and local data with a total size smaller than 2GB, `-mcmodel=small` is sufficient. COMMONs larger than 2GB require`-mcmodel=medium` or `-mcmodel=large`. Allocation of memory larger than 2GB can be done with any setting of `-mcmodel`.

IP-relative addressing requires only 32 bits, whereas absolute addressing requires 64-bits. IP-relative addressing is somewhat faster. So, the `small` memory model has the least impact on performance.

> **NOTE**
> When you specify option `-mcmodel=medium` or `-mcmodel=large`, it sets option `-shared-intel`. This ensures that the correct dynamic versions of the Intel run-time libraries are used.
>
> If you specify option `-static-intel` while `-mcmodel=medium` or `-mcmodel=large` is set, an error will be displayed.

IDE Equivalent

None

Alternate Options

None

Example

The following example shows how to compile using `-mcmodel`:

```
ifort -shared-intel -mcmodel=medium -o  prog prog.f
```

`shared-intel` compiler option
`fpic` compiler option

mdynamic-no-pic

Generates code that is not position-independent but has position-independent external references.

Syntax

Linux OS:

`None`

macOS:

`-mdynamic-no-pic`

Windows OS:

`None`

Arguments

None

Default

OFF All references are generated as position independent.

Description

This option generates code that is not position-independent but has position-independent external references.

The generated code is suitable for building executables, but it is not suitable for building shared libraries.

This option may reduce code size and produce more efficient code. It overrides the `-fpic` compiler option.

IDE Equivalent

None

Alternate Options

None

`fpic` compiler option

no-bss-init, Qnobss-init

Tells the compiler to place in the DATA section any uninitialized variables and explicitly zero-initialized variables.

Syntax

Linux OS and macOS:

`-no-bss-init`

Windows OS:

`/Qnobss-init`

Arguments

None

Default

OFF Uninitialized variables and explicitly zero-initialized variables are placed in the BSS section.

Description

This option tells the compiler to place in the DATA section any uninitialized variables and explicitly zero-initialized variables.

IDE Equivalent

None

Alternate Options

None

Qsfalign

Specifies stack alignment for functions.

Architecture Restrictions

Only available on IA-32 architecture

Syntax

Linux OS:

None

macOS:

None

Windows OS:

/Qsfalign[*n*]

Arguments

n Is the byte size of aligned variables. Possible values are:

8	Specifies that alignment should occur for functions with 8-byte aligned variables. At this setting the compiler aligns the stack to 16 bytes if there is any 16-byte or 8-byte data on the stack. For 8-byte data, the compiler only aligns the stack if the alignment will produce a performance advantage.
16	Specifies that alignment should occur for functions with 16-byte aligned variables. At this setting, the compiler only aligns the stack for 16-byte data. No attempt is made to align for 8-byte data.

Default

/Qsfalign8 Alignment occurs for functions with 8-byte aligned variables.

Description

This option specifies stack alignment for functions. It lets you disable the normal optimization that aligns a stack for 8-byte data.

If you do not specify *n*, stack alignment occurs for all functions. If you specify /Qsfalign-, no stack alignment occurs for any function.

IDE Equivalent

None

Alternate Options

None

real-size

Specifies the default KIND for real and complex declarations, constants, functions, and intrinsics.

Syntax

Linux OS and macOS:

`-real-size size`

Windows OS:

`/real-size:size`

Arguments

size	Is the size for real and complex declarations, constants, functions, and intrinsics. Possible values are: 32, 64, or 128.

Default

`real-size 32`	Default real and complex declarations, constants, functions, and intrinsics are 4 bytes long (REAL(KIND=4) and COMPLEX(KIND=4)).

Description

This option specifies the default size (in bits) for real and complex declarations, constants, functions, and intrinsics.

Option	Description
`real-size 32`	Makes default real and complex declarations, constants, functions, and intrinsics 4 bytes long. REAL declarations are treated as single precision REAL (REAL(KIND=4)) and COMPLEX declarations are treated as COMPLEX (COMPLEX(KIND=4)). Real and complex constants of unspecified KIND are evaluated in single precision (KIND=4).
`real-size 64`	Makes default real and complex declarations, constants, functions, and intrinsics 8 bytes long. REAL declarations are treated as DOUBLE PRECISION (REAL(KIND=8)) and COMPLEX declarations are treated as DOUBLE COMPLEX (COMPLEX(KIND=8)). Real and complex constants of unspecified KIND are evaluated in double precision (KIND=8).
`real-size 128`	Makes default real and complex declarations, constants, functions, and intrinsics 16 bytes long. REAL declarations are treated as extended precision REAL (REAL(KIND=16)); COMPLEX and DOUBLE COMPLEX declarations are treated as extended precision COMPLEX (COMPLEX(KIND=16)). Real and complex constants of unspecified KIND are evaluated in extended precision (KIND=16).

These compiler options can affect the result type of intrinsic procedures, such as CMPLX, FLOAT, REAL, SNGL, and AIMAG, which normally produce single-precision REAL or COMPLEX results. To prevent this effect, you must explicitly declare the kind type for arguments of such intrinsic procedures.

For example, if `real-size 64` is specified, the CMPLX intrinsic will produce a result of type DOUBLE COMPLEX (COMPLEX(KIND=8)). To prevent this, you must explicitly declare any real argument to be REAL(KIND=4), and any complex argument to be COMPLEX(KIND=4).

IDE Equivalent

Visual Studio: **Data > Default Real KIND**

Eclipse: None

Xcode: **Data > Default Real KIND**

Alternate Options

`real-size 64`
Linux and macOS*: `-r8`, `-autodouble`
Windows: `/4R8`, `/Qautodouble`

`real-size 128`
Linux and macOS*: `-r16`
Windows: `/4R16`

save, Qsave

Causes variables to be placed in static memory.

Syntax

Linux OS and macOS:

`-save`

Windows OS:

`/Qsave`

Arguments

None

Default

`-auto-scalar` or `/Qauto-scalar`
Scalar variables of intrinsic types INTEGER, REAL, COMPLEX, and LOGICAL are allocated to the run-time stack. Note that the default changes to `auto` if one of the following options are specified:

- `recursive`
- `[q or Q]openmp`

Description

This option saves all variables in static allocation except local variables within a recursive routine and variables declared as AUTOMATIC.

If you want all local, non-SAVEd variables to be allocated to the run-time stack, specify option `automatic`.

IDE Equivalent

Visual Studio: **Data > Local Variable Storage**

Eclipse: None

Xcode: **Data > Local Variable Storage**

Alternate Options

Linux and macOS*: `-noauto`

Windows: `/noauto`, `/4Na`

See Also

`auto` compiler option
`auto_scalar` compiler option

zero, Qzero

Initializes to zero variables of intrinsic type INTEGER, REAL, COMPLEX, or LOGICAL that are not yet initialized. This is a deprecated option. The replacement option is /Qinit:[no]zero or -init=[no]zero.

Syntax

Linux OS and macOS:

`-zero`

`-nozero`

Windows OS:

`/Qzero`

`/Qzero-`

Arguments

None

Default

`-nozero` or `/Qzero-` Variables are not initialized to zero.

Description

This option initializes to zero variables of intrinsic type INTEGER, REAL, COMPLEX, or LOGICAL that are not yet initialized.

Use option `[Q]save` on the command line to make all local variables specifically marked as SAVE.

IDE Equivalent

None

Alternate Options

None

See Also

`init, Qinit` compiler option (see setting zero)

`save` compiler option

Compiler Diagnostic Options

diag, Qdiag

Controls the display of diagnostic information during compilation.

Syntax

Linux OS and macOS:

`-diag-`*`type=diag-list`*

Windows OS:

`/Qdiag-`*`type`*`:`*`diag-list`*

Arguments

type

Is an action to perform on diagnostics. Possible values are:

`enable`	Enables a diagnostic message or a group of messages. If you specify `-diag-enable=all` (Linux* and macOS*) or `/Qdiag-enable:all` (Windows*), all diagnostic messages shown in *diag-list* are enabled.
`disable`	Disables a diagnostic message or a group of messages. If you specify `-diag-disable=all` (Linux* and macOS*) or `/Qdiag-disable:all` (Windows*), all diagnostic messages shown in *diag-list* are disabled.
`error`	Tells the compiler to change diagnostics to errors.
`warning`	Tells the compiler to change diagnostics to warnings.
`remark`	Tells the compiler to change diagnostics to remarks (comments).

diag-list

Is a diagnostic group or ID value. Possible values are:

`driver`	Specifies diagnostic messages issued by the compiler driver.
`vec`	Specifies diagnostic messages issued by the vectorizer.
`par`	Specifies diagnostic messages issued by the auto-parallelizer (parallel optimizer).
`openmp`	Specifies diagnostic messages issued by the OpenMP* parallelizer.
`warn`	Specifies diagnostic messages that have a "warning" severity level.
`error`	Specifies diagnostic messages that have an "error" severity level.
`remark`	Specifies diagnostic messages that are remarks or comments.
`cpu-dispatch`	Specifies the CPU dispatch remarks for diagnostic messages. These remarks are enabled by default.

`id[,id,...]`	Specifies the ID number of one or more messages. If you specify more than one message number, they must be separated by commas. There can be no intervening white space between each `id`.
`tag[,tag,...]`	Specifies the mnemonic name of one or more messages. If you specify more than one mnemonic name, they must be separated by commas. There can be no intervening white space between each `tag`.

The diagnostic messages generated can be affected by certain options, such as `[Q]x`, `/arch` (Windows) or `-m` (Linux and macOS*).

Default

OFF	The compiler issues certain diagnostic messages by default.

Description

This option controls the display of diagnostic information during compilation. Diagnostic messages are output to stderr unless the `[Q]diag-file` option is specified.

NOTE
The [Q]diag options do not control diagnostics emitted at run-time. For more information about run-time errors and diagnostics, see Handling Run-Time Errors.

To control the diagnostic information reported by the vectorizer, use options `[q or Q]opt-report` and `[q or Q]opt-report-phase`, phase `vec`.

To control the diagnostic information reported by the auto-parallelizer, use options `[q or Q]opt-report` and `[q or Q]opt-report-phase`, phase `par`.

IDE Equivalent

Visual Studio: **Diagnostics > Disable Specific Diagnostics**

Eclipse: None

Xcode: **Diagnostics > Disable Specific Diagnostics**

Alternate Options

enable vec	Linux and macOS*: `-qopt-report`; `-qopt-report -qopt-report-phase=vec` Windows: `/Qopt-report`; `/Qopt-report /Qopt-report-phase:vec`
disable vec	Linux and macOS*: `-qopt-report=0 -qopt-report-phase=vec` Windows: `/Qopt-report:0 /Qopt-report-phase:vec`
enable par	Linux and macOS*: `-qopt-report`; `-qopt-report -qopt-report-phase=par`

	Windows: `/Qopt-report`; `/Qopt-report /Qopt-report-phase:par`
disable par	Linux and macOS*: `-qopt-report=0 -qopt-report-phase=par` Windows: `/Qopt-report:0 /Qopt-report-phase:par`

Example

The following example shows how to enable diagnostic IDs 117, 230 and 450:

```
-diag-enable=117,230,450     ! Linux and macOS* systems
/Qdiag-enable:117,230,450    ! Windows systems
```

The following example shows how to change vectorizer diagnostic messages to warnings:

```
-diag-enable=vec -diag-warning=vec      ! Linux and macOS* systems
/Qdiag-enable:vec /Qdiag-warning:vec    ! Windows systems
```

Note that you need to enable the vectorizer diagnostics before you can change them to warnings.

The following example shows how to disable all auto-parallelizer diagnostic messages:

```
-diag-disable=par     ! Linux and macOS* systems
/Qdiag-disable:par    ! Windows systems
```

The following example shows how to change all diagnostic warnings and remarks to errors:

```
-diag-error=warn,remark    ! Linux and macOS* systems
/Qdiag-error:warn,remark   ! Windows systems
```

The following example shows how to get a list of *only* vectorization diagnostics:

```
-diag-dump -diag-disable=all -diag-enable=vec        ! Linux and macOS* systems
/Qdiag-dump /Qdiag-disable:all /Qdiag-enable:vec     ! Windows systems
```

See Also

`diag-dump, Qdiag-dump` compiler option
`diag-id-numbers, Qdiag-id-numbers` compiler option
`diag-file, Qdiag-file` compiler option
`qopt-report, Qopt-report` compiler option
`x, Qx` compiler option

diag-dump, Qdiag-dump

Tells the compiler to print all enabled diagnostic messages.

Syntax

Linux OS and macOS:

`-diag-dump`

Windows OS:

`/Qdiag-dump`

Arguments

None

Default

OFF The compiler issues certain diagnostic messages by default.

Description

This option tells the compiler to print all enabled diagnostic messages. The diagnostic messages are output to `stdout`.

This option prints the enabled diagnostics from all possible diagnostics that the compiler can issue, including any default diagnostics.

If *diag-list* is specified for the `[Q]diag-enable` option, the print out will include the *diag-list* diagnostics.

IDE Equivalent

None

Alternate Options

None

Example

The following example adds vectorizer diagnostic messages to the printout of default diagnostics:

```
-diag-enable vec -diag-dump          ! Linux and macOS* systems
/Qdiag-enable:vec /Qdiag-dump        ! Windows systems
```

See Also

`diag, Qdiag` compiler option

diag-error-limit, Qdiag-error-limit

Specifies the maximum number of errors allowed before compilation stops.

Syntax

Linux OS and macOS:

`-diag-error-limit=`*n*

`-no-diag-error-limit`

Windows OS:

`/Qdiag-error-limit:`*n*

`/Qdiag-error-limit-`

Arguments

n	Is the maximum number of error-level or fatal-level compiler errors allowed.

Default

30	A maximum of 30 error-level and fatal-level messages are allowed.

Description

This option specifies the maximum number of errors allowed before compilation stops. It indicates the maximum number of error-level or fatal-level compiler errors allowed for a file specified on the command line.

If you specify the negative form of the `[Q]diag-error-limit` option on the command line, there is no limit on the number of errors that are allowed.

If the maximum number of errors is reached, a warning message is issued and the next file (if any) on the command line is compiled.

IDE Equivalent

Visual Studio: **Diagnostics > Error Limit**

Eclipse: None

Xcode: **Diagnostics > Error Limit**

Alternate Options

Linux and macOS*: `-error-limit` and `-noerror-limit`

Windows: `/error-limit` and `/noerror-limit`

diag-file, Qdiag-file

Causes the results of diagnostic analysis to be output to a file.

Syntax

Linux OS:

`-diag-file[=`*`filename`*`]`

macOS:

`None`

Windows OS:

`/Qdiag-file[:`*`filename`*`]`

Arguments

filename	Is the name of the file for output.

Default

OFF	Diagnostic messages are output to stderr.

Description

This option causes the results of diagnostic analysis to be output to a file. The file is placed in the current working directory.

You can include a file extension in *filename*. For example, if *file.txt* is specified, the name of the output file is *file.txt*. If you do not provide a file extension, the name of the file is *filename.diag*.

If *filename* is not specified, the name of the file is *name-of-the-first-source-file.diag*. This is also the name of the file if the name specified for file conflicts with a source file name provided in the command line.

NOTE
If you specify the `[Q]diag-file` option and you also specify the `[Q]diag-file-append` option, the last option specified on the command line takes precedence.

IDE Equivalent

Visual Studio: **Diagnostics > Diagnostics File**

Eclipse: None

Xcode: **Diagnostics > Diagnostics File**

Alternate Options

None

Example

The following example shows how to cause diagnostic analysis to be output to a file named *my_diagnostics.diag*:

```
-diag-file=my_diagnostics       ! Linux systems
/Qdiag-file:my_diagnostics      ! Windows systems
```

See Also

`diag-file-append, Qdiag-file-append` compiler option

diag-file-append, Qdiag-file-append

Causes the results of diagnostic analysis to be appended to a file.

Syntax

Linux OS:

`-diag-file-append[=`*filename*`]`

macOS:

`None`

Windows OS:

`/Qdiag-file-append[:`*filename*`]`

Arguments

filename Is the name of the file to be appended to. It can include a path.

Default

OFF Diagnostic messages are output to `stderr`.

Description

This option causes the results of diagnostic analysis to be appended to a file. If you do not specify a path, the driver will look for *filename* in the current working directory.

If *filename* is not found, then a new file with that name is created in the current working directory. If the name specified for file conflicts with a source file name provided in the command line, the name of the file is *name-of-the-first-source-file.diag*.

NOTE
If you specify the `[Q]diag-file-append` option and you also specify the `[Q]diag-file` option, the last option specified on the command line takes precedence.

IDE Equivalent

None

Alternate Options

None

Example

The following example shows how to cause diagnostic analysis to be appended to a file named *my_diagnostics.txt*:

```
-diag-file-append=my_diagnostics.txt       ! Linux systems
/Qdiag-file-append:my_diagnostics.txt      ! Windows systems
```

See Also

`diag-file, Qdiag-file` compiler option

diag-id-numbers, Qdiag-id-numbers

Determines whether the compiler displays diagnostic messages by using their ID number values.

Syntax

Linux OS and macOS:

`-diag-id-numbers`

`-no-diag-id-numbers`

Windows OS:

`/Qdiag-id-numbers`

`/Qdiag-id-numbers-`

Arguments

None

Default

`-diag-id-numbers` or `/Qdiag-id-numbers`	The compiler displays diagnostic messages by using their ID number values.

Description

This option determines whether the compiler displays diagnostic messages by using their ID number values. If you specify the negative form of the `[Q]diag-id-numbers` option, mnemonic names are output for driver diagnostics only.

IDE Equivalent

None

Alternate Options

None

See Also

`diag, Qdiag` compiler option

diag-once, Qdiag-once

Tells the compiler to issue one or more diagnostic messages only once.

Syntax

Linux OS and macOS:

`-diag-once`*`id`*`[,`*`id`*`,...]`

Windows OS:

`/Qdiag-once:`*`id`*`[,`*`id`*`,...]`

Arguments

id	Is the ID number of the diagnostic message. If you specify more than one message number, they must be separated by commas. There can be no intervening white space between each *id*.

Default

OFF	The compiler issues certain diagnostic messages by default.

Description

This option tells the compiler to issue one or more diagnostic messages only once.

IDE Equivalent

None

Alternate Options

None

gen-interfaces

Tells the compiler to generate an interface block for each routine in a source file.

Syntax

Linux OS and macOS:

`-gen-interfaces [[`*`no`*`]`*`source`*`]`

`-nogen-interfaces`

Windows OS:

`/gen-interfaces[:[`*`no`*`]`*`source`*`]`

`/nogen-interfaces`

Arguments

None

Default

`nogen-interfaces` The compiler does not generate interface blocks for routines in a source file.

Description

This option tells the compiler to generate an interface block for each routine (that is, for each SUBROUTINE and FUNCTION statement) defined in the source file. The compiler generates two files for each routine, a .mod file and a .f90 file, and places them in the current directory or in the directory specified by the include (`-I`) or `-module` option. The .f90 file is the text of the interface block; the .mod file is the interface block compiled into binary form. The .f90 file is for reference only and may not completely represent the generated interface used by the compiler.

If `source` is specified, the compiler creates the *procedure-name*__GENmod.f90 as well as the *procedure-name*__GENmod.mod files. If `nosource` is specified, the compiler creates the *procedure-name*__GENmod.mod but not the *procedure-name*__GENmod.f90 files. If neither is specified, it is the same as specifying setting `source` for the `gen-interfaces` option.

On Windows* systems, for a Debug configuration in a Visual Studio project, the default is /warn:interfaces.

IDE Equivalent

Visual Studio: None

Eclipse: None

Xcode: **Diagnostics > Generate Interface Blocks**

Alternate Options

None

traceback

Tells the compiler to generate extra information in the object file to provide source file traceback information when a severe error occurs at run time.

Syntax

Linux OS and macOS:

`-traceback`

`-notraceback`

Windows OS:

`/traceback`

`/notraceback`

Arguments

None

Default

`notraceback` No extra information is generated in the object file to produce traceback information.

Description

This option tells the compiler to generate extra information in the object file to provide source file traceback information when a severe error occurs at run time.

When the severe error occurs, source file, routine name, and line number correlation information is displayed along with call stack hexadecimal addresses (program counter trace).

Note that when a severe error occurs, advanced users can also locate the cause of the error using a map file and the hexadecimal addresses of the stack displayed when the error occurs.

This option increases the size of the executable program, but has no impact on run-time execution speeds.

It functions independently of the debug option.

On Windows* systems, `traceback` sets the `/Oy-` option, which forces the compiler to use EBP as the stack frame pointer.

On Windows* systems, the linker places the traceback information in the executable image, in a section named ".trace". To see which sections are in an image, use the command:

```
link -dump -summary your_app_name.exe
```

To see more detailed information, use the command:

```
link -dump -headers your_app_name.exe
```

On Windows* systems, when requesting traceback, you must set Enable Incremental Linking in the VS .NET* IDE Linker Options to No. You must also set Omit Frame Pointers (the `/Oy` option) in the Optimization Options to "No."

On Linux* systems, to display the section headers in the image (including the header for the .trace section, if any), use the command:

```
objdump -h your_app_name.exe
```

On macOS* systems, to display the section headers in the image, use the command:

```
otool -l your_app_name.exe
```

IDE Equivalent

Visual Studio: **Run-time > Generate Traceback Information**

Eclipse: None

Xcode: **Run-time > Generate Traceback Information**

Alternate Options

None

warn

Specifies diagnostic messages to be issued by the compiler.

Syntax

Linux OS and macOS:

`-warn [keyword[, keyword...]]`

`-nowarn`

Windows OS:

`/warn[:keyword[, keyword...]]`

`/nowarn`

Arguments

keyword Specifies the diagnostic messages to be issued. Possible values are:

`none`	Disables all warning messages.
`[no]alignments`	Determines whether warnings occur for data that is not naturally aligned.
`[no]declarations`	Determines whether warnings occur for any undeclared names.
`[no]errors`	Determines whether warnings are changed to errors.
`[no]externals`	Determines whether warnings occur for any dummy procedures or procedure calls that have no explicit interface or have not been declared external.
`[no]general`	Determines whether warning messages and informational messages are issued by the compiler.
`[no]ignore_loc`	Determines whether warnings occur when %LOC is stripped from an actual argument.
`[no]interfaces`	Determines whether the compiler checks the interfaces of all SUBROUTINEs called and FUNCTIONs invoked in your compilation against an external set of interface blocks.
`[no]shape`	Determines whether array conformance violations are diagnosed with errors or warnings when used with the `check shape` option.
`[no]stderrors`	Determines whether warnings about Fortran standard violations are changed to errors.
`[no]truncated_source`	Determines whether warnings occur when source exceeds the maximum column width in fixed-format files.
`[no]uncalled`	Determines whether warnings occur when a statement function is never called
`[no]unused`	Determines whether warnings occur for declared variables that are never used.
`[no]usage`	Determines whether warnings occur for questionable programming practices.
`all`	Enables all warning messages except errors and stderrors.

Default

`alignments`	Warnings are issued about data that is not naturally aligned.
`general`	All information-level and warning-level messages are enabled.
`nodeclarations`	No warnings are issued for undeclared names.
`noerrors`	Warning-level messages are not changed to error-level messages.

`noexternals`	No warnings are issued when a dummy procedure or external procedure does not have an explicit interface and has not be declared external.
`noignore_loc`	No warnings are issued when %LOC is stripped from an argument.
`nointerfaces`	The compiler does not check interfaces of SUBROUTINEs called and FUNCTIONs invoked in your compilation against an external set of interface blocks.
`noshape`	Array conformance violations are issued as errors if the `check shape` option is specified.
`nostderrors`	Warning-level messages about Fortran standards violations are not changed to error-level messages.
`notruncated_source`	No warnings are issued when source exceeds the maximum column width in fixed-format files.
`nouncalled`	No warnings are issued when a statement function is not called.
`nounused`	No warnings are issued for variables that are declared but never used.
`usage`	Warnings are issued for questionable programming practices.

Description

This option specifies the diagnostic messages to be issued by the compiler.

Option	Description
`warn none`	Disables all warning messages. This is the same as specifying `nowarn`.
`warn noalignments`	Disables warnings about data that is not naturally aligned.
`warn declarations`	Enables warnings about any undeclared names. The compiler will use the default implicit data typing rules for such undeclared names. The IMPLICIT and IMPLICIT NONE statements override this option.
`warn errors`	Tells the compiler to change all warning-level messages to error-level messages; this includes warnings about Fortran standards violations.
`warn externals`	Enables warnings about dummy procedures and external procedures that do not have explicit interfaces and have not been declared with the EXTERNAL attribute.
`warn nogeneral`	Disables all informational-level and warning-level diagnostic messages.
`warn ignore_loc`	Enables warnings when %LOC is stripped from an actual argument.
`warn interfaces`	Tells the compiler to check the interfaces of all SUBROUTINEs called and FUNCTIONs invoked in your compilation against a set of interface blocks stored separately from the source being compiled. The compiler generates a compile-time message if the interface used to invoke a routine does not match the interface defined in a .mod file external to the source (that is, in a .mod generated by option `gen-interfaces` as opposed to a .mod file USEd in the source). The compiler looks for these .mods in the current directory or in the directory specified by the include (`-I`) or `-module` option. If interface mismatches occur, some will result in a compile-time error, others will only generate a warning.

Option	Description
	By default, `warn interfaces` turns on option `gen-interfaces`. You can turn off that option by explicitly specifying option `/gen-interfaces-` (Windows*) or `-no-gen-interfaces` (Linux* and macOS*).
`warn shape`	If the `check shape` option is specified, array conformance violations are issued as warnings rather than as errors.
`warn stderrors`	Tells the compiler to change all warning-level messages about Fortran standards violations to error-level messages. This option sets the stand option.
`warn truncated_source`	Enables warnings when a source line exceeds the maximum column width in fixed-format source files. The maximum column width for fixed-format files is 72, 80, or 132, depending on the setting of the `extend-source` option. The `warn truncated_source` option has no effect on truncation; lines that exceed the maximum column width are always truncated. This option does not apply to free-format source files.
`warn uncalled`	Enables warnings when a statement function is never called.
`warn unused`	Enables warnings for variables that are declared but never used.
`warn nousage`	Disables warnings about questionable programming practices. Questionable programming practices, although allowed, often are the result of programming errors; for example: a continued character or Hollerith literal whose first part ends before the statement field and appears to end with trailing spaces. Note that the `/pad-source` option can prevent this error.
`warn all`	This is the same as specifying `warn`. This option does not set options `warn errors` or `warn stderrors`. To enable all the additional checking to be performed and force the severity of the diagnostic messages to be severe enough to not generate an object file, specify `warn allwarn errors` or `warn allwarn stderrors`. On Windows systems: In the Property Pages, **Custom** means that diagnostics will be specified on an individual basis.

IDE Equivalent

Visual Studio: **General > Compile Time Diagnostics** (`/warn:all, /warn:none`)

Diagnostics > Treat Warnings as Errors (`/warn:[no]errors`)

Diagnostics > Treat Fortran Standard Warnings as Errors (`/warn:[no]stderrors`)

Diagnostics > Language Usage Warnings > Compile Time Diagnostics (`/warn:all, /warn:none`)

Diagnostics > Warn for Undeclared Symbols (`/warn:[no]declarations`)

Diagnostics > Warn for Undeclared Externals (`/warn:[no]externals`)

Diagnostics > Warn for Unused Variables (`/warn:[no]unused`)

Diagnostics > Warn When Removing %LOC (`/warn:[no]ignore_loc`)

Diagnostics > Warn When Truncating Source Line (`/warn:[no]truncated_source`)

Diagnostics > Warn for Unaligned Data (`/warn:[no]alignments`)

Diagnostics > Warn for Uncalled Statement Function (`/warn:[no]uncalled`)

Diagnostics > Warn for Array Conformance Violations (`/warn:shape`)

Diagnostics > Suppress Usage Messages (`/warn:[no]usage`)

Diagnostics > Check Routine Interfaces (`/warn:[no]interfaces`)

Eclipse: None

Xcode: **General > Compile Time Diagnostics** (`-warn all, -warn none`)

Diagnostics > Warn For Unaligned Data (`-warn [no]alignments`)

Diagnostics > Warn For Undeclared Symbols (`-warn [no]declarations`)

Diagnostics > Warn for Undeclared Externals (`-warn [no]externals`)

Diagnostics > Treat Warnings as Errors (`-warn error`)

Diagnostics > Warn When Removing %LOC (`-warn [no]ignore_loc`)

Diagnostics > Check Routine Interfaces (`-warn [no]interfaces`)

Diagnostics > Treat Fortran Standard Warnings As Errors (`-warn [no]stderrors`)

Diagnostics > Warn When Truncating Source Line (`-warn [no]truncated_source`)

Diagnostics > Warn For Uncalled Routine (`-warn [no]uncalled`)

Diagnostics > Warn For Unused Variables (`-warn [no]unused`)

Diagnostics > Warn for Array Conformance Violations (`-warn [no]shape`)

Diagnostics > Suppress Usage Messages (`-warn [no]usage`)

Alternate Options

`warn none`
Linux and macOS*: `-nowarn`, `-w`, `-W0`, `-warn nogeneral`
Windows: `/nowarn`,`/w`, `/W0`, `/warn:nogeneral`

`warn declarations`
Linux and macOS*: `-implicitnone`, `-u`
Windows: `/4Yd`

`warn nodeclarations`
Linux and macOS*: None
Windows: `/4Nd`

`warn general`
Linux and macOS*: `-W1`
Windows: `/W1`

`warn nogeneral`
Linux and macOS*: `-W0`, `-w`, `-nowarn`, `-warn none`
Windows: `/W0`, `/w`, `/nowarn`, `/warn:none`

`warn stderrors`
Linux and macOS*: `-e90`, `-e95`, `-e03`, `-e08`, `-e18`
Windows: None

`warn all`
Linux and macOS*: `-warn`
Windows: `/warn` (this is a deprecated option)

WB

Turns a compile-time bounds check into a warning.

Syntax

Linux OS and macOS:

`-WB`

Windows OS:

`/WB`

Arguments

None

Default

OFF Compile-time bounds checks are errors.

Description

This option turns a compile-time bounds check into a warning.

IDE Equivalent

None

Alternate Options

None

Winline

Warns when a function that is declared as inline is not inlined.

Syntax

Linux OS and macOS:

`-Winline`

Windows OS:

`None`

Arguments

None

Default

OFF No warning is produced when a function that is declared as inline is not inlined.

Description

This option warns when a function that is declared as inline is not inlined.

To see diagnostic messages, including a message about why a particular function was not inlined, you should generate an optimization report by specifying option `-qopt-report=5`.

IDE Equivalent

None

Alternate Options

None

See Also

`qopt-report, Qopt-report` compiler option

Compatibility Options

f66

Tells the compiler to apply FORTRAN 66 semantics.

Syntax

Linux OS and macOS:

`-f66`

Windows OS:

`/f66`

Arguments

None

Default

OFF The compiler applies Fortran 2008 semantics.

Description

This option tells the compiler to apply FORTRAN 66 semantics when interpreting language features. This causes the following to occur:

- DO loops are always executed at least once
- FORTRAN 66 EXTERNAL statement syntax and semantics are allowed
- If the OPEN statement STATUS specifier is omitted, the default changes to STATUS='NEW' instead of STATUS='UNKNOWN'
- If the OPEN statement BLANK specifier is omitted, the default changes to BLANK='ZERO' instead of BLANK='NULL'

IDE Equivalent

Visual Studio: **Language > Enable FORTRAN 66 Semantics**

Eclipse: None

Xcode: **Language > Enable FORTRAN 66 Semantics**

Alternate Options

None

f77rtl

Tells the compiler to use the run-time behavior of FORTRAN 77.

Syntax

Linux OS and macOS:

`-f77rtl`

`-nof77rtl`

Windows OS:

`/f77rtl`

`/nof77rtl`

Arguments

None

Default

`nof77rtl` The compiler uses the run-time behavior of Intel® Fortran.

Description

This option tells the compiler to use the run-time behavior of FORTRAN 77.

Specifying this option controls the following run-time behavior:

- When the unit is not connected to a file, some INQUIRE specifiers will return different values:
  - NUMBER= returns 0
  - ACCESS= returns 'UNKNOWN'
  - BLANK= returns 'UNKNOWN'
  - FORM= returns 'UNKNOWN'
- PAD= defaults to 'NO' for formatted input.
- NAMELIST and list-directed input of character strings must be delimited by apostrophes or quotes.
- When processing NAMELIST input:
  - Column 1 of each record is skipped.
  - The '$' or '&' that appears prior to the group-name must appear in column 2 of the input record.

IDE Equivalent

Visual Studio: **Compatibility > Enable F77 Run-Time Compatibility**

Eclipse: None

Xcode: **Compatibility > Enable F77 Run-Time Compatibility**

Alternate Options

None

fpscomp

Controls whether certain aspects of the run-time system and semantic language features within the compiler are compatible with Intel® Fortran or Microsoft Fortran PowerStation.*

Syntax

Linux OS and macOS:

`-fpscomp [keyword[, keyword...]]`

`-nofpscomp`

Windows OS:

`/fpscomp[:keyword[, keyword...]]`

`/nofpscomp`

Arguments

keyword Specifies the compatibility that the compiler should follow. Possible values are:

`none`	Specifies that no options should be used for compatibility.
`[no]filesfromcmd`	Determines what compatibility is used when the OPEN statement FILE= specifier is blank.
`[no]general`	Determines what compatibility is used when semantics differences exist between Fortran PowerStation and Intel® Fortran.
`[no]iofformat`	Determines what compatibility is used for list-directed formatted and unformatted I/O.
`[no]libs`	Determines whether the portability library is passed to the linker.
`[no]ldio_spacing`	Determines whether a blank is inserted at run-time after a numeric value before a character value.
`[no]logicals`	Determines what compatibility is used for representation of LOGICAL values.
`all`	Specifies that all options should be used for compatibility.

Default

`fpscomp libs` The portability library is passed to the linker.

Description

This option controls whether certain aspects of the run-time system and semantic language features within the compiler are compatible with Intel Fortran or Microsoft* Fortran PowerStation.

If you experience problems when porting applications from Fortran PowerStation, specify `fpscomp` (or `fpscomp all`). When porting applications from Intel Fortran, use `fpscomp none` or `fpscomp libs` (the default).

Option	Description
`fpscomp none`	Specifies that no options should be used for compatibility with Fortran PowerStation. This is the same as specifying `nofpscomp`. Option `fpscomp none` enables full Intel® Fortran compatibility. If you omit `fpscomp`, the default is `fpscomp libs`. You cannot use the `fpscomp` and `vms` options in the same command.
`fpscomp filesfromcmd`	Specifies Fortran PowerStation behavior when the OPEN statement FILE= specifier is blank (FILE=' '). It causes the following actions to be taken at run time:

Option	Description
	• The program reads a file name from the list of arguments (if any) in the command line that invoked the program. If any of the command-line arguments contain a null string (''), the program asks the user for the corresponding file name. Each additional OPEN statement with a blank FILE= specifier reads the next command-line argument. • If there are more nameless OPEN statements than command-line arguments, the program prompts for additional file names. • In a QuickWin application, a "File Select" dialog box appears to request file names. To prevent the run-time system from using the file name specified on the command line when the OPEN statement FILE specifier is omitted, specify `fpscomp nofilesfromcmd`. This allows the application of Intel Fortran defaults, such as the FORTn environment variable and the FORT. *n* file name (where *n* is the unit number). The `fpscomp filesfromcmd` option affects the following Fortran features: • The OPEN statement FILE specifier For example, assume a program OPENTEST contains the following statements: OPEN(UNIT = 2, FILE = ' ') OPEN(UNIT = 3, FILE = ' ') OPEN(UNIT = 4, FILE = ' ') The following command line assigns the file TEST.DAT to unit 2, prompts the user for a file name to associate with unit 3, then prompts again for a file name to associate with unit 4: opentest test.dat '' '' • Implicit file open statements such as the WRITE, READ, and ENDFILE statements Unopened files referred to in READ or WRITE statements are opened implicitly as if there had been an OPEN statement with a name specified as all blanks. The name is read from the command line.

`fpscomp general`	Specifies that Fortran PowerStation semantics should be used when a difference exists between Intel Fortran and Fortran PowerStation. The `fpscomp general` option affects the following Fortran features:
	
	• The BACKSPACE statement:
	
	  • It allows files opened with ACCESS='APPEND' to be used with the BACKSPACE statement.
	  • It allows files opened with ACCESS='DIRECT' to be used with the BACKSPACE statement.
	
	  Note: Allowing files that are not opened with sequential access (such as ACCESS='DIRECT') to be used with the BACKSPACE statement violates the Fortran 95 standard and may be removed in the future.
	• The READ statement:

Option	Description

- It causes a READ from a formatted file opened for direct access to read records that have the same record type format as Fortran PowerStation. This consists of accounting for the trailing Carriage Return/Line Feed pair (<CR><LF>) that is part of the record. It allows sequential reads from a formatted file opened for direct access.

  Note: Allowing files that are not opened with sequential access (such as ACCESS='DIRECT') to be used with the sequential READ statement violates the Fortran 95 standard and may be removed in the future.
- It allows the last record in a file opened with FORM='FORMATTED' and a record type of STREAM_LF or STREAM_CR that does not end with a proper record terminator (<line feed> or <carriage return>) to be read without producing an error.
- It allows sequential reads from an unformatted file opened for direct access.
- Note: Allowing files that are not opened with sequential access (such as ACCESS='DIRECT') to be read with the sequential READ statement violates the Fortran 95 standard and may be removed in the future.

- The INQUIRE statement:
  - The CARRIAGECONTROL specifier returns the value "UNDEFINED" instead of "UNKNOWN" when the carriage control is not known.
  - The NAME specifier returns the file name "UNKNOWN" instead of filling the file name with spaces when the file name is not known.
  - The SEQUENTIAL specifier returns the value "YES" instead of "NO" for a direct access formatted file.
  - The UNFORMATTED specifier returns the value "NO" instead of "UNKNOWN" when it is not known whether unformatted I/O can be performed to the file.

    Note: Returning the value "NO" instead of "UNKNOWN" for this specifier violates the Fortran 95 standard and may be removed in the future.
- The OPEN statement:
  - If a file is opened with an unspecified STATUS keyword value, and is not named (no FILE specifier), the file is opened as a scratch file.

    For example:

    OPEN (UNIT = 4)
  - In contrast, when fpscomp nogeneral is in effect with an unspecified STATUS value with no FILE specifier, the FORT*n* environment variable and the FORT.n file name are used (where *n* is the unit number).
  - If the STATUS value was not specified and if the name of the file is "USER", the file is marked for deletion when it is closed.
  - It allows a file to be opened with the APPEND and READONLY characteristics.
  - If the default for the CARRIAGECONTROL specifier is assumed, it gives "LIST" carriage control to direct access formatted files instead of "NONE".
  - If the default for the CARRIAGECONTROL specifier is assumed and the device type is a terminal file, the file is given the default carriage control value of "FORTRAN" instead of "LIST".
  - It gives an opened file the additional default of write sharing.
  - It gives the file a default block size of 1024 instead of 8192.
  - If the default for the MODE and ACTION specifier is assumed and there was an error opening the file, try opening the file as read only, then write only.

Option	Description

	• If a file that is being re-opened has a different file type than the current existing file, an error is returned.
	• It gives direct access formatted files the same record type as Fortran PowerStation. This means accounting for the trailing Carriage Return/Line Feed pair (<CR><LF>) that is part of the record.
	• The STOP statement: It writes the Fortran PowerStation output string and/or returns the same exit condition values.
	• The WRITE statement:
	  • Writing to formatted direct files
	  When writing to a formatted file opened for direct access, records are written in the same record type format as Fortran PowerStation. This consists of adding the trailing Carriage Return/Line Feed pair <CR><LF>) that is part of the record.
	  It ignores the CARRIAGECONTROL specifier setting when writing to a formatted direct access file.
	  • Interpreting Fortran carriage control characters
	  When interpreting Fortran carriage control characters during formatted I/O, carriage control sequences are written that are the same as Fortran PowerStation. This is true for the "Space, 0, 1 and + " characters.
	  • Performing non-advancing I/O to the terminal
	  When performing non-advancing I/O to the terminal, output is written in the same format as Fortran PowerStation.
	  • Interpreting the backslash (\) and dollar ($) edit descriptors
	  When interpreting backslash and dollar edit descriptors during formatted I/O, sequences are written the same as Fortran PowerStation.
	  • Performing sequential writes
	  It allows sequential writes from an unformatted file opened for direct access.
	  Note: Allowing files that are not opened with sequential access (such as ACCESS='DIRECT') to be read with the sequential WRITE statement violates the Fortran 95 standard and may be removed in the future.
	Specifying `fpscomp general` sets `fpscomp ldio_spacing`.

`fpscomp ioformat`	Specifies that Fortran PowerStation semantic conventions and record formats should be used for list-directed formatted and unformatted I/O. The `fpscomp ioformat` option affects the following Fortran features:
	• The WRITE statement:
	  • For formatted list-directed WRITE statements, formatted internal list-directed WRITE statements, and formatted namelist WRITE statements, the output line, field width values, and the list-directed data type semantics are determined according to the following sample for real constants (N below):
	  For 1 <= N < 10**7, use F15.6 for single precision or F24.15 for double.
	  For N < 1 or N >= 10**7, use E15.6E2 for single precision or E24.15E3 for double.
	  See the Fortran PowerStation documentation for more detailed information about the other data types affected.

Option	Description

- For unformatted WRITE statements, the unformatted file semantics are dictated according to the Fortran PowerStation documentation; these semantics are different from the Intel Fortran file format. See the Fortran PowerStation documentation for more detailed information.

  The following table summarizes the default output formats for list-directed output with the intrinsic data types:

Data Type	Output Format with fpscomp noioformat	Output Format with fpscomp ioformat
BYTE	I5	I12
LOGICAL (all)	L2	L2
INTEGER(1)	I5	I12
INTEGER(2)	I7	I12
INTEGER(4)	I12	I12
INTEGER(8)	I22	I22
REAL(4)	1PG15.7E2	1PG16.6E2
REAL(8)	1PG24.15E3	1PG25.15E3
COMPLEX(4)	'(',1PG14.7E2, ', ', 1PG14.7E2, ') '	'(',1PG16.6E2, ', ', 1PG16.6E2, ') '
COMPLEX(8)	'(',1PG23.15E3, ', ', 1PG23.15E3, ') '	'(',1PG25.15E3, ', ', 1PG25.15E3, ') '
CHARACTER	Aw	Aw

- The READ statement:
  - For formatted list-directed READ statements, formatted internal list-directed READ statements, and formatted namelist READ statements, the field width values and the list-directed semantics are dictated according to the following sample for real constants (N below):

    For 1 <= N < 10**7, use F15.6 for single precision or F24.15 for double.

    For N < 1 or N >= 10**7, use E15.6E2 for single precision or E24.15E3 for double.

    See the Fortran PowerStation documentation for more detailed information about the other data types affected.
  - For unformatted READ statements, the unformatted file semantics are dictated according to the Fortran PowerStation documentation; these semantics are different from the Intel Fortran file format. See the Fortran PowerStation documentation for more detailed information.

Option	Description
`fpscomp nolibs`	Prevents the portability library from being passed to the linker.
`fpscomp ldio_spacing`	Specifies that at run time a blank should not be inserted after a numeric value before a character value (undelimited character string). This representation is used by Intel Fortran releases before Version 8.0 and by Fortran PowerStation. If you specify `fpscomp general`, it sets `fpscomp ldio_spacing`.
`fpscomp logicals`	Specifies that integers with a non-zero value are treated as true, integers with a zero value are treated as false. The literal constant .TRUE. has an integer value of 1, and the literal constant .FALSE. has an integer value of 0. This representation is used by Intel Fortran releases before Version 8.0 and by Fortran PowerStation. The default is `fpscomp nologicals`, which specifies that odd integer values (low bit one) are treated as true and even integer values (low bit zero) are treated as false. The literal constant .TRUE. has an integer value of -1, and the literal constant .FALSE. has an integer value of 0. This representation is used by Compaq* Visual Fortran. The internal representation of LOGICAL values is not specified by the Fortran standard. Programs which use integer values in LOGICAL contexts, or which pass LOGICAL values to procedures written in other languages, are non-portable and may not execute correctly. Intel recommends that you avoid coding practices that depend on the internal representation of LOGICAL values. The `fpscomp logicals` option affects the results of all logical expressions and affects the return value for the following Fortran features: • The INQUIRE statement specifiers OPENED, IOFOCUS, EXISTS, and NAMED • The EOF intrinsic function • The BTEST intrinsic function • The lexical intrinsic functions LLT, LLE, LGT, and LGE
`fpscomp all`	Specifies that all options should be used for compatibility with Fortran PowerStation. This is the same as specifying `fpscomp` with no keyword. Option `fpscomp all` enables full compatibility with Fortran PowerStation.

IDE Equivalent

Visual Studio: **Compatibility > Use Filenames from Command Line** (`/fpscomp:filesfromcmd`)

Compatibility > Use PowerStation I/O Format (`/fpscomp:ioformat`)

Compatibility > Use PowerStation Portability Library (`/fpscomp:nolibs`)

Compatibility > Use PowerStation List-Directed I/O Spacing (`/fpscomp:ldio_spacing`)

Compatibility > Use PowerStation Logical Values (`/fpscomp:logicals`)

Compatibility > Use Other PowerStation Run-time Behavior (`/fpscomp:general`)

Eclipse: None

Xcode: None

Alternate Options

None

gcc-name

Lets you specify the name of the gcc compiler that should be used to set up the link-time environment, including the location of standard libraries.

Syntax

Linux OS:

`-gcc-name=`*`name`*

macOS:

`None`

Windows OS:

`None`

Arguments

name	Is the name of the gcc compiler to use. It can include the path where the gcc compiler is located.

Default

OFF	The compiler uses the PATH setting to find the gcc compiler and resolve environment settings.

Description

This option lets you specify the name of the gcc compiler that should be used to set up the link-time environment, including the location of standard libraries. If you do not specify a path, the compiler will search the PATH settings for the compiler name you provide.

This option is helpful when you are referencing a non-standard gcc installation, or you have multiple gcc installations on your system. The compiler will match gcc version values to the gcc compiler you specify.

The C++ equivalent to option `-gcc-name` is `-gxx-name`.

IDE Equivalent

None

Alternate Options

None

Example

If the following option is specified, the compiler looks for the gcc compiler named `foobar` in the PATH setting:

```
-gcc-name=foobar
```

If the following option is specified, the compiler looks for the gcc compiler named `foobar` in the path specified:

```
-gcc-name=/a/b/foobar
```

See Also

`gxx-name` compiler option

gxx-name

Lets you specify the name of the g++ compiler that should be used to set up the link-time environment, including the location of standard libraries.

Syntax

Linux OS:

`-gxx-name=`*`name`*

macOS:

`None`

Windows OS:

`None`

Arguments

name	Is the name of the g++ compiler to use. It can include the path where the g++ compiler is located.

Default

OFF	The compiler uses the PATH setting to find the g++ compiler and resolve environment settings.

Description

This option lets you specify the name of the g++ compiler that should be used to set up the link-time environment, including the location of standard libraries. If you do not specify a path, the compiler will search the PATH settings for the compiler name you provide.

This option is helpful if you have multiple gcc++ installations on your system. The compiler will match gcc++ version values to the gcc++ compiler you specify.

The C equivalent to option `-gxx-name` is `-gcc-name`.

NOTE
When compiling a C++ file with `icc`, g++ is used to get the environment.

IDE Equivalent

None

Alternate Options

None

Example

If the following option is specified, the compiler looks for the g++ compiler named `foobar` in the PATH setting:

```
-gxx-name=foobar
```

If the following option is specified, the compiler looks for the g++ compiler named `foobar` in the path specified:

```
-gxx-name=/a/b/foobar
```

`gcc-name` compiler option

Qvc

*Specifies compatibility with Microsoft*Visual C++* or Microsoft Visual Studio*.*

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/Qvc14.2`

`/Qvc14.1`

Arguments

None

Default

varies — When the compiler is installed, it detects which version of Visual Studio is on your system. `Qvc` defaults to the form of the option that is compatible with that version. When multiple versions of Visual Studio are installed, the compiler installation lets you select which version you want to use. In this case, `Qvc` defaults to the version you choose.

Description

This option specifies compatibility with Microsoft* Visual C++ or Microsoft* Visual Studio.

Option	Description
`/Qvc14.2`	Specifies compatibility with Microsoft* Visual Studio 2019.
`/Qvc14.1`	Specifies compatibility with Microsoft* Visual Studio 2017.

IDE Equivalent

None

Alternate Options

None

vms

Causes the run-time system to behave like HP Fortran on OpenVMS* Alpha systems and VAX* systems (VAX FORTRAN*).*

Syntax

Linux OS and macOS:

`-vms`

`-novms`

Windows OS:

`/vms`

`/novms`

Arguments

None

Default

`novms` The run-time system follows default Intel® Fortran behavior.

Description

This option causes the run-time system to behave like HP* Fortran on OpenVMS* Alpha systems and VAX* systems (VAX FORTRAN*).

It affects the following language features:

- Certain defaults

  In the absence of other options, `vms` sets the defaults as `check format` and `check output_conversion`.
- Alignment

  Option `vms` does not affect the alignment of fields in records or items in common blocks. For compatibility with HP Fortran on OpenVMS systems, use `align norecords` to pack fields of records on the next byte boundary.
- Carriage control default

  If option `vms` and option `ccdefault default` are specified, carriage control defaults to FORTRAN if the file is formatted and the unit is connected to a terminal.
- INCLUDE qualifiers

  `/LIST` and `/NOLIST` are recognized at the end of the file name in an INCLUDE statement at compile time. If the file name in the INCLUDE statement does not specify the complete path, the path used is the current directory. Note that if `vms` is not specified, the path used is the directory where the file that contains the INCLUDE statement resides.
- Quotation mark character

  A quotation mark (") character is recognized as starting an octal constant ("0..7) instead of a character literal ("...").
- Deleted records in relative files

  When a record in a relative file is deleted, the first byte of that record is set to a known character (currently '@'). Attempts to read that record later result in ATTACCNON errors. The rest of the record (the whole record, if `vms` is not specified) is set to nulls for unformatted files and spaces for formatted files.
- ENDFILE records

  When an ENDFILE is performed on a sequential unit, an actual 1-byte record containing a Ctrl/Z is written to the file. If `vms` is not specified, an internal ENDFILE flag is set and the file is truncated. The `vms` option does not affect ENDFILE on relative files: these files are truncated.

- Implied logical unit numbers

  The `vms` option enables Intel® Fortran to recognize certain environment variables at run time for ACCEPT, PRINT, and TYPE statements and for READ and WRITE statements that do not specify a unit number (such as READ (*,1000)).
- Treatment of blanks in input

  The `vms` option causes the defaults for the keyword BLANK in OPEN statements to become 'NULL' for an explicit OPEN and 'ZERO' for an implicit OPEN of an external or internal file.
- OPEN statement effects

  Carriage control defaults to FORTRAN if the file is formatted, and the unit is connected to a terminal. Otherwise, carriage control defaults to LIST. The `vms` option affects the record length for direct access and relative organization files. The buffer size is increased by 1 to accommodate the deleted record character.
- Reading deleted records and ENDFILE records

  The run-time direct access READ routine checks the first byte of the retrieved record. If this byte is '@' or NULL ("\0"), then an ATTACCNON error is returned. The run-time sequential access READ routine checks to see if the record it just read is one byte long and contains a Ctrl/Z. If this is true, it returns EOF.

IDE Equivalent

Visual Studio: **Compatibility > Enable VMS Compatibility**

Eclipse: None

Xcode: **Compatibility > Enable VMS Compatibility**

Linking or Linker Options

4Nportlib, 4Yportlib

Determines whether the compiler links to the library of portability routines.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/4Nportlib`

`/4Yportlib`

Arguments

None

Default

/4Yportlib	The library of portability routines is linked during compilation.

Description

Option /4Yportlib causes the compiler to link to the library of portability routines. This also includes Intel's functions for Microsoft* compatibility.

Option /4Nportlib prevents the compiler from linking to the library of portability routines.

IDE Equivalent

Visual Studio: **Libraries > Use Portlib Library**

Eclipse: None

Xcode: None

Alternate Options

None

Bdynamic

Enables dynamic linking of libraries at run time.

Syntax

Linux OS:

-Bdynamic

macOS:

None

Windows OS:

None

Arguments

None

Default

OFF	Limited dynamic linking occurs.

Description

This option enables dynamic linking of libraries at run time. Smaller executables are created than with static linking.

This option is placed in the linker command line corresponding to its location on the user command line. It controls the linking behavior of any library that is passed using the command line.

All libraries on the command line following option -Bdynamic are linked dynamically until the end of the command line or until a -Bstatic option is encountered. The -Bstatic option enables static linking of libraries.

IDE Equivalent

None

Alternate Options

None

See Also

`Bstatic` compiler option

Bstatic

Enables static linking of a user's library.

Syntax

Linux OS:

`-Bstatic`

macOS:

`None`

Windows OS:

`None`

Arguments

None

Default

OFF Default static linking occurs.

Description

This option enables static linking of a user's library.

This option is placed in the linker command line corresponding to its location on the user command line. It controls the linking behavior of any library that is passed using the command line.

All libraries on the command line following option `-Bstatic` are linked statically until the end of the command line or until a `-Bdynamic` option is encountered. The `-Bdynamic` option enables dynamic linking of libraries.

IDE Equivalent

None

Alternate Options

None

`Bdynamic` compiler option

Bsymbolic

Binds references to all global symbols in a program to the definitions within a user's shared library.

Syntax

Linux OS:

`-Bsymbolic`

macOS:

None

Windows OS:

None

Arguments

None

Default

OFF	When a program is linked to a shared library, it can override the definition within the shared library.

Description

This option binds references to all global symbols in a program to the definitions within a user's shared library.

This option is only meaningful on Executable Linkage Format (ELF) platforms that support shared libraries.

Caution
This option can have unintended side-effects of disabling symbol preemption in the shared library.

IDE Equivalent

None

Alternate Options

None

`Bsymbolic` compiler option

cxxlib

Determines whether the compiler links using the C++ run-time libraries provided by gcc.

Syntax

Linux OS and macOS:

`-cxxlib`

`-no-cxxlib`

Windows OS:

`None`

Arguments

None

Default

`-no-cxxlib`	The compiler uses the default run-time libraries and does not link to any additional C++ run-time libraries.

Description

This option determines whether the compiler links to the standard C++ run-time library (libstdc++). It is useful for building mixed Fortran/C++ applications.

Option `-cxxlib=`*dir* can be used with option `-gcc-name=`*name* to specify the location *`dir`*`/bin/`*`name`*.

IDE Equivalent

None

Alternate Options

None

`gcc-name` compiler option

dbglibs

Tells the linker to search for unresolved references in a debug run-time library.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/dbglibs`

`/nodbglibs`

Arguments

None

Default

`/nodbglibs` The linker does not search for unresolved references in a debug run-time library.

Description

This option tells the linker to search for unresolved references in a debug run-time library.

This option is processed by the compiler, which adds directives to the compiled object file that are processed by the linker.

The following table shows which options to specify for a debug run-time library:

Type of Library	Options Required	Alternate Option
Debug single-threaded	`/libs:static` `/dbglibs`	`/MLd` (this is a deprecated option)

Debug multithreaded	`/libs:static`
	`/threads`
	`/dbglibs`
		`/MTd`

Multithreaded debug DLLs	`/libs:dll`
	`/threads`
	`/dbglibs`
		`/MDd`

Debug Fortran QuickWin multi-thread applications	`/libs:qwin`	None

Type of Library	Options Required	Alternate Option
	/dbglibs	
Debug Fortran standard graphics (QuickWin single-thread) applications	/libs:qwins /dbglibs	None

IDE Equivalent

None

Alternate Options

None

dll

Specifies that a program should be linked as a dynamic-link (DLL) library.

Syntax

Linux OS and macOS:

None

Windows OS:

/dll

Arguments

None

Default

OFF The program is not linked as a dynamic-link (DLL) library.

Description

This option specifies that a program should be linked as a dynamic-link (DLL) library instead of an executable (.exe) file. It overrides any previous specification of run-time routines to be used and enables the /libs:dll option.

If you use this option with the /libs:qwin or /libs:qwins option, the compiler issues a warning.

IDE Equivalent

None

Alternate Options

Linux and macOS*: None

Windows: /LD

dynamic-linker

Specifies a dynamic linker other than the default.

Syntax

Linux OS:

`-dynamic-linker file`

macOS:

`None`

Windows OS:

`None`

Arguments

file	Is the name of the dynamic linker to be used.

Default

OFF	The default dynamic linker is used.

Description

This option lets you specify a dynamic linker other than the default.

IDE Equivalent

None

Alternate Options

None

dynamiclib

Invokes the libtool command to generate dynamic libraries.

Syntax

Linux OS:

`None`

macOS:

`-dynamiclib`

Windows OS:

`None`

Arguments

None

Default

OFF	The compiler produces an executable.

Description

This option invokes the `libtool` command to generate dynamic libraries.

When passed this option, the compiler uses the `libtool` command to produce a dynamic library instead of an executable when linking.

To build static libraries, you should specify option `-staticlib` or `libtool -static <objects>`.

IDE Equivalent

None

Alternate Options

None

See Also

staticlib
compiler option

extlnk

Specifies file extensions to be passed directly to the linker.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/extlnk:`*`ext`*

Arguments

`ext`	Are the file extensions to be passed directly to the linker.

Default

OFF	Only the file extensions recognized by the compiler are passed to the linker.

Description

This option specifies file extensions (*ext*) to be passed directly to the linker. It is useful if your source file has a nonstandard extension.

You can specify one or more file extensions. A leading period before each extension is optional; for example, `/extlnk:myobj` and `/extlnk:.myobj` are equivalent.

IDE Equivalent

None

Alternate Options

None

F (Windows*)

Specifies the stack reserve amount for the program.

Syntax

Linux OS:

None

macOS:

None

Windows OS:

/Fn

Arguments

n	Is the stack reserve amount. It can be specified as a decimal integer or as a hexadecimal constant by using a C-style convention (for example, /F0x1000).

Default

OFF	The stack size default is chosen by the operating system.

Description

This option specifies the stack reserve amount for the program. The amount (*n*) is passed to the linker.

Note that the linker property pages have their own option to do this.

IDE Equivalent

None

Alternate Options

None

F (macOS*)

Adds a framework directory to the head of an include file search path.

Syntax

Linux OS:

None

macOS:

-Fdir

Windows OS:

None

Arguments

dir	Is the name for the framework directory.

Default

OFF	The compiler does not add a framework directory to the head of an include file search path.

Description

This option adds a framework directory to the head of an include file search path.

IDE Equivalent

None

Alternate Options

None

fuse-ld

Tells the compiler to use a different linker instead of the default linker (ld).

Syntax

Linux OS:

`-fuse-ld=`*`keyword`*

macOS:

`-fuse-ld=`*`keyword`*

Windows OS:

`None`

Arguments

`keyword`	Possible values are:	
	`bfd`	Tells the compiler to use the bfd linker.
	`gold`	Tells the compiler to use the gold linker.

Default

ld	The compiler uses the ld linker by default.

Description

This option tells the compiler to use a different linker instead of default linker (ld).

This option is provided for compatibility with gcc.

IDE Equivalent

None

Alternate Options

None

l

Tells the linker to search for a specified library when linking.

Syntax

Linux OS:

`-l`*string*

macOS:

`-l`*string*

Windows OS:

None

Arguments

string	Specifies the library (lib*string*) that the linker should search.

Default

OFF	The linker searches for standard libraries in standard directories.

Description

This option tells the linker to search for a specified library when linking.

When resolving references, the linker normally searches for libraries in several standard directories, in directories specified by the `L` option, then in the library specified by the `l` option.

The linker searches and processes libraries and object files in the order they are specified. So, you should specify this option following the last object file it applies to.

IDE Equivalent

None

Alternate Options

None

See Also

`L` compiler option

L

Tells the linker to search for libraries in a specified directory before searching the standard directories.

Syntax

Linux OS:

`-L`*dir*

macOS:

`-L`*dir*

Windows OS:

None

Arguments

dir Is the name of the directory to search for libraries.

Default

OFF The linker searches the standard directories for libraries.

Description

This option tells the linker to search for libraries in a specified directory before searching for them in the standard directories.

IDE Equivalent

None

Alternate Options

None

See Also

`l` compiler option

libs

Tells the compiler which type of run-time library to link to.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/libs[:keyword]`

Arguments

keyword Specifies the type of run-time library to link to. Possible values are:

`dll`	Specifies a multithreaded, dynamic-link (DLL) library.
`qwin`	Specifies the Fortran QuickWin library.
`qwins`	Specifies the Fortran Standard Graphics library.
`static`	Specifies a multi-threaded, static run-time library. This is the same as specifying `/libs` with no *keyword*. Note that some libraries do not have a static version, such as the OpenMP run-time libraries or the coarray run-time libraries.

Default

`/libs` The compiler links to a multi-threaded, static run-time library.

Description

This option tells the compiler which type of run-time library to link to.

This option is processed by the compiler, which adds directives to the compiled object file that are processed by the linker.

There are several types of libraries you can link to, depending on which compiler options you specify, as shown in the table below.

If you use the `/libs:dll` option and an unresolved reference is found in the DLL, it gets resolved when the program is executed, during program loading, reducing executable program size.

If you use the `/libs:qwin` or `/libs:qwins` option with the `/dll` option, the compiler issues a warning.

You cannot use the `/libs:qwin` option and options `/libs:dll /threads`.

The following table shows which options to specify for different run-time libraries:

Type of Library	Options Required	Alternate Option
Multithreaded static	`/libs` (or `/threads`)	`/MT`
Debug multithreaded static	`/libs` (or `/threads`) and `/dbglibs`	`/MTd`
Multithreaded DLLs	`/libs:dll`	`/MD`
Multithreaded debug DLLs	`/libs:dll` and `/dbglibs`	`/MDd`
Fortran QuickWin multi-doc applications	`/libs:qwin`	`/MW`
Fortran standard graphics (QuickWin single-doc) applications	`/libs:qwins`	`/MWs`
Debug Fortran QuickWin multi-doc applications	`/libs:qwin` `/dbglibs`	None
Debug Fortran standard graphics (QuickWin single-doc) applications	`/libs:qwins` `/dbglibs`	None

NOTE
This option adds directives to the compiled code, which the linker then reads without further input from the driver.

NOTE
Starting with the 13.0 release of the Intel compilers, the Intel® OpenMP* library is provided in DLL form only.

IDE Equivalent

Visual Studio: **Libraries > Runtime Library** (`/libs:{dll|qwin|qwins}`, `/threads`, `/dbglibs`)

Eclipse: None

Xcode: None

Alternate Options

`/libs`	Linux and macOS*: `-threads` Windows: `/threads`
`/libs:dll`	Linux and macOS*: None Windows: `/MD`
`/libs:qwin`	Linux and macOS*: None Windows: `/MW`
`/libs:qwins`	Linux and macOS*: None Windows: `/MWs`

`dbglibs` compiler option

link

Passes user-specified options directly to the linker at compile time.

Syntax

Linux OS:

`None`

macOS:

`None`

Windows OS:

`/link`

Arguments

None

Default

OFF No user-specified options are passed directly to the linker.

Description

This option passes user-specified options directly to the linker at compile time.

All options that appear following `/link` are passed directly to the linker.

IDE Equivalent

None

Alternate Options

None

See Also

`Xlinker` compiler option

map

Tells the linker to generate a link map file.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/map[:filename]`

`/nomap`

Arguments

`filename` Is the name for the link map file. It can be a file name or a directory name.

Default

`/nomap` No link map is generated.

Description

This option tells the linker to generate a link map file.

IDE Equivalent

Visual Studio: **Linker > Debugging > Generate Map File** (/MAP)

Eclipse: None

Xcode: None

Alternate Options

None

MD

Tells the linker to search for unresolved references in a multithreaded, dynamic-link run-time library.

Syntax

Linux OS:

`None`

macOS:

`None`

Windows OS:

`/MD`

`/MDd`

Arguments

None

Default

OFF The linker searches for unresolved references in a multi-threaded, static run-time library.

Description

This option tells the linker to search for unresolved references in a multithreaded, dynamic-link (DLL) run-time library. This is the same as specifying options `/libs:dll /threads /dbglibs`. You can also specify `/MDd`, where `d` indicates a debug version.

This option is processed by the compiler, which adds directives to the compiled object file that are processed by the linker.

IDE Equivalent

Visual Studio: **Libraries > Runtime Library**

Eclipse: None

Xcode: None

Alternate Options

None

See Also

`libs` compiler option

`threads` compiler option

MDs

Tells the linker to search for unresolved references in a single-threaded, dynamic-link run-time library. This is a deprecated option. There is no replacement option.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/MDs`

`/MDsd`

Arguments

None

Default

OFF The linker searches for unresolved references in a single-threaded, static run-time library.

Description

This option tells the linker to search for unresolved references in a single-threaded, dynamic-link (DLL) run-time library.

You can also specify `/MDsd`, where *d* indicates a debug version.

IDE Equivalent

None

Alternate Options

`/MDs`	Linux and macOS*: None Windows: `/libs:dll`

See Also

`libs` compiler option

MT

Tells the linker to search for unresolved references in a multithreaded, static run-time library.

Syntax

Linux OS:

`None`

macOS:

`None`

Windows OS:

`/MT`

`/MTd`

Arguments

None

Default

`/MT /noreentrancy:threaded`	The linker searches for unresolved references in a multithreaded, static run-time library.

Description

This option tells the linker to search for unresolved references in a multithreaded, static run-time library. This is the same as specifying options `/libs:static /threads /noreentrancy`. You can also specify `/MTd`, where `d` indicates a debug version.

This option is processed by the compiler, which adds directives to the compiled object file that are processed by the linker.

IDE Equivalent

Visual Studio: **Libraries > Runtime Library**

Eclipse: None

Xcode: None

Alternate Options

None

See Also

Qvc compiler option

nodefaultlibs

Prevents the compiler from using standard libraries when linking.

Syntax

Linux OS:

```
-nodefaultlibs
```

macOS:

```
-nodefaultlibs
```

Windows OS:

```
None
```

Arguments

None

Default

OFF	The standard libraries are linked.

Description

This option prevents the compiler from using standard libraries when linking.

IDE Equivalent

None

Alternate Options

None

See Also

nostdlib compiler option

nofor-main

Specifies that the main program is not written in Fortran.

Syntax

Linux OS and macOS:

```
-nofor-main
```

Windows OS:

```
None
```

Arguments

None

Default

OFF The compiler assumes the main program is written in Fortran.

Description

This option specifies that the main program is not written in Fortran. It is a link-time option that prevents the compiler from linking `for_main.o` into applications.

For example, if the main program is written in C and calls a Fortran subprogram, specify `-nofor-main` when compiling the program with the `ifort` command.

If you omit this option, the main program must be a Fortran program.

IDE Equivalent

None

Alternate Options

None

nostartfiles

Prevents the compiler from using standard startup files when linking.

Syntax

Linux OS:

`-nostartfiles`

macOS:

`-nostartfiles`

Windows OS:

`None`

Arguments

None

Default

OFF The compiler uses standard startup files when linking.

Description

This option prevents the compiler from using standard startup files when linking.

IDE Equivalent

None

Alternate Options

None

See Also

`nostdlib` compiler option

nostdlib

Prevents the compiler from using standard libraries and startup files when linking.

Syntax

Linux OS:

```
-nostdlib
```

macOS:

```
-nostdlib
```

Windows OS:

```
None
```

Arguments

None

Default

OFF The compiler uses standard startup files and standard libraries when linking.

Description

This option prevents the compiler from using standard libraries and startup files when linking.

IDE Equivalent

None

Alternate Options

None

See Also

`nodefaultlibs` compiler option

`nostartfiles` compiler option

pie

Determines whether the compiler generates position-independent code that will be linked into an executable.

Syntax

Linux OS:

```
-pie
```

```
-no-pie
```

macOS:

```
-pie
```

```
-no-pie
```

Windows OS:

None

Arguments

None

Default

varies On Linux* and on macOS* versions less than 10.7, the default is -no-pie. On macOS* 10.7 or greater, the default is -pie.

Description

This option determines whether the compiler generates position-independent code that will be linked into an executable. To enable generation of position-independent code that will be linked into an executable, specify `-pie`.

To disable generation of position-independent code that will be linked into an executable, specify `-no-pie`.

IDE Equivalent

None

Alternate Options

None

See Also

`fpic`
compiler option

pthread

Tells the compiler to use pthreads library for multithreading support.

Syntax

Linux OS:

`-pthread`

macOS:

`-pthread`

Windows OS:

None

Arguments

None

Default

OFF The compiler does not use pthreads library for multithreading support.

Description

Tells the compiler to use pthreads library for multithreading support.

IDE Equivalent

None

Alternate Options

Linux and macOS*: `-reentrancy threaded`

Windows: `/reentrancy:threaded`

shared

Tells the compiler to produce a dynamic shared object instead of an executable.

Syntax

Linux OS:

`-shared`

macOS:

`None`

Windows OS:

`None`

Arguments

None

Default

OFF	The compiler produces an executable.

Description

This option tells the compiler to produce a dynamic shared object (DSO) instead of an executable. This includes linking in all libraries dynamically and passing `-shared` to the linker.

You must specify option `fpic` for the compilation of each object file you want to include in the shared library.

IDE Equivalent

None

Alternate Options

None

See Also

`dynamiclib` compiler option

`fpic` compiler option

`Xlinker` compiler option

shared-intel

Causes Intel-provided libraries to be linked in dynamically.

Syntax

Linux OS:

`-shared-intel`

macOS:

`-shared-intel`

Windows OS:

`None`

Arguments

None

Default

OFF Intel® libraries are linked in statically, with the exception of Intel's coarray runtime support library and Intel's OpenMP* runtime support library, which are linked in dynamically. To link the OpenMP* runtime support library statically, specify option `-qopenmp-link=static`.

Description

This option causes Intel-provided libraries to be linked in dynamically. It is the opposite of `-static-intel`.

This option is processed by the ifort (icc/icpc) command that initiates linking, adding library names explicitly to the link command.

If you specify option `-mcmodel=medium` or `-mcmodel=large`, it sets option `-shared-intel`.

NOTE
On macOS* systems, when you set "Intel Runtime Libraries" to "Dynamic", you must also set the DYLD_LIBRARY_PATH environment variable within Xcode* or an error will be displayed.

IDE Equivalent

Visual Studio: None

Eclipse: None

Xcode: **Runtime > Intel Runtime Libraries**

Alternate Options

None

See Also

`static-intel` compiler option
`qopenmp-link` compiler option

shared-libgcc

Links the GNU libgcc library dynamically.

Syntax

Linux OS:

`-shared-libgcc`

macOS:

`None`

Windows OS:

`None`

Arguments

None

Default

`-shared-libgcc`	The compiler links the `libgcc` library dynamically.

Description

This option links the GNU `libgcc` library dynamically. It is the opposite of option `static-libgcc`.

This option is processed by the ifort (icc/icpc) command that initiates linking, adding library names explicitly to the link command.

This option is useful when you want to override the default behavior of the `static` option, which causes all libraries to be linked statically.

IDE Equivalent

None

Alternate Options

None

See Also

static-libgcc compiler option

static

Prevents linking with shared libraries.

Syntax

Linux OS:

`-static`

macOS:

`None`

Windows OS:

`/static`

Arguments

None

Default

varies The compiler links with shared GNU libraries (Linux* systems) or shared Microsoft* libraries (Windows* systems) and it links with static Intel libraries, with the exception of the OpenMP* libraries and coarray library libicaf, which are linked in dynamically.

On Windows* systems, option /static is equivalent to option /MT.

Description

This option prevents linking with shared libraries. It causes the executable to link all libraries statically.

NOTE
This option does not cause static linking of libraries for which no static version is available, such as the OpenMP run-time libraries on Windows* or the coarray run-time libraries. These libraries can only be linked dynamically.

IDE Equivalent

None

Alternate Options

None

See Also

`MT` compiler option

`Qvc` compiler option

`static-intel` compiler option

static-intel

Causes Intel-provided libraries to be linked in statically.

Syntax

Linux OS:

`-static-intel`

macOS:

`-static-intel`

Windows OS:

`None`

Arguments

None

Default

ON Intel® libraries are linked in statically, with the exception of Intel's coarray runtime support library and Intel's OpenMP* runtime support library, which are linked in dynamically. To link the OpenMP* runtime support library statically, specify option `-qopenmp-link=static`.

Description

This option causes Intel-provided libraries to be linked in statically with certain exceptions (see the Default above). It is the opposite of `-shared-intel`.

This option is processed by the ifort command that initiates linking, adding library names explicitly to the link command.

If you specify option `-static-intel` while option `-mcmodel=medium` or `-mcmodel=large` is set, an error will be displayed.

If you specify option `-static-intel` and any of the Intel-provided libraries have no static version, a diagnostic will be displayed.

IDE Equivalent

Visual Studio: None

Eclipse: None

Xcode: **Runtime > Intel Runtime Libraries**

Alternate Options

None

See Also

`shared-intel` compiler option
`qopenmp-link` compiler option

static-libgcc

Links the GNU libgcc library statically.

Syntax

Linux OS:

`-static-libgcc`

macOS:

`None`

Windows OS:

`None`

Arguments

None

Default

OFF The compiler links the GNU `libgcc` library dynamically.

Description

This option links the GNU `libgcc` library statically. It is the opposite of option `-shared-libgcc`.

This option is processed by the ifort command that initiates linking, adding library names explicitly to the link command.

This option is useful when you want to override the default behavior, which causes the library to be linked dynamically.

NOTE
If you want to use traceback, you must also link to the static version of the `libgcc` library. This library enables printing of backtrace information.

IDE Equivalent

None

Alternate Options

None

See Also

`shared-libgcc` compiler option
`static-libstdc++` compiler option

static-libstdc++

Links the GNU libstdc++ library statically.

Syntax

Linux OS:

`-static-libstdc++`

macOS:

`None`

Windows OS:

`None`

Arguments

None

Default

OFF The compiler links the GNU `libstdc++` library dynamically.

Description

This option links the GNU `libstdc++` library statically. This option is processed by the ifort (icc/icpc) command that initiates linking, adding library names explicitly to the link command.

This option is useful when you want to override the default behavior, which causes the library to be linked dynamically.

IDE Equivalent

None

Alternate Options

None

See Also

`static-libgcc` compiler option

staticlib

Invokes the libtool command to generate static libraries.

Syntax

Linux OS:

`None`

macOS:

`-staticlib`

Windows OS:

`None`

Arguments

None

Default

OFF The compiler produces an executable.

Description

This option invokes the `libtool` command to generate static libraries. This option is processed by the command that initiates linking, adding library names explicitly to the link command.

When passed this option, the compiler uses the `libtool` command to produce a static library instead of an executable when linking.

To build dynamic libraries, you should specify option `-dynamiclib` or `libtool -dynamic <objects>`.

IDE Equivalent

None

Alternate Options

None

See Also

dynamiclib
compiler option

T

Tells the linker to read link commands from a file.

Syntax

Linux OS:

`-T`*`filename`*

macOS:

`None`

Windows OS:

`None`

Arguments

filename Is the name of the file.

Default

OFF The linker does not read link commands from a file.

Description

This option tells the linker to read link commands from a file.

IDE Equivalent

None

Alternate Options

None

threads

Tells the linker to search for unresolved references in a multithreaded run-time library.

Syntax

Linux OS and macOS:

`-threads`

`-nothreads`

Windows OS:

`/threads`

`/nothreads`

Arguments

None

Default

`threads` The linker searches for unresolved references in a library that supports enabling thread-safe operation.

Description

This option tells the linker to search for unresolved references in a multithreaded run-time library.

This option sets option `reentrancy threaded`.

Windows systems: The following table shows which options to specify for a multithreaded run-time library.

Type of Library	Options Required	Alternate Option
Multithreaded	`/libs:static` `/threads`	`/MT`
Debug multithreaded	`/libs:static`	`/MTd`

Type of Library	Options Required	Alternate Option
	/threads	
	/dbglibs	
Multithreaded DLLs	/libs:dll	/MD
	/threads	
Multithreaded debug DLLs	/libs:dll	/MDd
	/threads	
	/dbglibs	

To ensure that a threadsafe and/or reentrant run-time library is linked and correctly initialized, option `threads` should also be used for the link step and for the compilation of the main routine.

NOTE
On Windows* systems, this option is processed by the compiler, which adds directives to the compiled object file that are processed by the linker. On Linux* and macOS* systems, this option is processed by the `ifort` command that initiates linking, adding library names explicitly to the link command.

IDE Equivalent

None

Alternate Options

None

See Also

`reentrancy` compiler option

v

Specifies that driver tool commands should be displayed and executed.

Syntax

Linux OS:

`-v [filename]`

macOS:

`-v [filename]`

Windows OS:

`None`

Arguments

filename	Is the name of a source file to be compiled. A space must appear before the file name.

Default

OFF No tool commands are shown.

Description

This option specifies that driver tool commands should be displayed and executed.

If you use this option without specifying a source file name, the compiler displays only the version of the compiler.

If you want to display processing information (pass information and source file names), specify keyword `all` for the `watch` option.

IDE Equivalent

None

Alternate Options

Linux and macOS*: `-watch cmd`

Windows: `/watch:cmd`

See Also

`dryrun` compiler option
`watch` compiler option

Wa

Passes options to the assembler for processing.

Syntax

Linux OS:

`-Wa,option1[,option2,...]`

macOS:

`-Wa,option1[,option2,...]`

Windows OS:

`None`

Arguments

option	Is an assembler option. This option is not processed by the driver and is directly passed to the assembler.

Default

OFF No options are passed to the assembler.

Description

This option passes one or more options to the assembler for processing. If the assembler is not invoked, these options are ignored.

IDE Equivalent

None

Alternate Options

None

winapp

Tells the compiler to create a graphics or Fortran Windows application and link against the most commonly used libraries.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/winapp`

Arguments

None

Default

OFF	No graphics or Fortran Windows application is created.

Description

This option tells the compiler to create a graphics or Fortran Windows application and link against the most commonly used libraries.

This option is processed by the compiler, which adds directives to the compiled object file that are processed by the linker.

IDE Equivalent

Visual Studio: **Libraries > Use Common Windows Libraries**

Eclipse: None

Xcode: None

Alternate Options

Linux and macOS*: None

Windows: `/MG`

Wl

Passes options to the linker for processing.

Syntax

Linux OS:

`-Wl,`*`option1`*`[,`*`option2`*`,...]`

macOS:

`-Wl,`*`option1`*`[,`*`option2`*`,...]`

Windows OS:

`None`

Arguments

option	Is a linker option. This option is not processed by the driver and is directly passed to the linker.

Default

OFF	No options are passed to the linker.

Description

This option passes one or more options to the linker for processing. If the linker is not invoked, these options are ignored.

This option is equivalent to specifying option `-Qoption,link,`*options*.

IDE Equivalent

None

Alternate Options

None

See Also

`Qoption` compiler option

Wp

Passes options to the preprocessor.

Syntax

Linux OS:

`-Wp,`*option1*`[,`*option2*`,...]`

macOS:

`-Wp,`*option1*`[,`*option2*`,...]`

Windows OS:

`None`

Arguments

option	Is a preprocessor option. This option is not processed by the driver and is directly passed to the preprocessor.

Default

OFF	No options are passed to the preprocessor.

Description

This option passes one or more options to the preprocessor. If the preprocessor is not invoked, these options are ignored.

This option is equivalent to specifying option `-Qoption,`*fpp, options*.

IDE Equivalent

None

Alternate Options

None

See Also

`Qoption` compiler option

Xlinker

Passes a linker option directly to the linker.

Syntax

Linux OS:

`-Xlinker` *option*

macOS:

`-Xlinker` *option*

Windows OS:

`None`

Arguments

option	Is a linker option.

Default

OFF	No options are passed directly to the linker.

Description

This option passes a linker option directly to the linker. If `-Xlinker -shared` is specified, only `-shared` is passed to the linker and no special work is done to ensure proper linkage for generating a shared object. `-Xlinker` just takes whatever arguments are supplied and passes them directly to the linker.

If you want to pass compound options to the linker, for example "`-L $HOME/lib`", you must use the following method:

```
-Xlinker -L -Xlinker $HOME/lib
```

IDE Equivalent

None

Alternate Options

None

`shared` compiler option
`link` compiler option

Miscellaneous Options

bigobj

Increases the number of sections that an object file can contain.

Syntax

Linux OS:

`None`

macOS:

`None`

Windows OS:

`/bigobj`

Arguments

None

Default

OFF	An object file can hold up to 65,536 (2**16) addressable sections.

Description

This option increases the number of sections that an object file can contain. It increases the address capacity to 4,294,967,296(2**32).

This option may be helpful for .obj files that can hold more sections, such as machine generated code.

IDE Equivalent

None

Alternate Options

None

dryrun

Specifies that driver tool commands should be shown but not executed.

Syntax

Linux OS:

`-dryrun`

macOS:

`-dryrun`

Windows OS:

`None`

Arguments

None

Default

OFF No tool commands are shown, but they are executed.

Description

This option specifies that driver tool commands should be shown but not executed.

IDE Equivalent

None

None

Alternate Options

None

See Also

- v compiler option

dumpmachine

Displays the target machine and operating system configuration.

Syntax

Linux OS:

```
-dumpmachine
```

macOS:

```
-dumpmachine
```

Windows OS:

```
None
```

Arguments

None

Default

OFF The compiler does not display target machine or operating system information.

Description

This option displays the target machine and operating system configuration. No compilation is performed.

IDE Equivalent

None

Alternate Options

None

extfor

Specifies file extensions to be processed by the compiler as Fortran files.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/extfor:`*`ext`*

Arguments

ext	Are the file extensions to be processed as a Fortran file.

Default

OFF	Only the file extensions recognized by the compiler are processed as Fortran files.

Description

This option specifies file extensions (*ext*) to be processed by the compiler as Fortran files. It is useful if your source file has a nonstandard extension.

You can specify one or more file extensions. A leading period before each extension is optional; for example, `/extfor:myf95` and `/extfor:.myf95` are equivalent.

IDE Equivalent

None

Alternate Options

None

See Also

Tf compiler option

extfpp

Specifies file extensions to be recognized as a file to be preprocessed by the Fortran preprocessor.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/extfpp:`*`ext`*

Arguments

ext	Are the file extensions to be preprocessed by the Fortran preprocessor.

Default

OFF Only the file extensions recognized by the compiler are preprocessed by `fpp`.

Description

This option specifies file extensions (*ext*) to be recognized as a file to be preprocessed by the Fortran preprocessor (`fpp`). It is useful if your source file has a nonstandard extension.

You can specify one or more file extensions. A leading period before each extension is optional; for example, `/extfpp:myfpp` and `/extfpp:.myfpp` are equivalent.

IDE Equivalent

None

Alternate Options

None

global-hoist, Qglobal-hoist

Enables certain optimizations that can move memory loads to a point earlier in the program execution than where they appear in the source.

Syntax

Linux OS:

`-global-hoist`

`-no-global-hoist`

macOS:

`-global-hoist`

`-no-global-hoist`

Windows OS:

`/Qglobal-hoist`

`/Qglobal-hoist-`

Arguments

None

Default

`-global-hoist` or `/Qglobal-hoist` Certain optimizations are enabled that can move memory loads.

Description

This option enables certain optimizations that can move memory loads to a point earlier in the program execution than where they appear in the source. In most cases, these optimizations are safe and can improve performance.

The negative form of the option is useful for some applications, such as those that use shared or dynamically mapped memory, which can fail if a load is moved too early in the execution stream (for example, before the memory is mapped).

IDE Equivalent

None

Alternate Options

None

help

Displays all available compiler options or a category of compiler options.

Syntax

Linux OS:

`-help[category]`

macOS:

`-help[category]`

Windows OS:

`/help[category]`

Arguments

category Is a category or class of options to display. Possible values are:

`advanced`	Displays advanced optimization options that allow fine tuning of compilation or allow control over advanced features of the compiler.
`codegen`	Displays Code Generation options.
`compatibility`	Displays options affecting language compatibility.
`component`	Displays options for component control.
`data`	Displays options related to interpretation of data in programs or the storage of data.
`deprecated`	Displays options that have been deprecated.
`diagnostics`	Displays options that affect diagnostic messages displayed by the compiler.
`float`	Displays options that affect floating-point operations.
`help`	Displays all the available help categories.
`inline`	Displays options that affect inlining.
`ipo`	Displays Interprocedural Optimization (IPO) options
`language`	Displays options affecting the behavior of the compiler language features.

`link`	Displays linking or linker options.
`misc`	Displays miscellaneous options that do not fit within other categories.
`openmp`	Displays OpenMP and parallel processing options.
`opt`	Displays options that help you optimize code.
`output`	Displays options that provide control over compiler output.
`pgo`	Displays Profile Guided Optimization (PGO) options.
`preproc`	Displays options that affect preprocessing operations.
`reports`	Displays options for optimization reports.

Default

OFF No list is displayed unless this compiler option is specified.

Description

This option displays all available compiler options or a category of compiler options. If category is not specified, all available compiler options are displayed.

IDE Equivalent

None

Alternate Options

Linux and macOS*: None

Windows: `/?`

intel-freestanding

Lets you compile in the absence of a gcc environment.

Syntax

Linux OS:

`-intel-freestanding[=ver]`

macOS:

`None`

Windows OS:

`None`

Arguments

ver	Is a three-digit number that is used to determine the gcc version that the compiler should be compatible with for compilation. It also sets the corresponding GNUC macros.

The number will be normalized to reflect the gcc compiler version numbering scheme. For example, if you specify 493, it indicates the compiler should be compatible with gcc version 4.9.3.

Default

OFF The compiler uses default heuristics when choosing the gcc environment.

Description

This option lets you compile in the absence of a gcc environment. It disables any external compiler calls (such as calls to gcc) that the compiler driver normally performs by default.

This option also removes any default search locations for header and library files. So, for successful compilation and linking, you must provide these search locations.

This option does not affect ld, as, or fpp. They will be used for compilation as needed.

NOTE
This option does not imply option `-nostdinc -nostdlib`. If you want to assure a clean environment for compilation (including removal of Intel-specific header locations and libs), you should specify `-nostdinc` and/or `-nostdlib`.

NOTE
This option is supported for any Linux-target compiler, including a Windows-host to Linux-target compiler.

IDE Equivalent

None

Alternate Options

None

See Also

intel-freestanding-target-os compiler option
nostdlib compiler option
nostdinc compiler option, which is an alternate option for option X

intel-freestanding-target-os

Lets you specify the target operating system for compilation.

Syntax

Linux OS:

`-intel-freestanding-target-os=`*os*

macOS:

`None`

Windows OS:

`None`

Arguments

os	Is the target operating system for the Linux compiler. Currently, the only possible value is `linux`.

Default

OFF	The installed gcc determines the target operating system.

Description

This option lets you specify the target operating system for compilation. It sets option `-intel-freestanding`.

> **NOTE**
> This option is supported for any Linux-target compiler, including a Windows-host to Linux-target compiler.

IDE Equivalent

None

Alternate Options

None

See Also

intel-freestanding compiler option

libdir

Controls whether linker options for search libraries are included in object files generated by the compiler.

Syntax

Linux OS and macOS:

`None`

Windows OS:

`/libdir[:`*`keyword`*` ]`

`/nolibdir`

Arguments

keyword	Specifies the linker search options. Possible values are:
`none`	Prevents any linker search options from being included into the object file. This is the same as specifying `/nolibdir`.
`[no]automatic`	Determines whether linker search options for libraries automatically determined by the `ifort` command driver (default libraries) are included in the object file.
`[no]user`	Determines whether linker search options for libraries specified by the OBJCOMMENT source directives are included in the object file.

`all` Causes linker search options for the following libraries:

- Libraries automatically determined by the `ifort` command driver (default libraries)
- Libraries specified by the OBJCOMMENT directive to be included in the object file

This is the same as specifying `/libdir`.

Default

`/libdir:all` Linker search options for libraries automatically determined by the `ifort` command driver (default libraries) and libraries specified by the OBJCOMMENT directive are included in the object file.

Description

This option controls whether linker options for search libraries (`/DEFAULTLIB:library`) are included in object files generated by the compiler.

The linker option `/DEFAULTLIB:library` adds one library to the list of libraries that the linker searches when resolving references. A library specified with `/DEFAULTLIB:library` is searched after libraries specified on the command line and before default libraries named in .obj files.

IDE Equivalent

Visual Studio: **Libraries > Disable Default Library Search Rules** (`/libdir:[no]automatic`)

Libraries > Disable OBJCOMMENT Library Name in Object (`/libdir:[no]user`)

Eclipse: None

Xcode: None

Alternate Options

`/libdir:none` Linux and macOS*: None

Windows: `/Zl`

logo

Displays the compiler version information.

Syntax

Linux OS and macOS:

`-logo`

`-nologo`

Windows OS:

`/logo`

`/nologo`

Arguments

None

Default

Linux* and macOS*: `nologo`	The compiler version information is not displayed.
Windows* : `logo`	The compiler version information is displayed.

Description

This option displays the startup banner, which contains the following compiler information:

- The name of the compiler and its applicable architecture
- The major and minor version of the compiler, the update number, and the package number(for example, Version 11.1.0.047)
- The specific build and build date (for example, Build <builddate>)
- The copyright date of the software

This option can be placed anywhere on the command line.

IDE Equivalent

Visual Studio: **General > Suppress Startup Banner** (`/nologo`)

Eclipse: None

Xcode: **General > Show Startup Banner** (`-V`)

Alternate Options

Linux and macOS*: `-V`

Windows: None

multiple-processes, MP

Creates multiple processes that can be used to compile large numbers of source files at the same time.

Syntax

Linux OS:

`-multiple-processes[=n]`

macOS:

`-multiple-processes[=n]`

Windows OS:

`/MP[:n]`

Arguments

n	Is the maximum number of processes that the compiler should create.

Default

OFF	A single process is used to compile source files.

Description

This option creates multiple processes that can be used to compile large numbers of source files at the same time. It can improve performance by reducing the time it takes to compile source files on the command line.

This option causes the compiler to create one or more copies of itself, each in a separate process. These copies simultaneously compile the source files.

If *n* is not specified for this option, the default value is as follows:

- On Windows* systems, the value is based on the setting of the NUMBER_OF_PROCESSORS environment variable.
- On Linux* and macOS* systems, the value is 2.

This option applies to compilations, but not to linking or link-time code generation.

IDE Equivalent

Visual Studio: **General > Multi-processor Compilation**

Eclipse: None

Xcode: None

Alternate Options

None

print-sysroot

Prints the target sysroot directory that is used during compilation.

Syntax

Linux OS:

`-print-sysroot`

macOS:

`None`

Windows OS:

`None`

Arguments

None

Default

OFF	Nothing is printed.

Description

This option prints the target sysroot directory that is used during compilation.

This is the target sysroot directory that is specified in an environment file or in option `--sysroot`. This option is only effective if a target sysroot has been specified.

IDE Equivalent

None

Alternate Options

None

See Also

`sysroot` compiler option

save-temps, Qsave-temps

Tells the compiler to save intermediate files created during compilation.

Syntax

Linux OS:

`-save-temps`

`-no-save-temps`

macOS:

`-save-temps`

`-no-save-temps`

Windows OS:

`/Qsave-temps`

`/Qsave-temps-`

Arguments

None

Default

Linux* and macOS* systems: `-no-save-temps` Windows* systems: .obj files are saved	On Linux and macOS* systems, the compiler deletes intermediate files after compilation is completed. On Windows systems, the compiler saves only intermediate object files after compilation is completed.

Description

This option tells the compiler to save intermediate files created during compilation. The names of the files saved are based on the name of the source file; the files are saved in the current working directory.

If option `[Q]save-temps` is specified, the following occurs:

- The object .o file (Linux and macOS*) or .obj file (Windows) is saved.
- The assembler .s file (Linux and macOS*) or .asm file (Windows) is saved if you specified the `[Q]use-asm` option.
- The .i or .i90 file is saved if the fpp preprocessor is invoked.

If `-no-save-temps` is specified on Linux or macOS* systems, the following occurs:

- The .o file is put into `/tmp` and deleted after calling `ld`.
- The preprocessed file is not saved after it has been used by the compiler.

If `/Qsave-temps-` is specified on Windows systems, the following occurs:

- The .obj file is not saved after the linker step.

- The preprocessed file is not saved after it has been used by the compiler.

NOTE
This option only saves intermediate files that are normally created during compilation.

IDE Equivalent

None

Alternate Options

None

Example

If you compile program `my_foo.F` on a Linux or macOS* system and you specify option `-save-temps` and option `-use-asm`, the compilation will produce `files my_foo.o`, `my_foo.s`, and `my_foo.i`.

If you compile program `my_foo.fpp` on a Windows system and you specify option `/Qsave-temps` and option `/Quse-asm`, the compilation will produce `files my_foo.obj`, `my_foo.asm`, and `my_foo.i`.

sox

Tells the compiler to save the compilation options and version number in the executable file. It also lets you choose whether to include lists of certain routines.

Syntax

Linux OS:

`-sox[=keyword[,keyword]]`

`-no-sox`

macOS:

`None`

Windows OS:

`None`

Arguments

keyword Is the routine information to include. Possible values are:

`inline`	Includes a list of the routines that were inlined in each object.
`profile`	Includes a list of the routines that were compiled with the `-prof-use` option and for which the .dpi file had profile information, and an indication for each as to whether the profile information was USED (matched) or IGNORED (mismatched).

Default

`-no-sox` The compiler does not save these informational strings in the object file.

Description

This option tells the compiler to save the compilation options and version number in the executable file. It also lets you choose whether to include lists of certain routines. The information is embedded as a string in each object file or assembly output.

If you specify option `sox` with no *keyword*, the compiler saves the compiler options and version number used in the compilation of the objects that make up the executable.

When you specify this option, the size of the executable on disk is increased slightly. Each *keyword* you specify increases the size of the executable. When you link the object files into an executable file, the linker places each of the information strings into the header of the executable. It is then possible to use a tool, such as a strings utility, to determine what options were used to build the executable file.

IDE Equivalent

None

Alternate Options

None

Example

The following commands are equivalent:

```
-sox=profile -sox=inline
-sox=profile,inline
```

You can use the negative form of the option to disable and reset the option. For example:

```
-sox=profile -no-sox -sox=inline      ! This means -sox=inline
```

See Also

`prof-use, Qprof-use` compiler option

sysroot

Specifies the root directory where headers and libraries are located.

Syntax

Linux OS:

`--sysroot=`*`dir`*

macOS:

`None`

Windows OS:

`None`

Arguments

dir	Specifies the local directory that contains copies of target libraries in the corresponding subdirectories.

Default

Off	The compiler uses default settings to search for headers and libraries.

Description

This option specifies the root directory where headers and libraries are located.

For example, if the headers and libraries are normally located in `/usr/include` and `/usr/lib` respectively, `--sysroot=/mydir` will cause the compiler to search in `/mydir/usr/include` and `/mydir/usr/lib` for the headers and libraries.

IDE Equivalent

None

Alternate Options

None

`print-sysroot` compiler option

Tf

Tells the compiler to compile the file as a Fortran source file.

Syntax

Linux OS and macOS:

`-Tf` *`filename`*

Windows OS:

`/Tf` *`filename`*

Arguments

`filename` Is the name of the file.

Default

OFF Files that do not end in standard Fortran file extensions are not compiled as Fortran files.

Description

This option tells the compiler to compile the file as a Fortran source file.

This option is useful when you have a Fortran file with a nonstandard file extension (that is, not one of .F, .FOR, or .F90).

This option assumes the file specified uses fixed source form. If the file uses free source form, you must also specify option `free`.

IDE Equivalent

None

Alternate Options

None

See Also

`extfor` compiler option

`free` compiler option

watch

Tells the compiler to display certain information to the console output window.

Syntax

Linux OS:

`-watch[=keyword[, keyword...]]`

`-nowatch`

macOS:

`-watch[=keyword[, keyword...]]`

`-nowatch`

Windows OS:

`/watch[:keyword[, keyword...]]`

`/nowatch`

Arguments

keyword Determines what information is displayed. Possible values are:

`none`	Disables `cmd` and `source`.
`[no]cmd`	Determines whether driver tool commands are displayed and executed.
`[no]source`	Determines whether the name of the file being compiled is displayed.
`all`	Enables `cmd` and `source`.

Default

`nowatch` Pass information and source file names are not displayed to the console output window.

Description

Tells the compiler to display processing information (pass information and source file names) to the console output window.

Option **watch***keyword*	Description
`none`	Tells the compiler to not display pass information and source file names to the console output window. This is the same as specifying `nowatch`.
`cmd`	Tells the compiler to display and execute driver tool commands.
`source`	Tells the compiler to display the name of the file being compiled.
`all`	Tells the compiler to display pass information and source file names to the console output window. This is the same as specifying `watch` with no *keyword*. For heterogeneous compilation, the tool commands for the host and the offload compilations will be displayed.

IDE Equivalent

None

Alternate Options

`watch cmd` Linux and macOS*: `-v`

Windows: None

See Also

`v` compiler option

what

Tells the compiler to display its detailed version string.

Syntax

Linux OS and macOS:

`-what`

Windows OS:

`/what`

Arguments

None

Default

OFF The version strings are not displayed.

Description

This option tells the compiler to display its detailed version string.

IDE Equivalent

None

Alternate Options

None

Alternate Compiler Options

This topic lists alternate names for compiler options and show the primary option name. Some of the alternate option names are deprecated and may be removed in future releases.

For more information on compiler options, see the detailed descriptions of the individual, primary options.

Some of these options are deprecated. For more information, see Deprecated and Removed Options.

Floating-Point Operations

Understanding Floating-Point Operations

Programming Tradeoffs in Floating-Point Applications

In general, the programming objectives for floating-point applications fall into the following categories:

- **Accuracy:** The application produces results that are close to the correct result.
- **Reproducibility and portability:** The application produces consistent results across different runs, different sets of build options, different compilers, different platforms, and different architectures.
- **Performance:** The application produces fast, efficient code.

Based on the goal of an application, you will need to make tradeoffs among these objectives. For example, if you are developing a 3D graphics engine, performance may be the most important factor to consider, with reproducibility and accuracy as secondary concerns.

The Intel® Fortran Compiler provides several compiler options that allow you to tune your applications based on specific objectives. Broadly speaking, there are the floating-point specific options, such as the `-fp-model` (Linux* and macOS*) or `/fp` (Windows*) option, and the fast-but-low-accuracy options, such as the `[Q]imf-max-error` option. The compiler optimizes and generates code differently when you specify these different compiler options. Select appropriate compiler options by carefully balancing your programming objectives and making tradeoffs among these objectives. Some of these options may influence the choice of math routines that are invoked.

Many routines in the *libirc*, *libm*, and *svml* library are more highly optimized for Intel microprocessors than for non-Intel microprocessors.

Using Floating-Point Options

Take the following code as an example:

Example

```
REAL(4):: t0, t1, t2
 ...
t0=t1+t2+4.0+0.1
```

If you specify the `-fp-model extended` (Linux* and macOS*) or `/fp:extended` (Windows*) option in favor of accuracy, the compiler generates the following assembly code:

```
fld       DWORD PTR _t1
fadd      DWORD PTR _t2
fadd      DWORD PTR _Cnst4.0
fadd      DWORD PTR _Cnst0.1
fstp      DWORD PTR _t0
```

This code maximizes accuracy because it utilizes the highest mantissa precision available on the target platform. The code performance might suffer when managing the x87 stack, and it might yield results that cannot be reproduced on other platforms that do not have an equivalent extended precision type.

If you specify the `-fp-model source` (Linux* and macOS*) or `/fp:source` (Windows*) option in favor of reproducibility and portability, the compiler generates the following assembly code:

```
movss     xmm0, DWORD PTR _t1
addss     xmm0, DWORD PTR _t2
addss     xmm0, DWORD PTR _Cnst4.0
addss     xmm0, DWORD PTR _Cnst0.1
movss     DWORD PTR _t0, xmm0
```

This code maximizes portability by preserving the original order of the computation, and by using the IEEE single-precision type for all computations. It is not as accurate as the previous implementation, because the intermediate rounding error is greater compared to extended precision. It is not the highest performance implementation, because it does not take advantage of the opportunity to pre-compute `4.0 + 0.1`.

If you specify the `-fp-model fast` (Linux* and macOS*) or `/fp:fast` (Windows*) option in favor of performance, the compiler generates the following assembly code:

```
movss     xmm0, DWORD PTR _Cnst4.1
addss     xmm0, DWORD PTR _t1
addss     xmm0, DWORD PTR _t2
movss     DWORD PTR _t0, xmm0
```

This code maximizes performance using Intel® Streaming SIMD Extensions (Intel® SSE) instructions and pre-computing `4.0 + 0.1`. It is not as accurate as the first implementation, due to the greater intermediate rounding error. It does not provide reproducible results like the second implementation, because it must reorder the addition to pre-compute `4.0 + 0.1`. All compilers, on all platforms, at all optimization levels do not reorder the addition in the same way.

For many other applications, the considerations may be more complicated.

Using Fast-But-Low-Accuracy Options

The fast-but-low-accuracy options provide an easy way to control the accuracy of mathematical functions and utilize performance/accuracy tradeoffs offered by the Intel® Math Kernel Library (Intel® MKL). You can specify accuracy, via a command line interface, for all math functions or a selected set of math functions at the level more precise than low, medium, or high.

You specify the accuracy requirements as a set of function attributes that the compiler uses for selecting an appropriate function implementation in the math libraries. Examples using the attribute, `max-error`, are presented here. For example, use the following option to specify the relative error of two ULPs for all single, double, long double, and quad precision functions:

```
-fimf-max-error=2
```

To specify twelve bits of accuracy for a `sin` function, use:

```
-fimf-accuracy-bits=12:sin
```

To specify relative error of ten ULPs for a `sin` function, and four ULPs for other math functions called in the source file you are compiling, use:

```
-fimf-max-error=10:sin-fimf-max-error=4
```

On Windows systems, the Intel® Fortran Compiler defines the default value for the `max-error` attribute depending on the `/fp` option and `/Qfast-transcendentals` settings. In `/fp:fast` mode, or if fast but less accurate math functions are explicitly enabled by `/Qfast-transcendentals-`, then the Intel® Fortran Compiler sets a `max-error=4.0` for the call. Otherwise, it sets a `max-error=0.6`.

Dispatching of Math Routines

The Intel® Fortran Compiler optimizes calls to routines from the *libm* and *svml* libraries into direct CPU-specific calls, when the compilation configuration specifies the target CPU where the code is tuned, and if the set of instructions available for the code compilation is not narrower than the set of instructions available in the tuning target CPU.

For example:

- The code containing calls to the *EXP()* library function and compiled with `-mtune=corei7-avx` (specifies tuning target CPU that supports Intel® Advanced Vector Extensions (Intel® AVX)) and `-QxCORE-AVX2/-march=core-avx2` (specifies Intel® Advanced Vector Extensions 2 (Intel® AVX2) instructions set) call the *EXP()* routine that is optimized for processors with Intel® AVX support. This code provides the best performance for these processors.
- The same code, compiled with `-mtune=core-avx2` and `-QxAVX/-march=corei7-avx`, calls a library dispatch routine that picks the optimal CPU specific version of the *EXP()* routine in runtime. Dispatching cannot be avoided because the instruction set does not allow the use of Intel® AVX2. Dynamic dispatching provides the best performance with the Intel® AVX2 CPU.

The dispatching optimization applies to the *EXP()* routine, and to the other math routines with CPU specific implementations in the libraries. The dispatching optimization can be disabled using the `-fimf-force-dynamic-target` (or Qimf-force-dynamic-target) option. This option specifies a list of math routines that are improved with a dynamic dispatcher. (See the Intel® Fortran Compiler documentation for syntax examples.)

Using -fp-model(/fp) Options

`fimf-max-error, Qimf-max-error` compiler option

Floating-point Optimizations

Application performance is an important goal of the Intel® Fortran Compiler, even at default optimization levels. A number of optimizations involve transformations that might affect the floating-point behavior of the application, such as evaluation of constant expressions at compile time, hoisting invariant expressions out of loops, or changes in the order of evaluation of expressions. These optimizations usually help the compiler to produce the most efficient code possible. However, the optimizations might be contrary to the floating-point requirements of the application.

Some optimizations are not consistent with strict interpretation of the ANSI or ISO standards for Fortran. Such optimizations can cause differences in rounding and small variations in floating-point results that may be more or less accurate than the ANSI-conformant result.

The Intel® Fortran Compiler provides the `-fp-model` (Linux* and macOS*) or `/fp` (Windows*) option, which allows you to control the optimizations performed when you build an application. The option allows you to specify the compiler rules for:

- **Value safety:** Whether the compiler may perform transformations that could affect the result. For example, in the SAFE mode, the compiler won't transform `x/x` to 1.0 because the value of `x` at runtime might be a zero or a NaN . The UNSAFE mode is the default.
- **Floating-point expression evaluation:** How the compiler should handle the rounding of intermediate expressions.
- **Floating-point contractions:** Whether the compiler should generate fused multiply-add (FMA) instructions on processors that support them. When enabled, the compiler may generate FMA instructions for combining multiply and add operations; when disabled, the compiler must generate separate multiply and add instructions with intermediate rounding.
- **Floating-point environment access:** Whether the compiler must account for the possibility that the program might access the floating-point environment, either by changing the default floating-point control settings or by reading the floating-point status flags. This is disabled by default. You can use the `-fp-model:strict` (Linux* and macOS*) `/fp:strict` (Windows*) option to enable it.

- **Precise floating-point exceptions:** Whether the compiler should account for the possibility that floating-point operations might produce an exception. This is disabled by default. You can use `-fp-model:strict` (Linux* and macOS*) or `/fp:strict` (Windows*); or `-fp-model:except` (Linux* and macOS*) or `/fp:except` (Windows*) to enable it.

The following table describes the impact of different keywords of the option on compiler rules and optimizations:

Keyword	Value Safety	Floating-Point Expression Evaluation	Floating-Point Contractions	Floating-Point Environment Access	Precise Floating-Point Exceptions
`precise` `source`	Safe	Source Source	Yes	No	No
`strict`	Safe	Source	No	Yes	Yes
`consistent`	Safe	Source	No	No	No
`fast=1` (default)	Unsafe	Unknown	Yes	No	No
`fast=2`	Very unsafe	Unknown	Yes	No	No
`except` `except-`	Unaffected Unaffected	Unaffected Unaffected	Unaffected Unaffected	Unaffected Unaffected	Yes No

NOTE
It is illegal to specify the `except` keyword in an unsafe safety mode.

Based on the objectives of an application, you can choose to use different sets of compiler options and keywords to enable or disable certain optimizations, so that you can get the desired result.

See Also
Using -fp-model (/fp) Option

Using the -fp-model (/fp) Option

The `-fp-model` (Linux* and macOS*) or `/fp` (Windows*) option allows you to control the optimizations on floating-point data. You can use this option to tune the performance, level of accuracy, or result consistency for floating-point applications across platforms and optimization levels.

For applications that do not require support for subnormal numbers, the `-fp-model` or `/fp` option can be combined with the `[Q]ftz` option to flush subnormal results to zero in order to obtain improved runtime performance on processors based on all Intel® architectures.

You can use keywords to specify the semantics to be used. The keywords specified for this option may influence the choice of math routines that are invoked. Many routines in the *libirc*, *libm*, and *libsvml* libraries are more highly optimized for Intel microprocessors than for non-Intel microprocessors. Possible values of the keywords are as follows:

Keyword	Description
`precise`	Enables value-safe optimizations on floating-point data and rounds intermediate results to source-defined precision.
`fast[=1|2]`	Enables more aggressive optimizations on floating-point data.

Keyword	Description
`consistent`	Enables consistent, reproducible results for different optimization levels or between different processors of the same architecture. This setting is equivalent to the use of the following options: Windows*: `/fp:precise /Qfma- /Qimf-arch-consistency:true` Linux* and macOS*: `-fp-model precise -no-fma -fimf-arch-consistency=true`
`strict`	Enables `precise` and `except`, disables contractions, and enables the property that allows modification of the floating-point environment.
`source`	Enables value-safe optimizations on floating-point data and rounds intermediate results to source-defined precision (same as precise keyword).
`[no-]except` (Linux* and macOS*) or `except[-]` (Windows*)	Determines whether strict floating-point exception semantics are used.

The default value of the option is `-fp-model fast=1` or `/fp:fast=1`, which means that the compiler uses more aggressive optimizations on floating-point calculations.

NOTE
Using the default option keyword `-fp-model fast` or `/fp:fast`, you may get significant differences in your result depending on whether the compiler uses x87 or SSE/AVX instructions to implement floating-point operations. Results are more consistent when the other option keywords are used.

Several examples are provided to illustrate the usage of the keywords. These examples show:

- A small example of source code.

NOTE
The same source code is considered in all the included examples.

- The semantics that are used to interpret floating-point calculations in the source code.
- One or more possible ways the compiler may interpret the source code.

NOTE
There are several ways the compiler may interpret the code; we show just some of these possibilities.

-fp-model fast or /fp:fast

Example source code:

Example

```
REAL T0, T1, T2;
...
T0 = 4.0E + 0.1E + T1 + T2;
```

When this option is specified, the compiler applies the following semantics:

- Additions may be performed in any order.
- Intermediate expressions may use `single, double,` or `extended double` precision.

- The constant addition may be pre-computed, assuming the default rounding mode.

Using these semantics, some possible ways the compiler may interpret the original code are given below:

Example

```
REAL T0, T1, T2;
  ...
T0 = (T1 + T2) + 4.1E;
```

```
REAL T0, T1, T2;
  ...
T0 = (T1 + 4.1E) + T2;
```

Subnormal Numbers

A normalized number is a number for which both the exponent (including bias) and the most significant bit of the mantissa are non-zero. For such numbers, all the bits of the mantissa contribute to the precision of the representation.

The smallest normalized single-precision floating-point number greater than zero is about 1.1754943^{-38}. Smaller numbers are possible, but those numbers must be represented with a zero exponent and a mantissa whose leading bit(s) are zero, which leads to a loss of precision. These numbers are called subnormal numbers or subnormals(older specifications refer to these as denormal numbers).

Subnormal computations use hardware and/or operating system resources to handle denormals; these can cost hundreds of clock cycles. Subnormal computations take much longer to calculate than normal computations.

There are several ways to avoid subnormals and increase the performance of your application:

- Scale the values into the normalized range.
- Use a higher precision data type with a larger range.
- Flush subnormals to zero.

Institute of Electrical and Electronics Engineers, Inc*. (IEEE) web site for information about the current floating-point standards and recommendations

Floating-Point Environment

The floating-point environment is a collection of registers that control the behavior of the floating-point machine instructions and indicate the current floating-point status. The floating-point environment can include rounding mode controls, exception masks, flush-to-zero (`FTZ`) controls, exception status flags, and other floating-point related features.

For example, bit 15 of the `MXCSR` register enables the flush-to-zero mode, which controls the masked response to an single-instruction multiple-data (SIMD) floating-point underflow condition.

The floating-point environment affects most floating-point operations; therefore, correct configuration to meet your specific needs is important. For example, the exception mask bits define which exceptional conditions will be raised as exceptions by the processor. In general, the default floating-point environment is set by the operating system. You don't need to configure the floating-point environment unless the default floating-point environment does not suit your needs.

There are several methods available if you want to modify the default floating-point environment. For example, you can use inline assembly, compiler built-in functions, library functions, or command line options.

Changing the default floating-point environment affects runtime results only. This does not affect any calculations that are pre-computed at compile time.

Setting the FTZ and DAZ Flags

In Intel® processors, the flush-to-zero (`FTZ`) and subnormals-are-zero (`DAZ`) flags in the `MXCSR` register are used to control floating-point calculations. Intel® Streaming SIMD Extensions (Intel® SSE) and Intel® Advanced Vector Extensions (Intel® AVX) instructions, including scalar and vector instructions, benefit from enabling the `FTZ` and `DAZ` flags. Floating-point computations using the Intel® SSE and Intel® AVX instructions are accelerated when the `FTZ` and `DAZ` flags are enabled. This improves the application's performance.

Use the `[Q]ftz` option to flush subnormal results to zero when the application is in the gradual underflow mode. This option may improve performance if the subnormal values are not critical to the application's behavior. The `[Q]ftz` option, when applied to the main program, sets the `FTZ` and the `DAZ` hardware flags. The negative forms of the `[Q]ftz` option (`-no-ftz` for Linux* and macOS*, and `/Qftz-` for Windows*) leave the flags as they are.

The following table describes how the compiler processes subnormal values based on the status of the `FTZ` and `DAZ` flags:

Flag	When set to ON, the compiler...	When set to OFF, the compiler...	Supported on
`FTZ`	...sets subnormal results from floating-point calculations to zero.	...does not change the subnormal results.	Intel® 64 and some IA-32 architectures
`DAZ`	...treats subnormal values used as input to floating-point instructions as zero.	...does not change the subnormal instruction inputs.	Intel® 64 and some IA-32 architectures

- `FTZ` and `DAZ` are not supported on all IA-32 architectures. The `FTZ` flag is supported only on IA-32 architectures that support Intel® SSE instructions.
- On systems based on the IA-32 and Intel® 64 architectures, `FTZ` only applies to Intel® SSE and Intel® AVX instructions. If the application generates subnormals using x87 instructions, `FTZ` does not apply.
- `DAZ` and `FTZ` flags are not compatible with the IEEE 754 standard, and should only be enabled when compliance to the IEEE standard is not required.

Options for `[Q]ftz` are performance options. Setting these options does not guarantee that all subnormals in a program are flushed to zero. They only cause subnormals generated at run-time to be flushed to zero.

On Intel® 64 and IA-32 systems, the compiler, by default, inserts code into the main routine to set the `FTZ` and `DAZ` flags. When the `[Q]ftz` option is used on IA-32 systems with the option `-msse2` or `/arch:sse2`, the compiler inserts code to that conditionally sets the `FTZ`/`DAZ` flags based on a run-time processor check. Using the negative form of `[Q]ftz` prevents the compiler from inserting any code that sets `FTZ` or `DAZ` flags.

When the `[Q]ftz` option is used in combination with an Intel® SSE-enabling option on systems based on the IA-32 architecture (for example, `-msse2` or `/arch:sse2`), the compiler inserts code in the main routine to set `FTZ` and `DAZ`. When the option `[Q]ftz` is used without an Intel® SSE-enabling option, the compiler inserts code that conditionally sets `FTZ` or `DAZ` based on a run-time processor check. The negative form of `[Q]ftz` prevents the compiler from inserting any code that might set `FTZ` or `DAZ`.

The `[Q]ftz` option only has an effect when the main program is being compiled. It sets the `FTZ`/`DAZ` mode for the process. The initial thread, and any subsequently created threads, operate in the `FTZ`/`DAZ` mode.

On systems based on Intel® 64 and IA-32 architectures, every optimization option `O` level, except `O0`, sets `[Q]ftz`.

If this option produces undesirable results of the numerical behavior of the program, turn the FTZ/DAZ mode off by using the negative form of [Q]ftz in the command line while still benefitting from the O3 optimizations.

Manually set the flags by calling the following Intel® Fortran intrinsic:

Example
`RESULT = FOR_SET_FPE (FOR_M_ABRUPT_UND)`

Checking the Floating-point Stack State

On systems based on the IA-32 architecture, when an application calls a function that returns a floating-point value, the returned floating-point value is supposed to be on the top of the floating-point stack. If the return value is not used, the compiler must pop the value off of the floating-point stack in order to keep the floating-point stack in the correct state.

On systems based on Intel® 64 architecture, floating-point values are usually returned in the xmm0 register. The floating-point stack is used only when the return value is an internal 80-bit floating-point data type on Linux* and macOS* systems.

If the application calls a function without defining or incorrectly defining the function's prototype, the compiler cannot determine if the function must return a floating-point value. Consequently, the return value is not popped off the floating-point stack if it is not used. This can cause the floating-point stack to overflow.

The overflow of the stack results in two undesirable situations:

- A NaN value gets involved in the floating-point calculations
- The program results become unpredictable; the point where the program starts making errors can be arbitrarily far away from the point of the actual error.

For systems based on the IA-32 and Intel® 64 architectures, the [Q]fp-stack-check option checks whether a program makes a correct call to a function that should return a floating-point value. If an incorrect call is detected, the option places a code that marks the incorrect call in the program. The [Q]fp-stack-check option marks the incorrect call and makes it easy to find the error.

> **NOTE**
> The [Q]fp-stack-check option causes significant code generation after every function/subroutine call to ensure that the floating-point stack is maintained in the correct state. Therefore, using this option slows down the program being compiled. Use the option only as a debugging aid to find floating point stack underflow/overflow problems, which can be otherwise hard to find.

Tuning Performance

Overview: Tuning Performance

This section describes several programming guidelines that can help you improve the performance of floating-point applications:

- Avoid exceeding representable ranges during computation; handling these cases can have a performance impact.

- Use REAL variables in single precision format unless the extra precision obtained through `DOUBLE` or `REAL*8` is required because a larger precision formation will also increase memory size and bandwidth requirements. See Using Efficient Data Types section.
- Reduce the impact of subnormal exceptions for all supported architectures.
- Avoid mixed data type arithmetic expressions.

Reducing the Impact of Subnormal Exceptions
Using Efficient Data Types

Handling Floating-point Array Operations in a Loop Body

Following the guidelines below will help auto-vectorization of the loop.

- Statements within the loop body may contain float or double operations (typically on arrays). The following arithmetic operations are supported: addition, subtraction, multiplication, division, negation, square root, `MAX`, `MIN`, and mathematical functions such as `SIN` and `COS`.
- Writing to a single-precision scalar/array and a double scalar/array within the same loop decreases the chance of auto-vectorization due to the differences in the vector length (that is, the number of elements in the vector register) between float and double types. If auto-vectorization fails, try to avoid using mixed data types.

See Also

Programming Guidelines for Vectorization

Reducing the Impact of Subnormal Exceptions

Subnormal floating-point values are those that are too small to be represented in the normal manner; that is, the mantissa cannot be left-justified. Subnormal values require hardware or operating system interventions to handle the computation, so floating-point computations that result in subnormal values may have an adverse impact on performance.

There are several ways to handle subnormals to increase the performance of your application:

- Scale the values into the normalized range
- Use a higher precision data type with a larger range
- Flush subnormals to zero

For example, you can translate them to normalized numbers by multiplying them using a large scalar number, doing the remaining computations in the normal space, then scaling back down to the subnormal range. Consider using this method when the small subnormal values benefit the program design.

If you change the type declaration of a variable, you might also need to change associated library calls, unless these are generic; . Another strategy that might result in increased performance is to increase the amount of precision of intermediate values using the `-fp-model [double|extended]` option. However, this strategy might not eliminate all subnormal exceptions, so you must experiment with the performance of your application. You should verify that the gain in performance from eliminating subnormals is greater than the overhead of using a data type with higher precision and greater dynamic range.

In many cases, subnormal numbers can be treated safely as zero without adverse effects on program results. Depending on the target architecture, use flush-to-zero (`FTZ`) options.

IA-32 and Intel® 64 Architectures

These architectures take advantage of the `FTZ` (flush-to-zero) and `DAZ` (subnormals-are-zero) capabilities of Intel® Streaming SIMD Extensions (Intel® SSE) instructions.

By default, the Intel® Fortran Compiler inserts code into the main routine to enable `FTZ` and `DAZ` at optimization levels higher than `O0`. To enable `FTZ` and `DAZ` at `O0`, compile the source file containing PROGRAM using compiler option `[Q]ftz`. When the `[Q]ftz` option is used on IA-32-based systems with the option `-mia32` (Linux*) or `/arch:IA32` (Windows*), the compiler inserts code to conditionally enable `FTZ` and `DAZ` flags based on a run-time processor check. IA-32 is not available on macOS*.

NOTE
After using flush-to-zero, ensure that your program still gives correct results when treating subnormal values as zero.

Avoiding Mixed Data Type Arithmetic Expressions

Avoid mixing integer and floating-point (REAL) data in the same computation. Expressing all numbers in a floating-point arithmetic expression (assignment statement) as floating-point values eliminates the need to convert data between fixed and floating-point formats. Expressing all numbers in an integer arithmetic expression as integer values also achieves this. This improves run-time performance.

For example, assuming that `I` and `J` are both INTEGER variables, expressing a constant number (2.0) as an integer value (2) eliminates the need to convert the data. The following examples demonstrate inefficient and efficient code.

Examples

Inefficient Code Example

```
INTEGER I, J
  I = J / 2.0
```

Efficient Code Example

```
INTEGER I, J
  I = J / 2
```

Special Considerations for Auto-Vectorization of the Innermost Loops

Auto-vectorization of an innermost loop packs multiple data elements from consecutive loop iterations into a vector register, each of which is 128-bit (SSE) or 256 bit (AVX) in size.

Consider a loop that uses different sized data, for example, REAL and DOUBLE PRECISION. For REAL data, the compiler tries to pack data elements from four (SSE) or eight (AVX) consecutive iterations (32 bits x 4 = 128 bits, 32 bits x 8 = 256 bits). For DOUBLE PRECISION data, the compiler tries to pack data elements from two (SSE) or four (AVX) consecutive iterations (64 bits x 2 = 128 bits, 64 bits x 4 = 256 bits). Because of the mismatched number of iterations, the compiler sometimes fails to perform auto-vectorization of the loop, after trying to automatically remedy the situation.

If your attempt to auto-vectorize an innermost loop fails, it is a good practice to try using the same sized data. INTEGER and REAL are considered same sized data since both are 32-bit in size.

Examples

Example 1: Not auto-vectorizable code

```
DOUBLE PRECISION A(N), B(N)
REAL C(N), D(N)
DO I=1, N
   A(I)=D(I)
   C(I)=B(I)
ENDDO
```

Example 2: Auto-vectorizable after automatic distribution into two loops

```
DOUBLE PRECISION A(N), B(N)
REAL C(N), D(N)
DO I=1, N
   A(I)=B(I)
   C(I)=D(I)
ENDDO
```

Example 3: Auto-vectorizable as one loop

```
REAL A(N), B(N)
REAL C(N), D(N)
DO I=1, N
   A(I)=B(I)
   C(I)=D(I)
ENDDO
```

Using Efficient Data Types

In cases where more than one data type can be used for a variable, consider selecting the data types based on the following hierarchy, listed from most to least efficient:

- Integer
- Single-precision real, expressed explicitly as `REAL`, `REAL (KIND=4)`, or `REAL*4`
- Double-precision real, expressed explicitly as `DOUBLE PRECISION`, `REAL (KIND=8)`, or `REAL*8`
- Extended-precision real, expressed explicitly as `REAL (KIND=16)` or `REAL*16`

NOTE
In an arithmetic expression, you should avoid mixing integer and floating-point data.

Libraries

Creating Static Libraries

Executables generated using static libraries are no different than executables generated from individual source or object files. Because static libraries are not required at runtime, you do not need to include them when you distribute your executable. Linking to a static library is generally faster than linking to individual object files.

When building objects for a static library from the `ifort` command line, include option `c` to suppress linking. Without this option, the linker will run and generate an error because the object is not a complete program.

Building a static library (Linux*)

1. Use the `c` option to generate object files from the source files:

```
ifort -c my_source1.f90 my_source2.f90 my_source3.f90
```

2. Use the Intel® `xiar` tool to create the library file from the object files:

```
xiar rc my_lib.a my_source1.o my_source2.o my_source3.o
```

3. Compile and link your project with your new library:

```
ifort main.f90 my_lib.a
```

If your library file and source files are in different directories, use the `-Ldir` option to indicate where your library is located:

```
ifort -L/for/libs main.f90 my_lib.a
```

Building a static library (macOS*)

1. Use the following command line to generate object files and create the library file:

```
ifort -o my_lib.a -staticlib mysource1.f90 mysource2.f90 mysource3.f90
```

2. Compile and link your project with your new library:

```
ifort main.f90 my_lib.a
```

If your library file and source files are in different directories, use the `-Ldir` option to indicate where your library is located:

```
ifort -L/for/libs main.f90 my_lib.a
```

Building a static library (Windows*)

To build a static library from the integrated development environment (IDE), select the **Fortran Static Library** project type.

To build a static library using the command line:

1. Use option `c` to generate object files from the source files:

```
ifort /c my_source1.f90 my_source2.f90
```

2. Use the Intel® `xilib` tool to create the library file from the object files:

```
xilib /out:my_lib.lib my_source1.obj my_source2.obj
```

3. Compile and link your project with your new library:

```
ifort main.f90 my_lib.lib
```

Creating Shared Libraries

This topic applies to Linux* and macOS*.

Shared libraries, also referred to as dynamic libraries, are linked differently than static libraries. At compile time, the linker insures that all the necessary symbols are either linked into the executable, or can be linked at runtime from the shared library. Executables compiled from shared libraries are smaller, but the shared libraries must be included with the executable to function correctly. When multiple programs use the same shared library, only one copy of the library is required in memory.

To create a shared library from a Fortran source file, process the files using the `ifort` command:

- You must specify the `-shared` option (Linux*) or the `-dynamiclib` option (macOS*) to create the `.so` or `.dylib` file. On Linux* and macOS* operating systems using either IA-32 architecture or Intel® 64 architecture, you must also specify option `-fpic` for the compilation of each object file you want to include in the shared library.
- You can specify the `-o`*output* option to name the output file.
- If you omit the `-c` option, you will create a shared library (`.so` file) directly from the command line in a single step.
- If you also omit the `-o`*output* option, the file name of the first Fortran file on the command line is used to create the file name of the `.so` file. You can specify additional options associated with shared library creation.
- If you specify the `-c` option, you will create an object file (`.o` file) that you can name with the `-o` option. To create a shared library, process the `.o` file with `ld` , specifying certain options associated with shared library creation.

Creating a Shared Library

There are several ways to create a shared library.

You can create a shared library file with a single `ifort` command:

```
ifort -shared -fpic octagon.f90 (Linux*)
ifort -dynamiclib octagon.f90 (macOS*)
```

The `-shared` or `-dynamiclib` option is required to create a shared library. The name of the source file is `octagon.f90`. You can specify multiple source files and object files.

Because the `-o` option was omitted, the name of the shared library file is `octagon.so` (Linux*) or `octagon.dylib` (macOS*).

You can use the `-static-intel` option to force the linker to use the static versions of the Intel-supplied libraries.

You can also create a shared library file with a combination of `ifort` and `ld` (Linux*) or `libtool` (macOS*) commands:

First, create the `.o` file, such as `octagon.o` in the following example:

```
ifort -c -fpic octagon.f90
```

The file `octagon.o` is then used as input to the `ld` (Linux*) or `libtool` (macOS*) command to create the shared library. The following example shows the command to create a shared library named `octagon.so` on a Linux* operating system:

```
ld -shared octagon.o \
     -lifport -lifcoremt -limf -lm -lcxa \
     -lpthread -lirc -lunwind -lc -lirc_s
```

Note the following:

- When you use `ld`, you need to list all Intel® Fortran libraries. It is easier and safer to use the `ifort` command. On macOS*, you would use `libtool`.
- The `-shared` option is required to create a shared library. On macOS*, use the `-dynamiclib` option, and also specify the following: `-arch_only i386`, `-noall_load`, `-weak_references_mismatches non-weak`.
- The name of the object file is `octagon.o`. You can specify multiple object (`.o`) files.
- The `-lifport` option and subsequent options are the standard list of libraries that the `ifort` command would have otherwise passed to `ld` or `libtool`. When you create a shared library, all symbols must be resolved.

It is recommended that you review the output of the `-dryrun` command to find the names of all the libraries used, to be able to specify them correctly.

If you are using the `ifort` command to link, you can use the `-Qoption` command to pass options to the `ld` linker. (You cannot use `-Qoption` on the `ld` command line.)

For more information on relevant compiler options, see the Compiler Options reference.

See also the `ld(1)` reference page.

Shared Library Restrictions

When creating a shared library with `ld`, be aware of the following restrictions:

- Shared libraries must not be linked with archive libraries.

  When creating a shared library, you can only depend on other shared libraries for resolving external references. If you need to reference a routine that currently resides in an archive library, put that routine in a separate shared library or include it in the shared library being created. You can specify multiple object (`.o`) files when creating a shared library.

  To put a routine in a separate shared library, obtain the source or object file for that routine, recompile if necessary, and create a separate shared library. You can specify an object file when recompiling with the `ifort` command or when creating the shared library with the `ld` command.

  To include a routine in the shared library being created, put the routine (source or object file) with other source files that make up the shared library and recompile if necessary.

  Now create the shared library, and specify the file containing that routine either during recompilation or when creating the shared library. You can specify an object file when recompiling with the `ifort` command or when creating the shared library with the `ld` or `libtool` command.
- When creating shared libraries, all symbols must be defined (resolved).

  Because all symbols must be defined to `ld` when you create a shared library, you must specify the shared libraries on the `ld` command line, including all standard Intel® Fortran libraries. The list of standard Intel® Fortran libraries can be specified by using the `-l`*`string`* option.

Installing Shared Libraries

Once the shared library is created, it must be installed for private or system-wide use before you run a program that refers to it:

- To install a *private* shared library (when you are testing, for example), set the environment variable `LD_LIBRARY_PATH`, as described in `ld(1)`. For macOS*, set the environment variable `DYLD_LIBRARY_PATH`.
- To install a *system-wide* shared library, place the shared library file in one of the standard directory paths used by `ld` or `libtool`.

Using Shared Libraries on macOS*

On macOS*, it is possible to store path information in shared libraries to perform library searches. The compiler installation changes the path to the installation directory, but you will need to modify these paths if you move the libraries elsewhere. For example, you may want to bundle redistributable Intel libraries with your application, which eliminates the dependency on libraries found on `DYLD_LIBRARY_PATH`.

If your compilations do not use `DYLD_LIBRARY_PATH` to find libraries, and you distribute executables that depend on shared libraries, then you will need to modify the Intel shared libraries (`../lib/*.dylib`) using the `install_name_tool` to set the correct path to the shared libraries. This also permits the end-user to launch the application by double-clicking on the executable. The code below will modify each library with the correct absolute path information:

```
for i in *.dylib
do
echo -change $i `pwd`/$i
done > changes
for i in *.dylib
do
install_name_tool `cat changes` $i
done
```

You can also use the `install_name_tool` command to set `@executable_path` to change path information for the libraries bundled in your application by changing the path appropriately.

Be sure to recompile your sources after modifying the libraries.

Calling Library Routines

The following tables show Intel® Fortran library routine groups and the USE statement required to include the interface definitions for the routines in that group:

Routines	USE statement
Portability	USE IFPORT
POSIX*	USE IFPOSIX
Miscellaneous Run-Time	USE IFCORE

The following are Windows only:

Routines	USE statement
Automation (AUTO) (systems using IA-32 architecture only)	USE IFAUTO
Component Object Model (COM) (systems using IA-32 architecture only)	USE IFCOM
Dialog (systems using IA-32 architecture only)	USE IFLOGM
Graphics	USE IFQWIN
National Language Support	USE IFNLS
QuickWin	USE IFQWIN
Serial port I/O (SPORT)(systems using IA-32 architecture only)	USE IFPORT

Language Reference section *Run-Time Library Routines* lists topics that provide an overview of the different groups of library routines as well as calling syntax for the routines. For example, add the following USE statement before any data declaration statements, such as IMPLICIT, NONE, or INTEGER:

```
USE IFPORT
```

If you want to minimize compile time for source files that use the Intel® Fortran library routines, add the ONLY keyword to the USE statement. For example:

```
USE IFPORT, only: getenv
```

Using the ONLY keyword limits the number of interfaces for that group of library routines.

To view the actual interface definitions, view the `.f90` file that corresponds to the `.mod` file. For example, if a routine requires a `USE IFCORE`, locate and use a text editor to view the file `ifcore.f90` in the standard INCLUDE directory.

You should avoid copying the actual interface definitions contained in the `ifport.f90` (or `ifcore.f90`, ...) into your program because future versions of Intel® Fortran might change these interface definitions.

Similarly, some of the library interface `.f90` files contain `USE` statements for a subgrouping of routines. However, if you specify a USE statement for such a subgroup, this module name may change in future version of the Intel® Fortran compiler. Although this will make compilation times faster, it might not be compatible with future versions of the compiler.

Run-Time Library Routines

Comparison of Intel® Visual Fortran and Windows* API Routines

This topic only applies to Windows*.

Intel® Visual Fortran provides Fortran language elements (such as intrinsic procedures and statements) that conform to the Fortran Standard. The Intel® Visual Fortran Compiler also provides language elements that are language extensions, including library routines.

The library routines provided by the Intel® Visual Fortran Compiler:

- Are intended to be called from the Fortran language. For example, character arguments are assumed to be Fortran character variables, not null-terminated C strings.
- May have `QQ` appended at the end of their names to differentiate them from equivalent Windows* routines.
- Are described in the Intel® Visual Fortran Compiler *Language Reference* online documentation, in the A to Z Reference. The routine description lists the appropriate USE statement needed to include the interface definitions, such as USE IFPORT.
- Call appropriate Windows* system API routines provided with the operating system.
- Are specific to Windows* systems, with one exception: most of the Intel® Fortran IFPORT Portability Library routines exist on most Linux* systems.

In contrast, the Windows* API routines provided by the Windows* operating system:

- Are intended to be called from the C language. For example, character arguments are assumed to be null-terminated C strings.
- Often have multiple words appended together in their names, such as `GetSystemTime`.
- Are described in the Windows* SDK online documentation. To look up a specific routine, visit the MSDN Library website. The calling format is listed near the top of the page, followed by a description of the routine's arguments. The QuickInfo at the bottom of the Windows* API routine documentation page lists the import library needed.
- Are also specific to Windows*.

Note that the Intel® Visual Fortran Compiler provides interface block definitions that simplify calling Windows* API routines from the Intel® Visual Fortran Compiler (such as allowing you to specify Fortran data arguments as being passed by reference). To obtain these interface definitions, add the USE IFWIN statement to your program.

There are many groups of Windows* routines (see the Platform SDK and other resources). These routines provide sophisticated window management, memory management, graphics support, threading, security, and networking.

You can access many Windows* API routines from any Fortran application, including Fortran Console and Fortran QuickWin applications. Only the Fortran Windows* application Understanding Project Types provides access to the full set of Win32 routines needed to create GUI applications.

Fortran Console applications are text-only applications. Fortran QuickWin applications allow you to build Windows*-style applications easily, but access only a small subset of the available Windows* API features. Fortran QuickWin applications also allow you to use graphics.

IFPORT Portability Library
Understanding Project Types

Specifying Consistent Library Types

This topic only applies to Windows*.

There are a number of Visual C++* run-time libraries that offer the same entry points but have different characteristics. The default Visual C++* library is `libc.lib`, which is single-threaded, non-debug, and static.

The Intel® Visual Fortran and Microsoft* Visual C++* libraries must be the same types. The incompatible types are listed below.

- Mixing single-threaded with multi-threaded versions of the libraries.
- Mixing static and dynamic-link versions of the libraries.
- Mixing debug with non-debug versions of the libraries.

The default Intel® Visual Fortran libraries depend on the project type:

Fortran Project Type	Default Libraries Used
Fortran Console	Static, single-threaded libraries `ifcore.lib` and `libc.lib`
Fortran Standard Graphics	Static, multithreaded libraries `ifcoremt.lib` and `libcmt.lib`
Fortran QuickWin	Static, multithreaded libraries `ifcoremt.lib` and `libcmt.lib`
Fortran Windows	Static, multithreaded libraries `ifcoremt.lib` and `libcmt.lib`
Fortran DLL	Dynamic-link libraries ifcoremd and msvcrt (and their import libraries)

Pure Fortran applications can have mismatched types of libraries. One common scenario is a Fortran QuickWin application that links with a Fortran Static library. Fortran QuickWin (and Fortran Standard Graphics) applications must use the static, multithreaded libraries, and by default, Fortran Static libraries are built using static, single-threaded libraries. Because this causes a conflict, the Fortran Static library and the QuickWin application must both be built using static, multithreaded libraries.

Similarly, different C/C++ applications link against different C libraries. If you mix the different types of applications without modifying the defaults, you can get conflicts. The debug version of a library has a letter *d* appended to its base file name:

- Static, multithreaded: `libcmt.lib` and `libcmtd.lib`
- Dynamic-link libraries: `msvcrt` and `msvcrtd` (`.lib` import library and `.dll`)

When using a **Debug** configuration, Visual C++* selects the debug libraries.

The Intel® Visual Fortran Compiler does not select debug libraries for any configuration, but provides settings that allow you to request their use. To specify different types of Fortran libraries in the IDE, select **Project** > **Properties**, then select the **Libraries category** on the **Fortran** tab:

- To specify static libraries, select the appropriate type of static (non-DLL) library under Run-Time Library (see `/libs:static`).
- To specify dynamic-link libraries, select the appropriate type of DLL library under Run-Time Library (see `/libs:dll`).

- To specify the debug libraries, select the appropriate type of Debug library under Run-Time Library (see `/[no]dbglibs`). If you specify debug libraries (`/dbglibs`) and also request DLL libraries (`/libs:dll`), be aware that this combination selects the debug versions of the Fortran DLLs. These Fortran DLL files have been linked against the C debug DLLs.
- When you specify QuickWin or Standard Graphics libraries under Run-Time Library, this selection implicitly requests multithreaded libraries.

> **NOTE** This option does not cause static linking of libraries for which no static version is available, such as the OpenMP run-time libraries on Windows* or the coarray run-time libraries. These libraries can only be linked dynamically.

Redistributing Libraries When Deploying Applications

When you deploy your application to systems that do not have the Intel® Fortran Compiler installed, you need to redistribute certain Intel® libraries to which your application is linked. You can do so in one of the following ways:

- Statically link your application.

  An application built with statically-linked libraries eliminates the need to distribute runtime libraries with the application executable. By linking the application to the static libraries, you are not dependent on the Intel® Fortran or Intel® C/C++ dynamic shared libraries.
- Dynamically link your application.

  If you must build your application with dynamically linked (or shared) compiler libraries, you should address the following concerns:

  - You must build your application with shared or dynamic libraries that are redistributable.
  - Note the directory where the redistributables are installed and how the OS finds them.
  - You should determine which shared or dynamic libraries your application needs.

The information here is only introductory. See the Intel® Developer Zone articles at https://software.intel.com (search for "redistributable libraries") for everything you need to know to redistribute these libraries.

The redistributable library installation package is available at: https://software.intel.com/en-us/articles/intelr-composer-redistributable-libraries-by-version

Storing Object Code in Static Libraries

Another way to organize source code used by several projects is to build a static library (for Windows*, `.lib` and for Linux* and macOS*, `.a`) containing the object files for the reused procedures. You can create a static library by doing the following:

- From the Microsoft* Visual Studio* integrated development environment (IDE), create and build a Fortran Static Library project type.

- From the command line, use the `xiar` command (on Linux* and macOS*) or the `xilib` command (Windows*).

After you have created a static library, you can use it as input to other types of Intel® Fortran Compiler projects.

Using Fortran Static Library Projects

Storing Routines in Shareable Libraries

You can organize the code in your application by storing the executable code for certain routines in a shareable library (`.dll` for Windows*, `.so` for Linux*, or `.dylib` for macOS*). You can then build your applications so that they call these routines from the shareable library.

When routines in a shareable library are called, the routines are loaded into memory at run-time as they are needed. This is most useful when several applications use a common group of routines. By storing these common routines in a shareable library, you reduce the size of each application that calls the library. In addition, you can update the routines in the library without having to rebuild any of the applications that call the library.

Using the Windows* API Routines

Including the Intel® Visual Fortran Interface Definitions for Windows* API Routines

This topic only applies to Windows*.

Intel® Fortran provides interface definitions for both the Intel Fortran library routines and most of the Windows* API routines in the standard include directory. Documentation on the Windows API can be found at msdn.microsoft.com.

To include the Windows API interface definitions, do one of the following:

1. Add the statement USE IFWIN to include all Windows API routine definitions.

   The USE IFWIN statement makes all parameters and interfaces for most Windows routines available to your Intel Fortran program. Any program or subprogram that uses the Windows features can include the statement USE IFWIN, which is needed in each subprogram that makes Windows API calls.

2. Add the USE statement before any declaration statements (such as IMPLICIT NONE or INTEGER). You can limit the type of parameters and interfaces for Windows applications to make compilation times faster. To do this, include only the subsets of the Windows API needed in multiple USE statements (see the file `...\INCLUDE\IFWIN.F90`).

   To locate the specific libraries for the routines being called, view the QuickInfo at the bottom of the routine page in the Windows API documentation at msdn.microsoft.com, which lists the import library name. For example, to call only GetSystemTime, you need the interface definitions provided in kernel32.mod (binary form). To do this, add the following USE statement:

```
USE KERNEL32
```

If you want to further minimize compile time, add the ONLY keyword to the USE statement. For example:

```
USE KERNEL32, only: GetSystemTime, GetLastError
```

Calling Windows API Routines

This topic describes general information about calling Windows API routines from Intel® Fortran applications. It contains the following information:

- Calling Windows API Routines Using the Intel® Visual Fortran Interface Definitions

- Understanding Data Types Differences

Calling Windows API Routines Using the Intel® Visual Fortran Interface Definitions

To call the appropriate Windows API routine after including the Intel® Visual Fortran interface definitions, follow these guidelines:

1. Examine the documentation for the appropriate routine in the Windows API (for example, GetSystemTime) to obtain the following information:
   - The number and order of arguments. You will need to declare and initialize each argument variable using the correct data type. In the case of the GetSystemTime routine, a structure (derived type) is passed by reference.

     If character arguments are present, add a null character as a terminator to the character variable before calling the Windows API routine.
   - Whether the routine returns a result (function) or not (subroutine). For example, because the GetSystemTime routine calling format starts with VOID, this routine should be called as a subroutine with a `CALL` statement.
2. If you are not sure about the data type of arguments or its function return value, you can examine the interface definitions in the appropriate .F90 file in `...\INCLUDE\`. For example, to view the interface definition for GetSystemTime:
   - In a text editor (such as Notepad), open the file kernel32.f90 from `...\INCLUDE\`.
   - Search (or Find) the routine name (such as GetSystemTime)
   - View the interface definition and compare it to the description in the Windows API documentation to see how the arguments are represented in Fortran. Take note of how arguments are passed; in some cases, such as when an arbitrary data type is passed by address, you must pass the address of a variable using the LOC intrinsic rather than the variable directly.
3. If one of the arguments is a structure, look up the definition in IFWINTY.F90 in `...\INCLUDE\`. For example, to view the data type definition for the T_SYSTEMTIME type used in GetSystemTime:
   - In a text editor (such as Notepad), open the file IFWINTY.F90 from `...\INCLUDE\`.
   - Search (or Find) the data type name (such as T_SYSTEMTIME).
   - View the data type definition and note the field names. In some cases, these will differ slightly from those listed in the Windows API documentation.
   - Define a variable name to use the derived-type definition in your program, such as:

```
TYPE (T_SYSTEMTIME) MYTIME
```

4. Many Windows API routines have an argument or return a value described as a "`handle`". This is generally an address-sized integer and must be declared using an appropriate `KIND` value, typically `HANDLE`, which automatically provides the correct value for 32- and 64-bit platforms. For example:

```
Integer(HANDLE) :: hwnd
```

Use the variable definition to call the Win32 routine. For example, the completed program follows:

```
! Getsystime.f90 file shows how to call a Windows API routine
! Since the only routine called is GetSystemTime, only include
! interface definitions from kernel32.mod instead of all modules
! included by ifwin.f90. Type definitions are defined in IFWINTY,
! which is used within KERNEL32.
PROGRAM Getsystime
USE KERNEL32
TYPE (T_SYSTEMTIME) MYTIME
CALL GetSystemTime(MYTIME)
WRITE (*,*) 'Current UTC time hour and minute:', Mytime.wHour, Mytime.Wminute
END PROGRAM
```

You can create a new Fortran Console (or QuickWin) application project, add the code shown above as a source file, build it, and view the result.

Understanding Data Type Differences

Module IFWINTY, which is used by IFWIN and the other Win32 API modules, defines a set of constants for INTEGER and REAL kinds that correspond to many of the type definitions provided in the Windows WINDOWS.H header file. Use these kind values in INTEGER and REAL declarations. The following table gives the correspondence of some of the more common Windows types:

Windows Data Type	Equivalent Fortran Data Type
BOOL, BOOLEAN	INTEGER(BOOL)
BYTE	INTEGER(BYTE)
CHAR, CCHAR, UCHAR	CHARACTER or INTEGER(UCHAR)
DWORD	INTEGER(DWORD)
ULONG	INTEGER(ULONG)
SHORT	INTEGER(SHORT)
LPHANDLE	INTEGER(LPHANDLE)
PLONG	INTEGER(PLONG)
DOUBLE	REAL(DOUBLE)

Use the kind constants instead of explicitly specifying the kind as a number, or assuming a default kind.

Note that the Windows BOOL type is not equivalent to Fortran LOGICAL and should not be used with Fortran LOGICAL operators and literal constants. Use the constants TRUE and FALSE, defined in IFWINTY, rather than the Fortran literals .TRUE. and .FALSE., and do not test BOOL values using LOGICAL expressions.

Additional notes about equivalent data types for arguments:

- If an argument is described in the Windows API documentation as a pointer, then the corresponding Fortran interface definition of that argument would have the REFERENCE property (see the ATTRIBUTES). Older interface definitions use the POINTER - Integer and pass the address of the argument, or the LOC intrinsic function.
- Pointer arguments on systems using IA-32 architecture are 32-bit (4 bytes) in length. Pointer arguments on systems using Intel® 64 architecture are 64 bits (8 bytes) in length.
- Be aware that Fortran character variables need to be null-terminated. You can do this by using the C string extension (see C Strings in Character Constants):

```
forstring = 'This is a null-terminated string.'C
```

  You can also concatenate a null using the C_NULL_CHAR constant from instrinsic module ISO_C_BINDING, or CHAR(0):

```
use, intrinsic :: ISO_C_BINDING
…
forstring = 'This is a null-terminated string'//C_NULL_CHAR
forstring2 = 'This is another null-terminated string'//CHAR(0)
```

The structures in WINDOWS.H have been converted to derived types in IFWINTY. Unions in structures are converted to union/maps within the derived type.

Names of components are generally unchanged. C bitfields do not translate directly to Fortran; collections of bitfields are declared as Fortran INTEGER types and individual bitfields are noted as comments in the source (IFWINTY.F90). To see how a particular Windows declaration was translated to Fortran, read the corresponding declaration in the appropriate .F90 source file in the Include folder.

Supplied Windows* API Modules

The Intel® Fortran Compiler provides the following Windows* API modules. These modules correspond to the Windows* import libraries of the same name.

ADVAPI32
COMCTL32
COMDLG32
GDI32
KERNEL32
LZ32
OLE32
OLEAUT32
PSAPI
SCRNSAVE
SHELL32
USER32
VERSION
WINMM
WINSPOOL
WS2_32
WSOCK32

Additionally, the `IFOPNGL` module declares OpenGL routines for Windows OS, with Fortran-specific names.

Math Libraries

The Intel® Fortran Compiler includes these math libraries:

Library name	Description
`libimf.a` (Linux* and macOS*)	Intel® Math Libraries, in addition to `libm.a`, the math library provided with gcc* Both of these libraries are linked in by default because certain math functions supported by the GNU* math library are not available in the Intel® Math Library. This linking arrangement allows the GNU* users to have all functions available when using `ifort`, with Intel optimized versions available when supported.

Library name	Description
	`libimf.a` is linked in before `libm.a`. If you link in `libm.a` first, it will change the versions of the math functions that are used. Many routines in the *libimf* library are more optimized for Intel® microprocessors than for non-Intel microprocessors.
`libm.lib` (static library) and `libmmd.dll` (the DLL version) (Windows*)	Math Libraries provided by Intel. Many routines in the *libimf* library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

NOTE
It is strongly recommended to use the default rounding mode (round-to-nearest-even) when calling math library transcendental functions and compiling with default optimization or higher. Faster implementations (in terms of latency and/or throughput) of these functions are validated under the default round-to-nearest-even mode. Using other rounding modes may make results generated by these faster implementations less accurate, or set unexpected floating-point status flags. This behavior may be avoided by `-no-fast-transcendentals`, which disables calls to the faster implementations of math functions, or by `-fp-model strict`, which warns the compiler that it cannot assume default settings for the floating-point environment.

Many routines in the Intel® Math Library are more optimized for Intel® microprocessors than for non-Intel microprocessors.

Intel® Math Kernel Library (Intel® MKL)	Math library of Fortran routines and functions that perform a wide variety of operations on vectors and matrices. The library also includes fast Fourier transform (fft) functions, as well as vector mathematical and vector statistical functions. For more information, see Using Intel® Performance Libraries with Microsoft Visual Studio* and the Intel® Math Kernel Library documentation.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Data and I/O

This section discusses the following:

- Fortran integer, logical, character, and Hollerith data representation
- Fortran input and output (I/O) topics, such as I/O devices, statements, and files, and OPEN and CLOSE statements

Data Representation Overview

Intel® Fortran expects numeric data to be in native little endian order, in which the least-significant, right-most zero bit (bit 0) or byte has a lower address than the most-significant, left-most bit (or byte). For information on using nonnative big endian and VAX* floating-point formats, see Supported Native and Nonnative Numeric Formats.

The symbol :A in any figure specifies the address of the byte containing bit 0, which is the starting address of the represented data element.

The following table lists the intrinsic data types used by Intel® Fortran, the storage required, and valid ranges. For information on declaring Fortran intrinsic data types, see Type Declarations. For example, the declaration INTEGER(4) is the same as INTEGER(KIND=4) and INTEGER*4.

Fortran Data Types and Storage

Data Type	Storage	Description
BYTE	1 byte (8 bits)	A signed integer data type equivalent to INTEGER(1).
INTEGER	See INTEGER(2), INTEGER(4), and INTEGER(8)	A signed integer, either INTEGER(2), INTEGER(4), or INTEGER(8). The size is controlled by the `integer-size` compiler option.
INTEGER(1)	1 byte (8 bits)	A signed integer value from -128 to 127.
INTEGER(2)	2 bytes (16 bits)	A signed integer value from -32,768 to 32,767.
INTEGER(4)	4 bytes (32 bits)	A signed integer value from -2,147,483,648 to 2,147,483,647.
INTEGER(8)	8 bytes (64 bits)	A signed integer value from -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807.
REAL	See REAL(4), REAL(8), and REAL(16)	A real floating-point value, either REAL(4), REAL(8), or REAL(16). The size is controlled by the `real-size` compiler option.
DOUBLE PRECISION	See REAL(8) and REAL(16)	A double precision floating-point value, either REAL(8) or REAL(16). The size is controlled by the `double-size` compiler option.
REAL(4)	4 bytes (32 bits)	A single-precision real floating-point value in IEEE binary32 format ranging from 1.17549435E-38 to 3.40282347E38. Values between 1.17549429E-38 and 1.40129846E-45 are subnormal.
REAL(8)	8 bytes (64 bits)	A double-precision real floating-point value in IEEE binary64 format ranging from 2.2250738585072013D-308 to 1.7976931348623158D308. Values between 2.2250738585072008D-308 and 4.94065645841246544D-324 are subnormal.
REAL(16)	16 bytes (128 bits)	An extended-precision real floating-point value in IEEE binary128 format ranging from 6.475175119438025110924438958227646552499 6Q-4966 to 1.189731495357231765085759326628007016196477Q4932.

Data Type	Storage	Description
COMPLEX	See COMPLEX(4), COMPLEX(8), and COMPLEX(16)	A complex floating-point value in a pair of real and imaginary parts that are either REAL(4), REAL(8), or REAL(16). The size is controlled by the `real-size` compiler option.
DOUBLE COMPLEX	See COMPLEX(8) and COMPLEX(16)	A double complex floating-point value in a pair of real and imaginary parts that are either REAL(8) or REAL(16). The size is controlled by the `double-size` compiler option.
COMPLEX(4)	8 bytes (64 bits)	A single-precision complex floating-point value in a pair of IEEE binary32 format parts: real and imaginary. The real and imaginary parts each range from 1.17549435E-38 to 3.40282347E38. Values between 1.17549429E-38 and 1.40129846E-45 are subnormal.
COMPLEX(8)	16 bytes (128 bits)	A double-precision complex floating-point value in a pair of IEEE binary64 format parts: real and imaginary. The real and imaginary parts each range from 2.2250738585072013D-308 to 1.7976931348623158D308. Values between 2.2250738585072008D-308 and 4.9406564584124654D-324 are subnormal.
COMPLEX(16)	32 bytes (256 bits)	An extended-precision complex floating-point value in a pair of IEEE binary128 format parts: real and imaginary. The real and imaginary parts each range from 6.475175119438025110924438958227646552499 6Q-4966 to 1.189731495357231765085759326628007016196477Q4932.
LOGICAL	See LOGICAL(2), LOGICAL(4), and LOGICAL(8)	A logical value, either LOGICAL(2), LOGICAL(4), or LOGICAL(8). The size is controlled by the `integer-size` compiler option.
LOGICAL(1)	1 byte (8 bits)	A logical value of .TRUE. or .FALSE.
LOGICAL(2)	2 bytes (16 bits)	A logical value of .TRUE. or .FALSE.
LOGICAL(4)	4 bytes (32 bits)	A logical value of .TRUE. or .FALSE.
LOGICAL(8)	8 bytes (64 bits)	A logical value of .TRUE. or .FALSE.
CHARACTER	1 byte (8 bits) per character	Character data represented by character code convention. Declarations for Character Types can be in the form CHARACTER(LEN=*n*) or CHARACTER**n*, where *n* is the number of bytes or *n* is (*) to indicate passed-length format.
HOLLERITH	1 byte (8 bits) per Hollerith character	A Hollerith constant.

In addition, you can define Binary Constants.

Integer Data Representations

The Fortran numeric environment is flexible, which helps make Fortran a strong language for intensive numerical calculations. The Fortran standard purposely leaves the precision of numeric quantities and the method of rounding numeric results unspecified. This allows Fortran to operate efficiently for diverse applications on diverse systems.

The effect of math computations on integers is straightforward:

- INTEGER(KIND=1) Representation consists of a maximum positive integer (127), a minimum negative integer (-128), and all integers between them including zero.
- INTEGER(KIND=2) Representation consisst of a maximum positive integer (32,767), a minimum negative integer (-32,768) , and all integers between them including zero.
- INTEGER(KIND=4) Representation consists of a maximum positive integer (2,147,483,647), a minimum negative integer (-2,147,483,648), and all integers between them including zero.
- INTEGER(KIND=8) Representation consists of a maximum positive integer (9,223,372,036,854,775,807), a minimum negative integer (-9,223,372,036,854,775,808), and all integers between them including zero.

Operations on integers usually result in other integers within this range. Integer computations that produce values too large or too small to be represented in the desired KIND result in the loss of precision. One arithmetic rule to remember is that integer division results in truncation (for example, 8/3 evaluates to 2).

Integer data lengths can be 1, 2, 4, or 8 bytes in length.

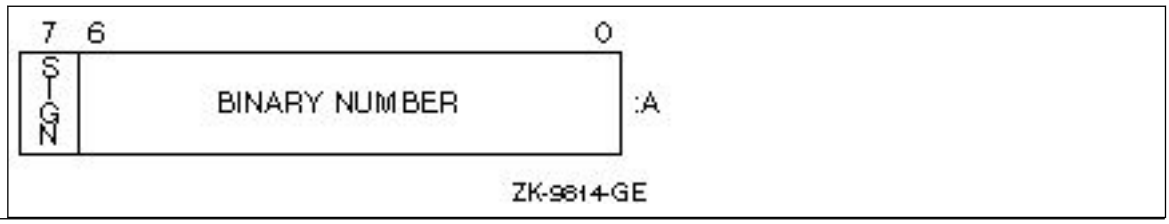
The default data size used for an INTEGER data declaration is INTEGER(4) (same as INTEGER(KIND=4)). However, you can specify a compiler option to override the default. Option `integer-size 16` can be used to specify INTEGER(2) and option `integer-size 64` can be used to specify INTEGER(8).

Integer data is signed with the sign bit being 0 (zero) for positive numbers and 1 for negative numbers.

INTEGER(KIND=1) Representation

INTEGER(1) values range from -128 to 127 and are stored in 1 byte, as shown below.

INTEGER(1) Data Representation



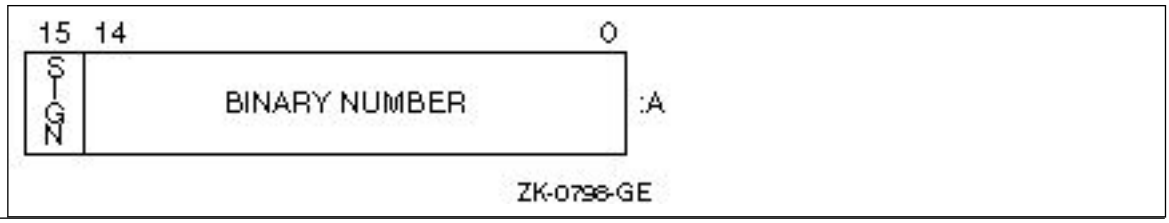
Integers are stored in a two's complement representation. For example:

```
+22 == 16 (hex)
 -7 == F9 (hex)
```

INTEGER(KIND=2) Representation

INTEGER(2) values range from -32,768 to 32,767 and are stored in 2 contiguous bytes, as shown below:

INTEGER(2) Data Representation



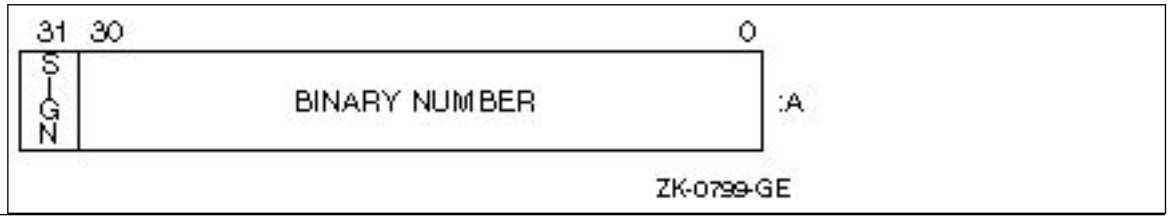
Integers are stored in a two's complement representation. For example:

```
+22 == 0016 (hex)
 -7 == FFF9 (hex)
```

INTEGER(KIND=4) Representation

INTEGER(4) values range from -2,147,483,648 to 2,147,483,647 and are stored in 4 contiguous bytes, as shown below.

INTEGER(4) Data Representation

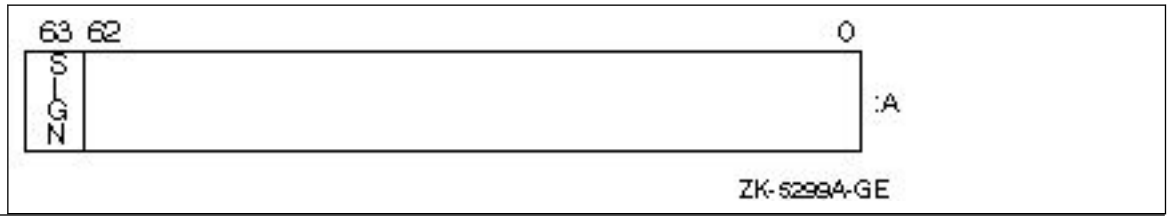


Integers are stored in a two's complement representation.

INTEGER(KIND=8) Representation

INTEGER(8) values range from -9,223,372,036,854,775,808 to 9,223,372,036,854,775,807 and are stored in 8 contiguous bytes, as shown below.

INTEGER(8) Data Representation



Integers are stored in a two's complement representation.

Logical Data Representations

Logical data can be 1, 2, 4, or 8 bytes in length.

The default data size used for a LOGICAL data declaration is LOGICAL(4) (same as LOGICAL(KIND=4)). However, you can specify a compiler option to override the default. Option `integer-size 16` can be used to specify LOGICAL(2) and option `integer-size 64` can be used to specify LOGICAL(8).

To improve performance on systems using Intel® 64 architecture, use LOGICAL(4) (or LOGICAL(8)) rather than LOGICAL(2) or LOGICAL(1). On systems using IA-32 architecture, use LOGICAL(4) rather than LOGICAL(8), LOGICAL(2), or LOGICAL(1).

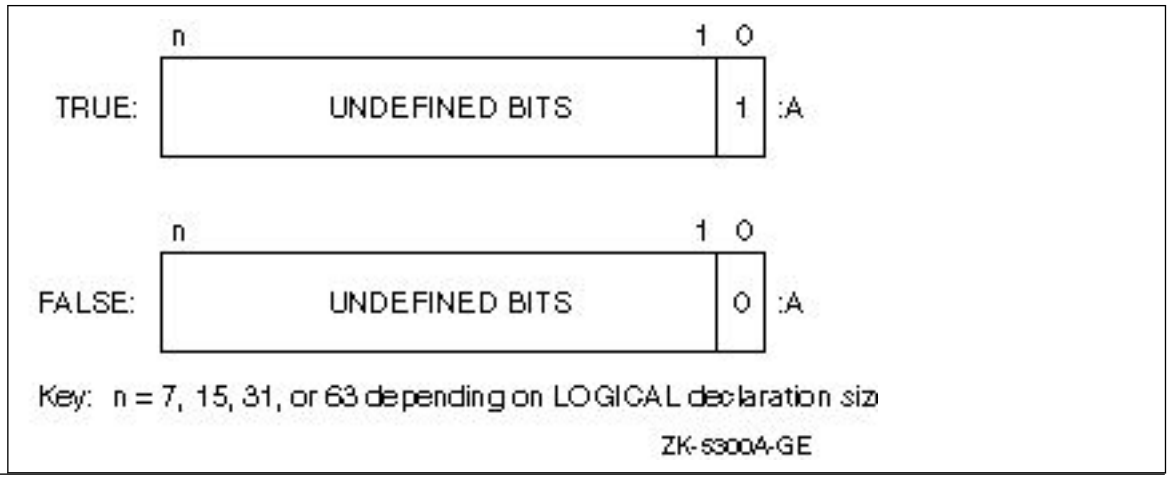
LOGICAL(KIND=1) values are stored in 1 byte. In addition to having logical values .TRUE. and .FALSE., LOGICAL(1) data can also have values in the range -128 to 127. Logical variables can also be interpreted as integer data.

In addition to LOGICAL(1), logical values can also be stored in 2 (LOGICAL(2)), 4 (LOGICAL(4)), or 8 (LOGICAL(8)) contiguous bytes, starting on an arbitrary byte boundary.

If the `fpscomp nological` compiler option is set (the default), the low-order bit determines whether the logical value is true or false. Specify `fpscomp logical` instead of `fpscomp nological` to interoperate with procedures written in C for Microsoft* Fortran PowerStation logical values, where 0 (zero) is false and non-zero values are true.

LOGICAL(1), LOGICAL(2), LOGICAL(4), and LOGICAL(8) data representations (when `fpscomp nological` is set) appear below.

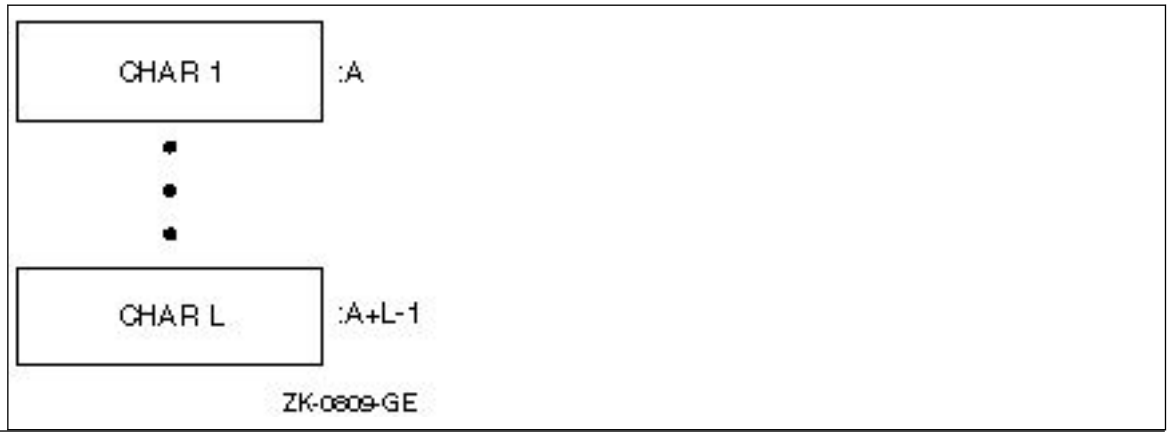
LOGICAL(1), LOGICAL(2), LOGICAL(4), and LOGICAL(8) Data Representations



Character Representation

A character string is a contiguous sequence of bytes in memory, as shown below.

CHARACTER Data Representation



A character string is specified by two attributes: the address A of the first byte of the string, and the length L of the string in bytes.

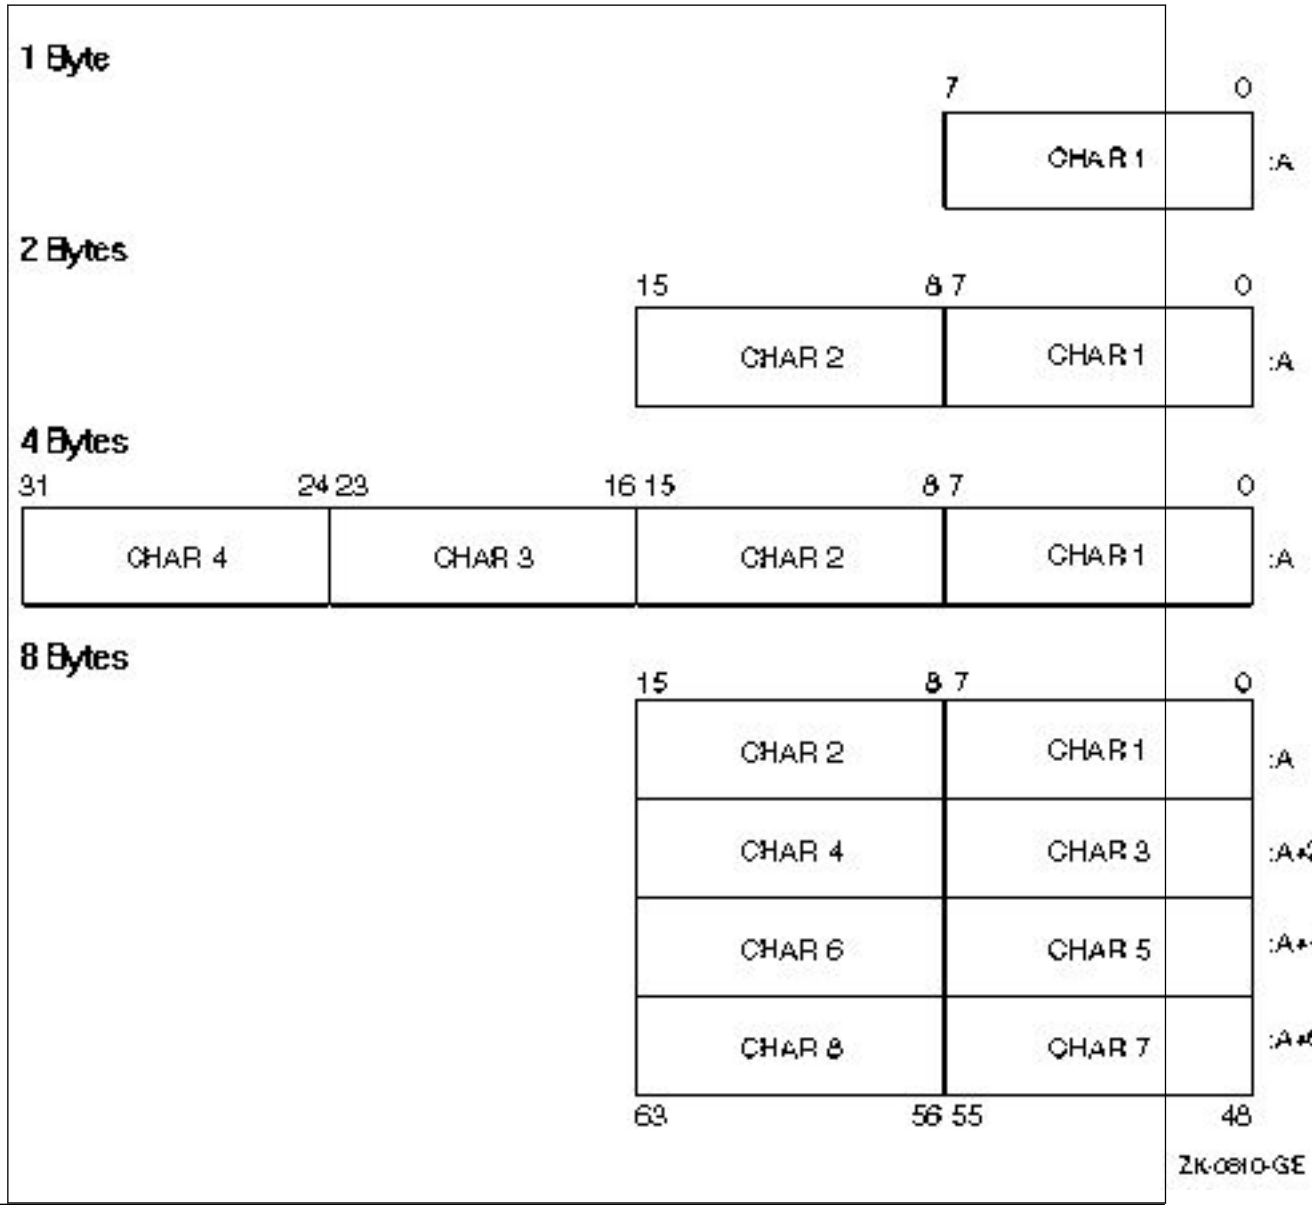
On Windows* systems, the length L of a string is in the range 1 through 2,147,483,647 (2**31-1) .

On Linux* systems, the length L of a string is in the range 1 through 2,147,483,647 (2**31-1) for systems based on IA-32 architecture and in the range 1 through 9,223,372,036,854,775,807 (2**63-1) for systems based on Intel® 64 architecture.

Hollerith Representation

Hollerith constants are stored internally, one character per byte, as shown below.

Hollerith Data Representation



Fortran I/O

In Fortran's I/O system, data is stored and transferred among files. All I/O data sources and destinations are considered files.

Devices such as the screen, keyboard, and printer are external files, as are data files stored on a device such as a disk.

Variables in memory can also act as a file on a disk and are typically used to convert ASCII representations of numbers to binary form. When variables are used in this way, they are called internal files.

For more information, see the individual topics in this section.

Logical Devices

Every file, internal or external, is associated with a logical device. You identify the logical device associated with a file by using Unit Specifier (UNIT=). The unit specifier for an internal file is the name of the character variable associated with it. The unit specifier for an external file is one of the following:

- A number you assign with the OPEN statement
- A number assigned by the Intel® Fortran run-time library with the OPEN specifier NEWUNIT=
- A number preconnected as a unit specifier to a device
- An asterisk (*)

The OPEN statement connects a unit number with an external file and allows you to explicitly specify file attributes and run-time options using OPEN statement specifiers. External unit specifiers that are preconnected to certain devices do not have to be opened. External units that you connect are disconnected when program execution terminates or when the unit is closed by a CLOSE statement.

A unit must not be connected to more than one file at a time, and a file must not be connected to more than one unit at a time. You can OPEN an already opened file but only to change some of the I/O options for the connection, not to connect an already opened file or unit to a different unit or file.

You must use a unit specifier for all I/O statements except in the following cases:

- ACCEPT, which always reads from standard input unless the FOR_ACCEPT environment variable is defined.
- INQUIRE by file, which specifies the filename rather than the unit with which the file is associated.
- PRINT, which always writes to standard output unless the FOR_PRINT environment variable is defined.
- READ statements that contain only an I/O list and format specifier, which read from standard input (UNIT=5) unless the FOR_READ environment variable is defined.
- WRITE statements that contain only an I/O list and format specifier, which write to standard output unless the FOR_WRITE environment variable is defined.
- TYPE, which always writes to standard output unless the FOR_TYPE environment variable is defined.

External Files

A unit specifier associated with an external file must be either an integer expression or an asterisk (*). The integer expression must be in the range 0 (zero) to a maximum value of 2,147,483,640. (The predefined parameters FOR_K_PRINT_UNITNO, FOR_K_TYPE_UNITNO, FOR_K_ACCEPT_UNITNO, and FOR_K_READ_UNITNO may not be in that range. For more information, see the Language Reference.)

The following example connects the external file `UNDAMP.DAT` to unit 10 and writes to it:

```
OPEN (UNIT = 10, FILE = 'UNDAMP.DAT')
WRITE (10, '(A18,\)') ' Undamped Motion:'
```

The asterisk (*) unit specifier specifies the keyboard when reading and the screen when writing. The following example uses the asterisk specifier to write to the screen:

```
WRITE (*, '(1X, A30,\)') ' Write this to the screen.'
```

Intel Fortran has four units preconnected to external files (devices), as shown in the following table.

External Unit Specifier	Environment Variable	Description
Asterisk (*)	None	Always represents the keyboard and screen (unless the appropriate environment variable is defined, such as FOR_READ).
0	FORT0	Initially represents the screen (unless FORT0 is explicitly defined)

5	FORT5	Initially represents the keyboard (unless FORT5 is explicitly defined)
6	FORT6	Initially represents the screen (unless FORT6 is explicitly defined)

The asterisk (*) specifier is the only unit specifier that cannot be reconnected to another file; attempting to close such a unit causes a compile-time error. Units 0, 5, and 6 can be connected to any file with the OPEN statement; if you close one of those units, the file is automatically reconnected to its preconnected device the next time an I/O statement attempts to use that unit.

Intel® Fortran does not support buffering to `stdin`, and does not buffer to `stdout` by default unless the `assume buffered_stdout` option is specified. All I/O to units * and 6 use line buffering by default. Therefore, C and Fortran output to `stdout` should work well as long as the C code is not performing buffering. If the C code is performing buffering, the C code will have to flush the buffers after each write. For more information on `stdout` and `stdin`, see Assigning Files to Logical Units.

You can change these preconnected files by doing one of the following:

- Using an OPEN statement to open unit 5, 6, or 0. When you explicitly OPEN a file for unit 5, 6, or 0, the OPEN statement keywords specify the file-related information to be used instead of the preconnected standard I/O file.
- Setting the appropriate environment variable (FORT*n*) to redirect I/O to an external file.

To redirect input or output from the standard preconnected files at run time, you can set the appropriate environment variable or use the appropriate shell redirection character in a pipe (such as > or <).

When you omit the file name in the OPEN statement or use an implicit OPEN, you can define the environment variable FORT*n* to specify the file name for a particular unit number *n*. An exception to this is when the `fpscomp filesfromcmd` compiler option is specified.

For example, if you want unit 6 to write to a file instead of standard output, set the environment variable FORT6 to the path and filename to be used before you run the program. If the appropriate environment variable is not defined, a default filename is used, in the form fort.*n* where *n* is the logical unit number.

The following example writes to the preconnected unit 6 (the screen), then reconnects unit 6 to an external file and writes to it, and finally reconnects unit 6 to the screen and writes to it:

```
    REAL a, b
!  Write to the screen (preconnected unit 6).
    WRITE(6, '('' This is unit 6'')')
!  Use the OPEN statement to connect unit 6
!  to an external file named 'COSINES'.
    OPEN (UNIT = 6, FILE = 'COSINES', STATUS = 'NEW')
    DO k = 1, 63, 1
         a = k/10
         b = COS (a)
!  Write to the file 'COSINES'.
          WRITE (6, 100) a, b
100        FORMAT (F3.1, F5.2)
    END DO
!  Close it.
    CLOSE (6)
!  Reconnect unit 6 to the screen, by writing to it.
    WRITE(6,' ('' Cosines completed'')')
    END
```

Internal Files

The unit specifier associated with an internal file is a scalar or array character variable:

- If the internal file is a scalar character variable, the file has only one record; its length is equal to that of the variable.
- If the internal file is an array character variable, the file has a record for each element in the array; each record's length is equal to one array element.

Follow these rules when using internal files:

- Use only formatted I/O, including I/O formatted with a format specification, namelist, and list-directed I/O. (List-directed and namelist I/O are treated as sequential formatted I/O.)
- If the character variable is an allocatable array or array part of an allocatable array, the array must be allocated before use as an internal file. If the character variable is a pointer, it must be associated with a target.
- Use only READ and WRITE statements. You cannot use file connection (OPEN, CLOSE), file positioning (REWIND, BACKSPACE), or file inquiry (INQUIRE) statements with internal files.

You can read and write internal files with FORMAT I/O statements, namelist I/O statements, or list-directed I/O statements exactly as you can external files. Before an I/O statement is executed, internal files are positioned at the beginning of the variable, before the first record.

With internal files, you can use the formatting capabilities of the I/O system to convert values between external character representations and Fortran internal memory representations. Reading from an internal file converts the ASCII representations into numeric, logical, or character representations, and writing to an internal file converts these representations into their ASCII representations.

This feature makes it possible to read a string of characters without knowing its exact format, examine the string, and interpret its contents. It also makes it possible, as in dialog boxes, for the user to enter a string and for your application to interpret it as a number.

If less than an entire record is written to an internal file, the rest of the record is filled with blanks.

In the following example, `str` and `fname` specify internal files:

```
   CHARACTER(10) str
   INTEGER n1, n2, n3
   CHARACTER(14) fname
   INTEGER   i
   str = " 1   2   3"
! List-directed READ sets n1 = 1, n2 = 2, n3 = 3.
   READ(str, *) n1, n2, n3
   i = 4
! Formatted WRITE sets fname = 'FM004.DAT'.
   WRITE (fname, 200) i
200 FORMAT ('FM', I3.3, '.DAT')
```

`assume` compiler option

Physical Devices (Windows*)

This topic only applies to Windows* operating systems.

I/O statements that do not refer to a specific file or I/O device read from standard input and write to standard output. Standard input is the keyboard, and standard output is the screen (console). To perform input and output on a physical device other than the keyboard or screen, you specify the device name as the filename to be read from or written to.

Some physical device names are determined by the host operating system; others are recognized by Intel Fortran. Extensions on most device names are ignored.

Filenames for Device I/O

Device	Description
CON	Console (standard output)
PRN	Printer
COM1	Serial port #1
COM2	Serial port #2
COM3	Serial port #3
COM4	Serial port #4
LPT1	Parallel Port #1
LPT2	Parallel Port #2
LPT3	Parallel Port #3
LPT4	Parallel Port #4
NUL	NULL device. Discards all output; contains no input
AUX	Serial port #1
LINE	Serial port #1
USER	Standard output
ERR	Standard error
CONOUT$	Standard output
CONIN$	Standard input

NOTE
If you use the LINE, USER, or ERR name with an extension, for example, LINE.TXT, Fortran will write to a file rather than to the device.

Examples of opening physical devices as units are:

```
OPEN (UNIT = 4, FILE = 'PRN')
OPEN (UNIT = 7, FILE = 'LPT2', ERR = 100)
```

Types of I/O Statements

The table below lists the Intel Fortran I/O statements:

Category and statement name	Description
File connection	
OPEN	Connects a unit number with an external file and specifies file connection characteristics.
CLOSE	Disconnects a unit number from an external file.
File inquiry	

Category and statement name	Description
DEFINE FILE	Specifies file characteristics for a direct access relative file and connects the unit number to the file, similar to an OPEN statement. Provided for compatibility with compilers older than FORTRAN-77.
INQUIRE	Returns information about a named file, a connection to a unit, or the length of an output item list.
Record position	
BACKSPACE	Moves the record position to the beginning of the previous record (sequential access only).
DELETE	Marks the record at the current record position in a relative file as deleted (direct access only).
ENDFILE	Writes an end-of-file marker after the current record (sequential access only).
FIND	Changes the record position in a direct access file. Provided for compatibility with compilers older than FORTRAN-77.
REWIND	Sets the record position to the beginning of the file (sequential access only).
Record input	
READ	Transfers data from an external file record or an internal file to internal storage.
ACCEPT	Reads input from stdin. Unlike READ, ACCEPT only provides formatted sequential input and does not specify a unit number.
Record output	
WRITE	Transfers data from internal storage to an external file record or to an internal file.
REWRITE	Transfers data from internal storage to an external file record at the current record position (direct access relative files only).
TYPE	Writes record output to stdout.
PRINT	Transfers data from internal storage to stdout. Unlike WRITE, PRINT only provides formatted sequential output and does not specify a unit number.
FLUSH	Flushes the contents of an external unit's buffer to its associated file.

In addition to the READ, WRITE, REWRITE, TYPE, and PRINT statements, other I/O record-related statements are limited to a specific file organization. For instance:

- The DELETE statement only applies to relative files. (Detecting deleted records is only available if the `vms` option was specified when the program was compiled.)
- The BACKSPACE statement only applies to sequential files open for sequential access.
- The REWIND statement only applies to sequential files open for sequential access and to direct access files.
- The ENDFILE statement only applies to certain types of sequential files open for sequential access and to direct access files.

The file-related statements (OPEN, INQUIRE, and CLOSE) apply to any relative or sequential file.

Forms of I/O Statements

Each type of record I/O statement can be coded in a variety of forms. The form you select depends on the nature of your data and how you want it treated. When opening a file, specify the form using the FORM specifier.

The following are the forms of I/O statements:

- *Formatted I/O statements* contain explicit format specifiers that are used to control the translation of data from internal (binary) form within a program to external (readable character) form in the records, or vice versa.
- *List-directed* and *namelist I/O statements* are similar to formatted statements in function. However, they use different mechanisms to control the translation of data: formatted I/O statements use explicit format specifiers, and list-directed and namelist I/O statements use data types.
- *Unformatted I/O statements* do not contain format specifiers and therefore do not translate the data being transferred (important when writing data that will be read later).

Formatted, list-directed, and namelist I/O forms require translation of data from internal (binary) form within a program to external (readable character) form in the records. Consider using unformatted I/O for the following reasons:

- Unformatted data avoids the translation process, so I/O tends to be faster.
- Unformatted data avoids the loss of precision in floating-point numbers when the output data will subsequently be used as input data.
- Unformatted data conserves file storage space (stored in binary form).

To write data to a file using formatted, list-directed, or namelist I/O statements, specify FORM= 'FORMATTED' when opening the file. To write data to a file using unformatted I/O statements, specify FORM= 'UNFORMATTED' when opening the file.

Data written using formatted, list-directed, or namelist I/O statements is referred to as *formatted data*. Data written using unformatted I/O statements is referred to as *unformatted data*.

When reading data from a file, you should use the same I/O statement form that was used to write the data to the file. For instance, if data was written to a file with a formatted I/O statement, you should read data from that file with a formatted I/O statement.

Although I/O statement form is usually the same for reading and writing data in a file, a program can read a file containing unformatted data (using unformatted input) and write it to a separate file containing formatted data (using formatted output). Similarly, a program can read a file containing formatted data and write it to a different file containing unformatted data.

You can access records in any sequential or relative file using sequential access. For relative files and certain (fixed-length) sequential files, you can also access records using direct access.

The table below shows categories for the main record I/O statements that can be used in Intel® Fortran programs.

File Type, Access, and I/O Form	Available Statements
External file, sequential access	
Formatted	READ, WRITE, PRINT, ACCEPT, TYPE, REWRITE
List-directed	READ, WRITE, PRINT, ACCEPT, TYPE
Namelist	READ, WRITE, PRINT, ACCEPT, TYPE
Unformatted	READ, WRITE, REWRITE
External file, direct access	
Formatted	READ, WRITE, REWRITE
Unformatted	READ, WRITE, REWRITE
External file, stream access	
Formatted	READ, WRITE
List-directed	READ, WRITE
Namelist	READ, WRITE

File Type, Access, and I/O Form	Available Statements
Unformatted	READ, WRITE
Internal file	
Formatted	READ, WRITE
List-directed	READ, WRITE
Unformatted	None

NOTE
You can use the REWRITE statement only for relative files, using direct access.

Assigning Files to Logical Units

Most I/O operations involve a disk file, keyboard, or screen display. Other devices can also be used:

- Sockets can be read from or written to if a USEROPEN routine (usually written in C) is used to open the socket.
- Pipes opened for read and write access block (wait until data is available) if you issue a READ to an empty pipe.
- Pipes opened for read-only access return EOF if you issue a READ to an empty pipe.

You can access the terminal screen or keyboard by using preconnected files listed in Logical Devices.

You can choose to assign files to logical units by using one of the following methods:

- Using default values, such as a preconnected unit
- Supplying a file name (and possibly a directory) in an OPEN statement
- Using environment variables

Using Default Values

In the following example, the PRINT statement is associated with a preconnected unit (stdout) by default.

```
PRINT *,100
```

The READ statement associates the logical unit 7 with the file `fort.7` (because the FILE specifier was omitted) by default:

```
OPEN (UNIT=7,STATUS='NEW')
READ (7,100)
```

Supplying a File Name in an OPEN Statement

The FILE specifier in an OPEN statement typically specifies only a file name (such as `filnam`) or contains both a directory and file name (such as `/usr/proj/filnam`).

For example:

```
OPEN (UNIT=7, FILE='FILNAM.DAT', STATUS='OLD')
```

The DEFAULTFILE specifier in an OPEN statement typically specifies a pathname that contains only a directory (such as `/usr/proj/`) or both a directory and file name (such as `/usr/proj/testdata`).

Implied OPEN

Performing an implied OPEN means that the FILE and DEFAULTFILE specifier values are not specified and an environment variable is used, if present. Thus, if you used an implied OPEN, or if the FILE specifier in an OPEN statement did not specify a file name, you can use an environment variable to specify a file name or a pathname that contains both a directory and file name.

Using Environment Variables

You can use shell commands to set the appropriate environment variable to a value that indicates a directory (if needed) and a file name to associate a unit with an external file.

Intel Fortran recognizes environment variables for each logical I/O unit number in the form of FORT`n`, where `n` is the logical I/O unit number. If a file name is not specified in the OPEN statement and the corresponding FORT`n` environment variable is not set for that unit number, Intel Fortran generates a file name in the form fort.`n`, where `n` is the logical unit number.

Implied Intel Fortran Logical Unit Numbers

The ACCEPT, PRINT, and TYPE statements, and the use of an asterisk (*) in place of a unit number in READ and WRITE statements, do not include an explicit logical unit number.

Each of these Fortran statements uses an implicit internal logical unit number and environment variable. Each environment variable is in turn associated by default with one of the Fortran file names that are associated with standard I/O files. The table below shows these relationships:

Intel Fortran statement	Environment variable	Standard I/O file name
READ (*,f) iolist	FOR_READ	stdin
READ f,iolist	FOR_READ	stdin
ACCEPT f,iolist	FOR_ACCEPT	stdin
WRITE (*,f) iolist	FOR_PRINT	stdout
PRINT f,iolist	FOR_PRINT	stdout
TYPE f,iolist	FOR_TYPE	stdout
WRITE(0,f) iolist	FORT0	stderr
READ(5,f) iolist	FORT5	stdin
WRITE(6,f) iolist	FORT6	stdout

You can change the file associated with these Intel Fortran environment variables, as you would any other environment variable, by means of the environment variable assignment command. For example:

```
setenv FOR_READ /usr/users/smith/test.dat
```

After executing the preceding command, the environment variable for the READ statement using an asterisk refers to file `test.dat` in the specified directory.

NOTE
The association between the logical unit number and the physical file can occur at run-time. Instead of changing the logical unit numbers specified in the source program, you can change this association at run time to match the needs of the program and the available resources. For example, before running the program, a script file can set the appropriate environment variable or allow the terminal user to type a directory path, file name, or both.

File Organization

File organization refers to the way records are physically arranged on a storage device. This topic describes the two main types of file organization.

Related topics describe the following:

- *Record type* refers to whether records in a file are all the same length, are of varying length, or use other conventions to define where one record ends and another begins. For more information on record types, see Record Types.
- *Record access* refers to the method used to read records from or write records to a file, regardless of its organization. The way a file is organized does not necessarily imply the way in which the records within that file will be accessed. For more information on record access, see File Access and File Structure and Record Access.

Types of File Organization

Fortran supports two types of file organizations:

- Sequential
- Relative

The organization of a file is specified by means of the ORGANIZATION keyword in the OPEN statement.

The default file organization is always ORGANIZATION= 'SEQUENTIAL' for an OPEN statement.

You can store sequential files on magnetic tape or disk devices, and can use other peripheral devices, such as terminals, pipes, and line printers as sequential files.

You must store relative files on a disk device.

Sequential File Organization

A sequentially organized file consists of records arranged in the sequence in which they are written to the file (the first record written is the first record in the file, the second record written is the second record in the file, and so on). As a result, records can be added only at the end of the file. Attempting to add records at some place other than the end of the file will result in the file begin truncated at the end of the record just written.

Sequential files are usually read sequentially, starting with the first record in the file. Sequential files with a fixed-length record type that are stored on disk can also be accessed by relative record number (direct access).

Relative File Organization

Within a relative file are numbered positions, called *cells*. These cells are of fixed equal length and are consecutively numbered from 1 to *n*, where 1 is the first cell, and *n* is the last available cell in the file. Each cell either contains a single record or is empty. Records in a relative file are accessed according to cell number. A cell number is a record's relative record number; its location relative to the beginning of the file. By specifying relative record numbers, you can directly retrieve, add, or delete records regardless of their locations. You can only detect deleted records if you specify option `vms` when the program is compiled.

When creating a relative file, use the RECL value to determine the size of the fixed-length cells. Within the cells, you can store records of varying length, as long as their size does not exceed the cell size.

Internal Files and Scratch Files

Intel Fortran also supports internal files and scratch files.

Internal Files

When you use sequential access, you can use an internal file to reference character data in a buffer. The transfer occurs between internal storage spaces (unlike external files), such as between user variables and a character array.

An internal file consists of any of the following:

- Character variable
- Character-array element
- Character array
- Character substring
- Character array section without a vector subscript

Instead of specifying a unit number for the READ or WRITE statement, use an internal file specifier in the form of a character scalar memory reference or a character-array name reference.

An internal file is a designated internal storage space (variable buffer) of characters that is treated as a sequential file of fixed-length records. To perform internal I/O, use formatted and list-directed sequential READ and WRITE statements. You cannot use file-related statements such as OPEN and INQUIRE on an internal file (no unit number is used).

If an internal file is made up of a single character variable, array element, or substring, that file comprises a single record whose length is the same as the length of the character variable, array element, or substring it contains. If an internal file is made up of a character array, that file comprises a sequence of records, with each record consisting of a single array element. The sequence of records in an internal file is determined by the order of subscript progression.

A record in an internal file can be read only if the character variable, array element, or substring comprising the record has been defined (a value has been assigned to the record).

Prior to each READ and WRITE statement, an internal file is always positioned at the beginning of the first record.

Scratch Files

Scratch files are created by specifying STATUS= 'SCRATCH' in an OPEN statement. By default, these temporary files are created by an OPEN statement and are deleted when closed.

File Access and File Structure

Fortran supports three methods of file access:

- Sequential
- Direct
- Stream

Fortran supports three kinds of file structure:

- Formatted
- Unformatted
- Binary

Sequential-access and direct-access files can have any of the three file structures. Stream-access files can have a file structure of formatted or unformatted.

Choosing a File Access and File Structure

Each kind of file has advantages and the best choice depends on the application you are developing:

- Formatted Files

You create a formatted file by opening it with the FORM='FORMATTED' option, or by omitting the FORM parameter when creating a sequential file. The records of a formatted file are stored as ASCII characters. Numbers that would otherwise be stored in binary form are converted to ASCII format. Each record ends with the ASCII carriage return (CR) and/or line feed (LF) characters.

If you need to view a data file's contents, use a formatted file. You can load a formatted file into a text editor and read its contents directly. The numbers will look like numbers and the strings will look like character strings (an unformatted or binary file looks like a set of hexadecimal characters).

- Unformatted Files

  You create an unformatted file by opening it with the FORM='UNFORMATTED' option, or by omitting the FORM parameter when creating a direct-access file. An unformatted file is a series of records composed of physical blocks. Each record contains a sequence of values stored in a representation that is close to that used in program memory. Little conversion is required during input/output.

  The lack of formatting makes these files quicker to access and more compact than files that store the same information in a formatted form. However, if the files contain numbers, you will not be able to read them with a text editor.
- Binary Files

  You create a binary file by specifying FORM='BINARY'. Binary files are similar to unformatted files, except binary files have no internal record format associated with them.
- Sequential-Access Files

  Data in sequential files must be accessed in order, one record after the other (unless you change your position in the file with the REWIND or BACKSPACE statements). Some methods of I/O are possible only with sequential files, including nonadvancing I/O, list-directed I/O, and namelist I/O. Internal files also must be sequential files. You must use sequential access for files associated with sequential devices.

  A sequential device is a physical storage device that does not allow explicit motion (other than reading or writing). The keyboard, screen, and printer are all sequential devices.
- Direct-Access Files

  Data in direct-access files can be read or written to in any order. Records are numbered sequentially, starting with record number 1. All records have the length specified by the RECL option in the OPEN statement. Data in direct-access files is accessed by specifying the record you want within the file. If you need random access I/O, use direct-access files. A common example of a random-access application is a database.
- Stream-Access Files

  Stream-access I/O is a method of accessing a file without reference to a record structure. With stream access, a file is seen as a continuous sequence of bytes and is addressed by a positive integer starting from 1.

  To enable stream access, specify ACCESS='STREAM' in the OPEN statement for the file. You can use the STREAM= specifier in the INQUIRE statement to determine if STREAM is listed in the set of possible access methods for the file. A value of YES, NO, or UNKNOWN is returned.

  A file enabled for stream access is positioned by file storage units (normally bytes) starting at position 1. To determine the current position, use the POS= specifier in an INQUIRE statement for the unit. You can indicate a required position in a read or write statement with a POS= specifier.

  Stream access can be either formatted or unformatted.

  When connected for formatted stream access, an external file has the following characteristics:

  - The first file storage unit in the file is at position 1. The relationship between positions of successive file storage units is processor dependent; not all positive integers need to correspond to valid positions.
  - Some file storage units may contain record markers; this imposes a record structure on the file in addition to its stream structure. If there is no record marker at the end of the file, the final record is incomplete. Writing an empty record with no record marker has no effect.

When connected for unformatted stream access, an external file has the following characteristics:

- The first file storage unit in the file is at position 1. The position of each subsequent file storage unit is one greater than that of the preceding file storage unit.
- If it is possible to position the file, the file storage units do not need to be read or written in order of their position. For example, you may be able to write the file storage unit at position 2, even though the file storage unit at position 1 has not been written.
- Any file storage unit may be read from the file while it is connected to a unit, provided that the file storage unit has been written since the file was created, and a READ statement for this connection is allowed.
- You cannot use BACKSPACE in an unformatted stream.

File Records

Files may be composed of records. Each record is one entry in the file. A record can be a line from a terminal or a logical record on a magnetic tape or disk file. All records within one file are of the same type.

In Fortran, the number of bytes transferred to a record must be less than or equal to the record length. One record is transferred for each unformatted READ or WRITE statement. A formatted READ or WRITE statement can transfer more than one record using the slash (`/`) edit descriptor.

For binary files, a single READ or WRITE statement reads or writes as many records as needed to accommodate the number of bytes being transferred. On output, incomplete formatted records are padded with spaces. Incomplete unformatted and binary records are padded with undefined bytes (zeros).

Record Types

An I/O record is a collection of data items, called *fields*, which are logically related and are processed as a unit. The record type refers to the convention for storing fields in records.

The record type of the data within a file is not maintained as an attribute of the file. The results of using a record type other than the one used to create the file are indeterminate.

A number of record types are available, as shown in the following table. The table also lists the record overhead. This refers to bytes associated with each record that are used internally by the file system and are not available when a record is read or written. Knowing the record overhead helps when estimating the storage requirements for an application. Although the overhead bytes exist on the storage media, do not include them when specifying the record length with the RECL specifier in an OPEN statement.

Record Type	Available File Organizations and Portability Considerations	Record Overhead
Fixed-length	Relative or sequential file organizations.	None for sequential or for relative if the `vms` option is omitted or option `novms` is specified. One byte for relative if the `vms` option is specified.
Variable-length	Sequential file organization only. The variable-length record type is generally the most portable record type across multi-vendor platforms.	Eight bytes per record.
Segmented	Sequential file organization only and only for unformatted sequential access. The segmented record type is unique to Intel Fortran and should not be used for portability with programs written in languages other than Fortran or for places where Intel Fortran is not used. However, because the	Four bytes per record. One additional padding byte (space) is added if the specified record size is an odd number.

Record Type	Available File Organizations and Portability Considerations	Record Overhead
	segmented record type is unique to Intel Fortran products, formatted data in segmented files can be ported across Intel Fortran platforms.	
Stream (uses no record terminator)	Sequential file organization only.	None required.
Stream_CR (uses CR as record terminator)	Sequential file organization only.	One byte per record.
Stream_LF (uses LF as record terminator)	Sequential file organization only.	One byte per record.
Stream_CRLF (uses CR and LF as record terminator)	Sequential file organization only.	Two bytes per record.

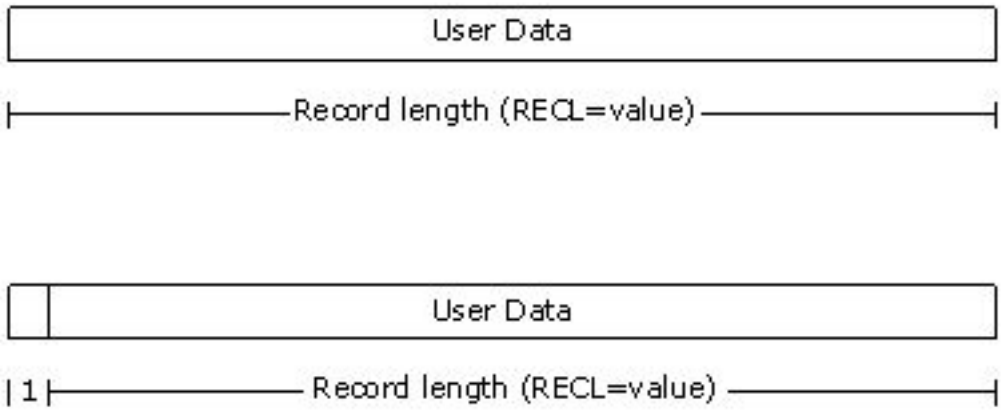
Fixed-Length Records

When you specify fixed-length records, you are specifying that all records in the file contain the same number of bytes. When you open a file that is to contain fixed-length records, you must specify the record size using the RECL keyword. A sequentially organized opened file for direct access must contain fixed-length records, to allow the record position in the file to be computed correctly.

For relative files, the layout and overhead of fixed-length records depends upon whether the program accessing the file was compiled using the `vms` option:

- For relative files where the `vms` option is omitted (the default), each record has no control information.
- For relative files where the `vms` option is specified, each record has one byte of control information at the beginning of the record.

The following figures show the record layout of fixed-length records. The first is for all sequential and relative files where the `vms` option is omitted. The second is for relative files where the `vms` option is specified.



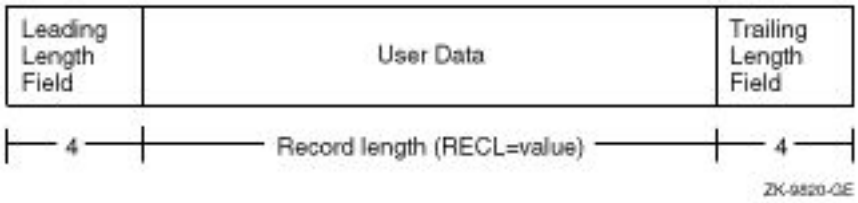
Variable-Length Records

Variable-length records can contain any number of bytes up to a specified maximum record length, and apply only to sequential files.

Variable-length records are prefixed and suffixed by 4 bytes of control information containing length fields. The trailing length field allows a BACKSPACE request to skip back over records efficiently. The 4-byte integer value stored in each length field indicates the number of data bytes (excluding overhead bytes) in that particular variable-length record.

The character count field of a variable-length record is available when you read the record by issuing a READ statement with a Q format descriptor. You can then use the count field information to determine how many bytes should be in an I/O list.

The following shows the record layout of variable-length records that are less than 2 gigabytes:



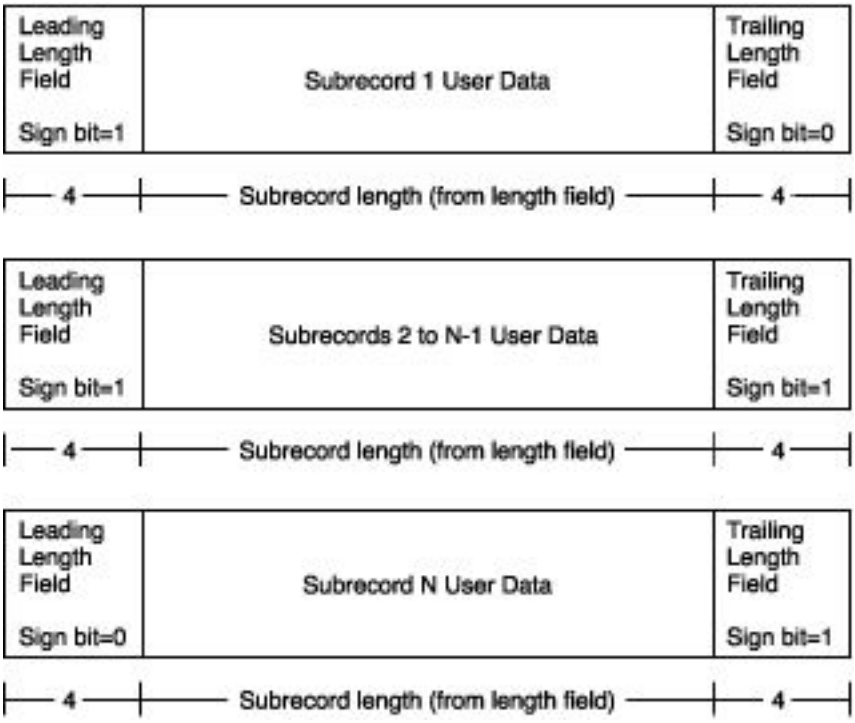
For a record length greater than 2,147,483,639 bytes, the record is divided into *subrecords*. The subrecord can be of any length from 1 to 2,147,483,639, inclusive.

The sign bit of the leading length field indicates whether the record is continued or not. The sign bit of the trailing length field indicates the presence of a preceding subrecord. The position of the sign bit is determined by the endian format of the file.

The following rules describe sign bit values:

- A subrecord that is continued has a leading length field with a sign bit value of 1.
- The last subrecord that makes up a record has a leading length field with a sign bit value of 0.
- A subrecord that has a preceding subrecord has a trailing length field with a sign bit value of 1.
- The first subrecord that makes up a record has a trailing length field with a sign bit value of 0.
- If the value of the sign bit is 1, the length of the record is stored in twos-complement notation.

The following shows the record layout of variable-length records that are greater than 2 gigabytes:



Files written with variable-length records by Intel Fortran programs usually cannot be accessed as text files. Instead, use the Stream_LF record format for text files with records of varying length.

Segmented Records

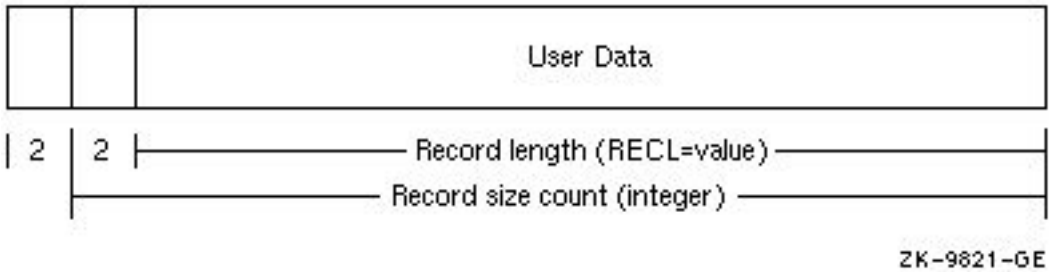
A segmented record is a single logical record consisting of one or more variable-length, unformatted records in a sequentially organized disk file. Unformatted data written to sequentially organized files using sequential access is stored as segmented records by default.

Segmented records are useful when you want to write exceptionally long records but cannot or do not wish to define one long variable-length record, perhaps because virtual memory limitations can prevent program execution. By using smaller, segmented records, you reduce the chance of problems caused by virtual memory limitations on systems on which the program may execute.

For disk files, the segmented record is a single logical record that consists of one or more segments. Each segment is a physical record. A segmented (logical) record can exceed the absolute maximum record length (2.14 billion bytes), but each segment (physical record) individually cannot exceed the maximum record length.

To access an unformatted sequential file that contains segmented records, specify FORM='UNFORMATTED' and RECORDTYPE='SEGMENTED' when you open the file.

The following shows that the layout of segmented records consists of 4 bytes of control information followed by the user data:



The control information consists of a 2-byte integer record length count (includes the 2 bytes used by the segment identifier), followed by a 2-byte integer segment identifier that identifies this segment as one of the following:

Identifier Value	Segment Identified
0	One of the segments between the first and last segments
1	First segment
2	Last segment
3	Only segment

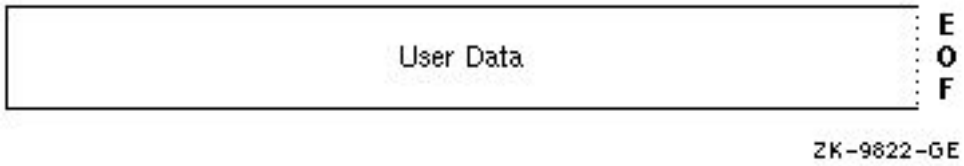
If the specified record length is an odd number, the user data will be padded with a single blank (one byte), but this extra byte is not added to the 2-byte integer record size count.

Avoid the segmented record type when the application requires that the same file be used for programs written in languages other than Intel Fortran and for non-Intel platforms.

Stream File Data

A stream file is not grouped into records and contains no control information. Stream files are used with CARRIAGECONTROL='NONE' and contain character or binary data that is read or written only to the extent of the variables specified on the input or output statement.

The following shows the layout of a stream file:



Stream_CR, Stream_LF and Stream_CRLF Records

Stream_CR, Stream_LF, and Stream_CRLF records are variable-length records whose length is indicated by explicit record terminators embedded in the data, not by a count. These terminators are automatically added when you write records to a stream-type file and are removed when you read records.

Each variety uses either a different 1-byte or 2-byte record terminator:

- Stream_CR files must not contain embedded carriage-return characters because Stream_CR files use only a carriage-return as the terminator.
- Stream_LF files must not contain embedded line-feed (new line) characters because Stream_LF files use only a line-feed (new line) as the terminator. This is the usual operating system text file record type on Linux* OS and macOS* systems.
- Stream_CRLF files must not contain embedded carriage returns or line-feed (new line) characters because Stream_CRLF files use a carriage return/line-feed (new line) pair as the terminator. This is the usual operating system text file record type on Windows* systems.

Guidelines for Choosing a Record Type

Before you choose a record type, consider whether your application will use formatted or unformatted data. If you are using formatted data, you can choose any record type except segmented. If you are using unformatted data, avoid the Stream, Stream_CR, Stream_LF and Stream_CRLF record types.

The segmented record type can only be used for unformatted sequential access with sequential files. You should not use segmented records for files that are read by programs written in languages other than Intel Fortran.

The Stream, Stream_CR, Stream_LF, Stream_CRLF and segmented record types can be used only with sequential files.

The default record type (RECORDTYPE) depends on the values for the ACCESS and FORM specifiers for the OPEN statement. (The RECORDTYPE= specifier is ignored for stream access.)

The record type of the file is not maintained as an attribute of the file. The results of using a record type other than the one used to create the file are indeterminate.

An I/O record is a collection of fields (data items) that are logically related and are usually processed as a unit.

Unless you specify nonadvancing I/O (ADVANCE specifier), each Intel Fortran I/O statement transfers at least one record.

Specifying the Line Terminator for Formatted Files

Use the FOR_FMT_TERMINATOR environment variable to specify the line terminator value used for Fortran formatted files with no explicit RECORDTYPE= specifier.

The FOR_FMT_TERMINATOR environment variable is processed once at the beginning of program execution. Whatever it specifies for specific units continues for the rest of the execution.

You can specify the numbers of the units to have a specific record terminator. The READ/WRITE statements that use these unit numbers will now use the specified record terminators. Other READ/WRITE statements will work in the usual way.

A RECORDTYPE=specifier on an OPEN statement overrides the value set by FOR_FMT_TERMINATOR. The FOR_FMT_TERMINATOR value is ignored for ACCESS='STREAM' files.

General Syntax for FOR_FMT_TERMINATOR

The syntax for this environment variable is as follows:

```
FOR_FMT_TERMINATOR=MODE[:ULIST][;MODE[:ULIST]]
```

where:

```
MODE=CR | LF | CRLF
ULIST = U | ULIST,U
U = decimal | decimal - decimal
```

- MODE specifies the record terminator to be used. The keyword `CR` means to terminate records with a carriage return. The keyword LF means to terminate records with a line feed; this is the default on Linux* OS and macOS* systems. The keyword CRLF means to terminate records with a carriage return/line feed pair; this is the default on Windows systems.
- Each list member "U" is a simple unit number or a number of units as a range. The number of list members is limited to 64.
- "decimal" is a non-negative decimal number less than 232.

No spaces are allowed inside the FOR_FMT_TERMINATOR value.

On Linux* systems, the following shows the command line for the variable setting in a bash-style shell:

```
Sh: export FOR_FMT_TERMINATOR=MODE:ULIST
```

NOTE
The environment variable value should be enclosed in quotes if the semicolon is present.

Example:

The following specifies that all input/output operations on unit numbers 10, 11, and 12 have records terminated with a carriage return/line feed pair:

```
FOR_FMT_TERMINATOR=CRLF:10-12
```

Record Length

Use the RECL specifier to specify the record length.

The units used for specifying record length depend on the form of the data:

- Formatted files (FORM= 'FORMATTED'): Specify the record length in bytes.
- Unformatted files (FORM= 'UNFORMATTED'): Specify the record length in 4-byte units, unless you specify the `assume byterecl` compiler option to request 1-byte units.

For all but variable-length sequential records on 64-bit addressable systems, the maximum record length is 2.147 billion bytes (2,147,483,647 minus the bytes for record overhead). For variable-length sequential records on 64-bit addressable systems, the theoretical maximum record length is about 17,000 gigabytes. When considering very large record sizes, also consider limiting factors such as system virtual memory.

NOTE
The RECL specifier is ignored for stream access.

Record Access

Record access refers to how records will be read from or written to a file, regardless of the file's organization. Record access is specified each time you open a file; it can be different each time. The type of record access permitted is determined by the combination of file organization and record type.

For example, you can fo the following:

- Add records to a sequential file with ORGANIZATION= 'SEQUENTIAL' and POSITION= 'APPEND' (or use ACCESS= 'APPEND').
- Add records sequentially by using multiple WRITE statements, close the file, and then open it again with ORGANIZATION= 'SEQUENTIAL' and ACCESS= 'SEQUENTIAL' (or ACCESS= 'DIRECT' if the sequential file has fixed-length records).

Sequential Access

Sequential access transfers records sequentially to or from files or I/O devices such as terminals. You can use sequential I/O with any type of supported file organization and record type.

If you select sequential access mode for files with sequential or relative organization, records are written to or read from the file starting at the beginning of the file and continuing through it, one record after another. A particular record can be retrieved only after all of the records preceding it have been read; new records can be written only at the end of the file.

Direct Access

Direct access transfers records selected by record number to and from either sequential files stored on disk with a fixed-length record type or relative organization files.

If you select direct access mode, you can determine the order in which records are read or written. Each READ or WRITE statement must include the relative record number, indicating the record to be read or written.

You can directly access a sequential disk file only if it contains fixed-length records. Because direct access uses cell numbers to find records, you can enter successive READ or WRITE statements requesting records that either precede or follow previously requested records. For example, the first of the following statements reads record 24; the second reads record 10:

```
READ (12,REC=24) I
READ (12,REC=10) J
```

Stream Access

Stream access transfers bytes from records sequentially until a record terminator is found or a specified number of bytes have been read or written. Formatted stream records are terminated with a new line character; unformatted stream data contains no record terminators. Bytes can be read from or written to a file by byte position, where the first byte of the file is position 1. For example:

```
OPEN (UNIT=12, ACCESS='STREAM')
READ (12) I, J, K           ! start at the first byte of the file
READ (12, POS=200) X, Y     ! then read staring at byte 200
READ (12) A, B              ! then read starting where the previous READ stopped
```

The POS= specifier on INQUIRE can be used to determine the current byte position in the file.

NOTE
The RECORDTYPE= specifier is ignored for stream access.

Limitations of Record Access by File Organization and Record Type

You can use sequential and direct access modes on sequential and relative files. However, direct access to a sequential organization file can only be done if the file resides on disk and contains fixed-length records.

The table below summarizes the types of access permitted for the various combinations of file organizations and record types.

Record Type	Sequential Access?	Direct Access?
Sequential file organization		
Fixed	Yes	Yes
Variable	Yes	No
Segmented	Yes	No
Stream	Yes	No
Stream_CR	Yes	No
Stream_LF	Yes	No
Stream_CRLF	Yes	No
Relative file organization		
Fixed	Yes	Yes

NOTE
Direct access and relative files require that the file resides on a disk device.

Record Transfer

I/O statements transfer all data as records. The amount of data that a record can contain depends on the following circumstances:

- With formatted I/O (except for fixed-length records), the number of items in the I/O statement and its associated format specifier jointly determine the amount of data to be transferred.
- With namelist and list-directed output, the items listed in the NAMELIST statement or I/O statement list (in conjunction with the NAMELIST or list-directed formatting rules) determine the amount of data to be transferred.
- With unformatted I/O (except for fixed-length records), the I/O statement alone specifies the amount of data to be transferred.
- When you specify fixed-length records (RECORDTYPE= 'FIXED'), all records are the same size. If the size of an I/O record being written is less than the record length (RECL), extra bytes are added (padding).

Typically, the data transferred by an I/O statement is read from or written to a single record. It is possible, however, for a single I/O statement to transfer data from or to more than one record, depending on the form of I/O used.

Input Record Transfer

When using advancing I/O, if an input statement specifies fewer data fields (less data) than the record contains, the remaining fields are ignored.

If an input statement specifies more data fields than the record contains, one of the following occurs:

- For formatted input using advancing I/O, if the file was opened with PAD='YES', additional fields are read as spaces. If the file is opened with PAD='NO', an error occurs (the input statement should not specify more data fields than the record contains).
- For formatted input using nonadvancing I/O (ADVANCE='NO'), an end-of-record (EOR) condition is returned. If the file was opened with PAD='YES', additional fields are read as spaces.
- For list-directed input, another record is read.
- For NAMELIST input, another record is read.
- For unformatted input, an error occurs.

Output Record Transfer

If an output statement specifies fewer data fields than the record contains (less data than required to fill a record), the following occurs:

- With fixed-length records (RECORDTYPE= 'FIXED'), all records are the same size. If the size of an I/O record being written is less than the record length (RECL), extra bytes are added (padding) in the form of spaces (for a formatted record) or zeros (for an unformatted record).
- With other record types, the fields present are written and those omitted are not written (might result in a short record).

If the output statement specifies more data than the record can contain, an error occurs, as follows:

- With formatted or unformatted output using fixed-length records, if the items in the output statement and its associated format specifier result in a number of bytes that exceeds the maximum record length (RECL), an error occurs.
- With formatted or unformatted output not using fixed-length records, if the items in the output statement and its associated format specifier result in a number of bytes that exceeds the maximum record length (RECL), the Intel Fortran RTL attempts to increase the RECL value and write the longer record. To obtain the RECL value, use an INQUIRE statement.
- For list-directed output and namelist output, if the data specified exceeds the maximum record length (RECL), another record is written.

Specifying Default Pathnames and File Names

Intel® Fortran provides a number of ways of specifying all or part of a file specification (directory and file name). The following list uses the Linux* pathname `/usr/proj/testdata` as an example:

- The FILE specifier in an OPEN statement typically specifies only a file name (such as testdata) or contains both a directory and file name (such as `/usr/proj/testdata`).
- The DEFAULTFILE specifier in an OPEN statement typically specifies a pathname that contains only a directory (such as `/usr/proj/`) or both a directory and file name (such as `/usr/proj/testdata`).
- If you used an implied OPEN (described in Assigning Files to Logical Units) or if the FILE specifier in an OPEN statement did not specify a file name, you can use an environment variable to specify a file name or a pathname that contains both a directory and file name.

Examples of Applying Default Pathnames and File Names

For example, for an implied OPEN of unit number 3, Intel Fortran will check the environment variable FORT3. If the environment variable FORT3 is set, its value is used. If it is not set, the system supplies the file name `fort.3`.

In the following table, assume the current directory is `/usr/smith` and the I/O uses unit 1, as in the statement READ (1,100).

OPEN FILE value	OPEN DEFAULTFILE value	FORT1 environment variable value	Resulting pathname
not specified	not specified	not specified	/usr/smith/fort.1
not specified	not specified	test.dat	/usr/smith/test.dat
not specified	not checked	/usr/tmp/t.dat	/usr/tmp/t.dat
not specified	/tmp	not specified	/tmp/fort.1
not specified	/tmp	testdata	/tmp/testdata
not specified	/usr	lib/testdata	/usr/lib/testdata
file.dat	/usr/group	not checked	/usr/group/file.dat
/tmp/file.dat	not checked	not checked	/tmp/file.dat
file.dat	not specified	not checked	/usr/smith/file.dat

When the resulting file pathname begins with a tilde character (~), C-shell-style pathname substitution is used (regardless of what shell is being used), such as a top-level directory (below the root). For additional information on tilde pathname substitution, see csh(1).

Rules for Applying Default Pathnames and File Names

Intel Fortran determines the file name and the directory path based on certain rules. It determines a file name string as follows:

- If the FILE specifier is present, its value is used.
- If the FILE specifier is not present, Intel Fortran examines the corresponding environment variable. If the corresponding environment variable is set, that value is used. If the corresponding environment variable is not set, a file name in the form fort.*n* is used.

Once Intel Fortran determines the resulting file name string, it determines the directory (which optionally precedes the file name) as follows:

- If the resulting file name string contains an absolute pathname, it is used and the DEFAULTFILE specifier, environment variable, and current directory values are ignored.
- If the resulting file name string does not contain an absolute pathname, Intel Fortran examines the DEFAULTFILE specifier and current directory value: If the corresponding environment variable is set and specifies an absolute pathname, that value is used. Otherwise, the DEFAULTFILE specifier value, if present, is used. If the DEFAULTFILE specifier is not present, Intel Fortran uses the current directory as an absolute pathname.

Opening Files: OPEN Statement

To open a file, you can use a preconnected file (as described in Logical Devices) or can open a file with an OPEN statement. The OPEN statement lets you specify the file connection characteristics and other information.

OPEN Statement Specifiers

The OPEN statement connects a unit number with an external file and allows you to explicitly specify file attributes and run-time options using OPEN statement specifiers. Once you open a file, you should close it before opening it again unless it is a preconnected file.

If you open a unit number that was opened previously (without being closed), one of the following occurs:

- If you specify a file specification that does not match the one specified for the original open, the Intel Fortran run-time system closes the original file and then opens the second file. This resets the current record position for the second file.
- If you specify a file specification that matches the one specified for the original open, the file is reconnected without the internal equivalent of the CLOSE and OPEN. This lets you change one or more OPEN statement run-time specifiers while maintaining the record position context.

You can use the INQUIRE Statement to obtain information about whether or not a file is opened by your program.

Especially when creating a new file using the OPEN statement, examine the defaults (see the description of the OPEN statement) or explicitly specify file attributes with the appropriate OPEN statement specifiers.

Specifiers for File and Unit Information

These specifiers identify file and unit information:

- UNIT specifies the logical unit number.
- NEWUNIT specifies that the Intel® Fortran run-time library should select an unused logical unit number.
- FILE (or NAME) and DEFAULTFILE specify the directory and/or file name of an external file.
- STATUS or TYPE indicates whether to create a new file, overwrite an existing file, open an existing file, or use a scratch file.
- STATUS or DISPOSE specifies the file existence status after CLOSE.

Specifiers for File and Record Characteristics

These specifiers identify file and record characteristics:

- ORGANIZATION indicates the file organization (sequential or relative).
- RECORDTYPE indicates which record type to use.
- FORM indicates whether records are formatted or unformatted.
- CARRIAGECONTROL indicates the terminal control type.
- RECL or RECORDSIZE specifies the record size.

Specifier for Special File Open Routine

USEROPEN names the routine that will open the file to establish special context that changes the effect of subsequent Intel Fortran I/O statements.

Specifiers for File Access, Processing, and Position

These specifiers identify file access, processing, and position:

- ACCESS indicates the access mode (direct, sequential, or stream).
- SHARED sets file locking for shared access. Indicates that other users can access the same file.
- NOSHARED sets file locking for exclusive access. Indicates that other users who use file locking mechanisms cannot access the same file.
- SHARE specifies shared or exclusive access; for example, SHARE='DENYNONE' or SHARE='DENYRW'.
- POSITION indicates whether to position the file at the beginning of file, before the end-of-file record, or leave it as is (unchanged).
- ACTION or READONLY indicates whether statements will be used to only read records, only write records, or both read and write records.
- MAXREC specifies the maximum record number for direct access.
- ASSOCIATEVARIABLE specifies the variable containing the next record number for direct access.
- ASYNCHRONOUS specifies whether input/output should be performed asynchronously.

Specifiers for Record Transfer Characteristics

These specifiers identify record transfer characteristics:

- BLANK indicates whether to ignore blanks in numeric fields.
- DELIM specifies the delimiter character for character constants in list-directed or namelist output.
- PAD, when reading formatted records, indicates whether padding characters should be added if the item list and format specification require more data than the record contains.
- BUFFERED indicates whether buffered or non-buffered I/O should be used.
- BLOCKSIZE specifies the physical I/O buffer or transfer size.
- BUFFERCOUNT specifies the number of physical I/O buffers.
- CONVERT specifies the format of unformatted numeric data.

Specifiers for Error-Handling Capabilities

These specifiers are used for error handling:

- ERR specifies a label to branch to if an error occurs.
- IOSTAT specifies the integer variable to receive the error (IOSTAT) number if an error occurs.

Specifier for File Close Action

DISPOSE identifies the action to take when the file is closed.

Specifying File Locations in an OPEN Statement

You can use the FILE and DEFAULTFILE specifiers of the OPEN statement to specify the complete definition of a particular file to be opened on a logical unit. (The Language Reference Manual describes the OPEN statement in greater detail.)

For example:

```
OPEN (UNIT=4, FILE='/usr/users/smith/test.dat', STATUS='OLD')
```

The file `test.dat` in directory `/usr/users/smith` is opened on logical unit 4. No defaults are applied, because both the directory and file name were specified. The value of the FILE specifier can be a character constant, variable, or expression.

In the following interactive example, the user supplies the file name and the DEFAULTFILE specifier supplies the default values for the full pathname string. The file to be opened is located in `/usr/users/smith` and is concatenated with the file name typed by the user into the variable DOC:

```
CHARACTER(LEN=9) DOC
WRITE (6,*)  'Type file name '
READ (5,*) DOC
OPEN (UNIT=2, FILE=DOC, DEFAULTFILE='/usr/users/smith',STATUS='OLD')
```

A slash (backslash on Windows systems) is appended to the end of the default file string if it does not have one.

Obtaining File Information: INQUIRE Statement

The INQUIRE statement returns information about a file and has the following forms:

- Inquiry by unit
- Inquiry by file name
- Inquiry by output item list
- Inquiry by directory

Inquiry by Unit

An inquiry by unit is usually done for an opened (connected) file. An inquiry by unit causes the Intel® Fortran RTL to check whether the specified unit is connected or not. One of the following occurs, depending on whether the unit is connected or not:

If the unit is connected:

- The EXIST and OPENED specifier variables indicate a true value.
- The pathname and file name are returned in the NAME specifier variable (if the file is named).
- Other information requested on the previously connected file is returned.
- Default values are usually returned for the INQUIRE specifiers also associated with the OPEN statement.
- The RECL value unit for connected formatted files is always 1-byte units. For unformatted files, the RECL unit is 4-byte units, unless you specify the `-assume byterecl` option to request 1-byte units.

If the unit is not connected:

- The OPENED specifier indicates a false value.
- The unit NUMBER specifier variable is returned as a value of -1.
- Any other information returned will be undefined or default values for the various specifiers.

For example, the following INQUIRE statement shows whether unit 3 has a file connected (OPENED specifier) in logical variable I_OPENED, the name (case-sensitive) in character variable I_NAME, and whether the file is opened for READ, WRITE, or READWRITE access in character variable I_ACTION:

```
INQUIRE (3, OPENED=I_OPENED, NAME=I_NAME, ACTION=I_ACTION)
```

Inquiry by File Name

An inquiry by name causes the Intel Fortran RTL to scan its list of open files for a matching file name. One of the following occurs, depending on whether a match occurs or not:

If a match occurs:

- The EXIST and OPENED specifier variables indicate a true value.
- The pathname and file name are returned in the NAME specifier variable.
- The UNIT number is returned in the NUMBER specifier variable.
- Other information requested on the previously connected file is returned.
- Default values are usually returned for the INQUIRE specifiers also associated with the OPEN statement.

- The RECL value unit for connected formatted files is always 1-byte units. For unformatted files, the RECL unit is 4-byte units, unless you specify the `-assume byterecl` option to request 1-byte units.

If no match occurs:

- The OPENED specifier variable indicates a false value.
- The unit NUMBER specifier variable is returned as a value of -1.
- The EXIST specifier variable indicates (true or false) whether the named file exists on the device or not.
- If the file does exist, the NAME specifier variable contains the pathname and file name.
- Any other information returned will be default values for the various specifiers, based on any information specified when calling INQUIRE.

The following INQUIRE statement returns whether the file named log_file is connected in logical variable I_OPEN, whether the file exists in logical variable I_EXIST, and the unit number in integer variable I_NUMBER:

```
INQUIRE (FILE='log_file', OPENED=I_OPEN, EXIST=I_EXIST, NUMBER=I_NUMBER)
```

Inquiry by Output Item List

Unlike inquiry by unit or inquiry by name, inquiry by output item list does not attempt to access any external file. It returns the length of a record for a list of variables that would be used for unformatted WRITE, READ, and REWRITE statements. The following INQUIRE statement returns the maximum record length of the variable list in variable I_RECLENGTH. This variable is then used to specify the RECL value in the OPEN statement:

```
INQUIRE (IOLENGTH=I_RECLENGTH) A, B, H
OPEN (FILE='test.dat', FORM='UNFORMATTED', RECL=I_RECLENGTH, UNIT=9)
```

For an unformatted file, the IOLENGTH value is returned using 4-byte units, unless you specify the `-assume byterecl` option to request 1-byte units.

Inquiry by Directory

An inquiry by directory verifies that a directory exists.

If the directory exists:

- The EXIST specifier variable indicates a true value.
- The full directory pathname is returned in the DIRSPEC specifier variable.

If the directory does not exist:

- The EXIST specified variable indicates a false value.
- The value of the DIRSPEC specifier variable is unchanged.

For example, the following INQUIRE statement returns the full directory pathname:

```
LOGICAL        ::L_EXISTS
CHARACTER (255)::C_DIRSPEC
INQUIRE (DIRECTORY=".", DIRSPEC=C_DIRSPEC, EXIST=L_EXISTS)
```

The following INQUIRE statement verifies that a directory does not exist:

```
INQUIRE (DIRECTORY="I-DO-NOT-EXIST", EXIST=L_EXISTS)
```

Closing Files: CLOSE Statement

Usually, any external file opened should be closed by the same program before it completes. The CLOSE statement flushes any output buffers and disconnects the unit and its external file. You must specify the unit number (UNIT specifier) to be closed.

You can also specify:

- Whether the file should be deleted or kept (STATUS specifier)
- Error handling information (ERR and IOSTAT specifiers)

To delete a file when closing it:

- In the OPEN statement, specify the ACTION keyword (such as ACTION='READ'). Avoid using the READONLY keyword, because a file opened using the READONLY keyword cannot be deleted when it is closed.
- In the CLOSE statement, specify the keyword STATUS='DELETE'.

If you opened an external file and did an inquire by unit, but do not like the default value for the ACCESS specifier, you can close the file and then reopen it, explicitly specifying the ACCESS desired.

Typically, it is not necessary to close preconnected units. Internal files are neither opened nor closed.

Record I/O Statement Specifiers

After you open a file or use a preconnected file, you can use the following statements:

- READ, WRITE, ACCEPT, and PRINT to perform record I/O.
- BACKSPACE, ENDFILE, and REWIND to set record position within the file.
- DELETE, REWRITE, TYPE, and FIND to perform various operations.

The record I/O statement must use the appropriate record I/O form (formatted, list-directed, namelist, or unformatted).

You can use the following specifiers with the READ and WRITE record I/O statements:

- UNIT specifies the unit number to or from which input or output will occur.
- END specifies a label to branch to if end-of-file occurs; only applies to input statements on sequential files.
- ERR specifies a label to branch to if an error occurs.
- IOSTAT specifies an integer variable to contain the error number if an error occurs.
- FMT specifies a label of a FORMAT statement or character data specifying a FORMAT.
- NML specifies the name of a NAMELIST.
- REC specifies a record number for direct access.

When using nonadvancing I/O, use the ADVANCE, EOR, and SIZE specifiers.

When using the REWRITE statement, you can use the UNIT, FMT, ERR, and IOSTAT specifiers.

File Sharing (Linux* and macOS*)

This topic only applies to Linux* and macOS* operating systems.

Depending on the value specified by the ACTION (or READONLY) specifier in the OPEN statement, the file will be opened by your program for reading, writing, or both reading and writing records. This simply checks that the program itself executes the type of statements intended.

File locking mechanisms allow users to enable or restrict access to a particular file when that file is being accessed by another process.

Intel® Fortran file locking features provide three file access modes:

- Implicit Shared mode, which occurs when no mode is specified. This is also called No Locking.
- Explicit Shared mode, when all cooperating processes have access to a file. This mode is set in the OPEN statement by the SHARED specifier or the SHARE='DENYNONE' specifier.
- Exclusive mode, when only one process has access to a file. This mode is set in the OPEN statement by the NOSHARED specifier or the SHARE='DENYRW' specifier.

The file locking mechanism looks for explicit setting of the corresponding specifier in the OPEN statement. Otherwise, the Fortran run time does not perform any setting or checking for file locking and the process can access the file regardless of the fact that other processes have already opened or locked the file.

Example 1: Implicit Shared Mode (No Locking)

Process 1 opens the file without a specifier, resulting in no locking.

Process 2 now tries to open the file:

- It gains access regardless of the mode it is using.

Example 2: Explicit Shared Mode

Process 1 opens the file with Explicit Shared mode.

Process 2 now tries to open the file:

- If process 2 opens the file with Explicit Shared mode or Implicit Shared (No Locking) mode, it gets access to the file.
- If process 2 opens the file with Exclusive mode, it receives an error.

Example 3: Exclusive Mode

Process 1 opens the file with Exclusive mode.

Process 2 now tries to open the file:

- If process 2 opens the file with Implicit Shared (No Locking) mode, it gets access to the file.
- If process 2 opens the file with Explicit Shared or Exclusive mode, it receives an error.

The Fortran runtime does not coordinate file entry updates during cooperative access. The user needs to coordinate access times among cooperating processes to handle the possibility of simultaneous WRITE and REWRITE statements on the same record positions.

Specifying the Initial Record Position

When you open a disk file, you can use the OPEN statement POSITION specifier to request one of the following initial record positions within the file:

- The initial position before the first record (POSITION='REWIND')

  A sequential access READ or WRITE statement will read or write the first record in the file.
- A point beyond the last record in the file (POSITION='APPEND'), just before the end-of-file record, if one exists

  For a new file, this is the initial position before the first record (same as 'REWIND'). You might specify 'APPEND' before you write records to an existing sequential file using sequential access.
- The current position (POSITION='ASIS')

  This is usually used only to maintain the current record position when reconnecting a file. The second OPEN specifies the same unit number and specifies the same file name (or omits it), which leaves the file open, retaining the current record position. However, if the second OPEN specifies a different file name for the same unit number, the current file will be closed and the different file will be opened.

The following I/O statements allow you to change the current record position:

- REWIND sets the record position to the initial position before the first record. A sequential access READ or WRITE statement would read or write the first record in the file.
- BACKSPACE sets the record position to the previous record in a file. Using sequential access, if you wrote record 5, issued a BACKSPACE to that unit, and then read from that unit, you would read record 5.
- ENDFILE writes an end-of-file marker. This is typically done after writing records using sequential access just before you close the file.

Unless you use nonadvancing I/O, reading and writing records usually advances the current record position by one record. More than one record might be transferred using a single record I/O statement.

Advancing and Nonadvancing Record I/O

After you open a file, if you omit the ADVANCE specifier (or specify ADVANCE= 'YES') in READ and WRITE statements, advancing I/O (normal Fortran I/O) will be used for record access. When using advancing I/O:

- Record I/O statements transfer one entire record (or multiple records).
- Record I/O statements advance the current record position to a position before the next record.

You can request nonadvancing I/O for the file by specifying the ADVANCE= 'NO' specifier in a READ and WRITE statement. You can use nonadvancing I/O only for sequential access to external files using formatted I/O (not list-directed or namelist).

When you use nonadvancing I/O, the current record position does not change, and part of the record might be transferred, unlike advancing I/O where one or more entire records are always transferred.

You can alternate between advancing and nonadvancing I/O by specifying different values for the ADVANCE specifier ('YES' and 'NO') in the READ and WRITE record I/O statements.

When reading records with either advancing or nonadvancing I/O, you can use the END specifier to branch to a specified label when the end of the file is read.

Because nonadvancing I/O might not read an entire record, it also supports an EOR specifier to branch to a specified label when the end of the record is read. If you omit the EOR and the IOSTAT specifiers when using nonadvancing I/O, an error results when the end-of-record is read.

When using nonadvancing input, you can use the SIZE specifier to return the number of characters read. For example, in the following READ statement, SIZE=X (where variable X is an integer) returns the number of characters read in X and an end-of-record condition causes a branch to label 700:

```
150 FORMAT (F10.2, F10.2, I6)
    READ (UNIT=20, FMT=150, SIZE=X, ADVANCE='NO', EOR=700) A, F, I
```

User-Supplied OPEN Procedures: USEROPEN Specifier

You can use the USEROPEN specifier in an OPEN statement to pass control to a routine that directly opens a file. The called routine can use system calls or library routines to open the file and may establish special context that changes the effect of subsequent I/O statements.

The Intel® Fortran Run-Time Library (RTL) I/O support routines call the USEROPEN function in place of the system calls usually used when the file is first opened for I/O. The USEROPEN specifier in an OPEN statement specifies the name of a function to receive control.

The called function must open a file (or pipe) and return the file descriptor of the file (or pipe) it has opened when control is returned to the RTL. The called function may specify different options when it opens the file than a normal OPEN statement would. It may specify a different file.

You can obtain the file descriptor from the Intel® Fortran RTL for a specific unit number by using the PXFFILENO routine.

Although the called function can be written in other languages (such as Fortran), C is usually the best choice for making system calls, such as open or create.

NOTE
If your application requires that you use C to perform the file open and close, as well as all record operations, call the appropriate C procedure from the Intel® Fortran program without using the Fortran OPEN statement.

NOTE
If a filename has been specified in the OPEN statement that included the USEROPEN specifier, any subsequent CLOSE statement specifying STATUS=DELETE (or DISPOSE=DELETE) only acts on the filename specified in the OPEN statement. If you specified a different filename in the function named in USEROPEN, the CLOSE statement will have no effect on that filename.

Syntax and Behavior of the USEROPEN Specifier

The USEROPEN specifier for the OPEN statement has the form:

USEROPEN = *function-name*

The *function-name* represents the name of an external function. The external function can be written in Fortran, C, or other languages.

The return value is the *file descriptor*. If an error occurs in the function, it should return -1.

In the calling program, the function must be declared in an EXTERNAL statement. For example, the following Intel® Fortran code can be used to call the USEROPEN procedure UOPEN (known to the linker as `uopen_`):

```
EXTERNAL  UOPEN
INTEGER   UOPEN
.
.
.
OPEN (UNIT=10, FILE='/usr/test/data', STATUS='NEW', USEROPEN=UOPEN)
```

During the execution of the OPEN statement, the external procedure called `uopen_` receives control. The function opens the file, may perform other operations, and subsequently returns control (with the file descriptor) to the RTL. You can use other system calls or library routines within the USEROPEN function.

In most cases, the USEROPEN function modifies the open flags argument passed by the Intel® Fortran RTL or uses a new value before the open (or create) system call. After the function opens the file, it must return control to the RTL.

On Linux and macOS*, the *file descriptor* is a 4-byte integer on both 32-bit and 64-bit systems. On Windows, the *file descriptor* is a 4-byte integer on 32-bit systems and an 8-byte integer on 64-bit systems:

- If the USEROPEN function is written in C, declare it as a C function.
- If the USEROPEN function is written in Fortran, declare it as a FUNCTION, perhaps with an interface block.

The called function must return the *file descriptor* to the RTL, or -1 if the function detects an error .

The following shows the available arguments and definitions for Linux* and macOS*, and then for Windows*:

Linux* and macOS* Arguments and Definitions:

```
int   uopen_ (          (1)
char  *file_name,       (2)
int   *open_flags,      (3)
int   *create_mode,     (4)
int   *lun,             (5)
int   file_length);     (6)
```

On Linux* and macOS* systems, the function definition and the arguments passed from the Intel® Fortran RTL are as follows:

1. The function must be declared as a 4-byte integer (int).
2. Indicates the pathname to be opened; the pathname includes the file name.
3. Indicates the open flags. The open flags are described in the header file `/usr/include/sys/file.h` or open(2).

4. Indicates the create mode, which is the protection needed when creating a Linux* OS-style file. The create modes are described in open(2).
5. Indicates the logical unit number.
6. Indicates the pathname length (hidden character length argument of the pathname).

Argument Notes for Linux* and macOS*:

The open system call (see open(2)) requires the passed pathname, the open flags (which define the type access needed, whether the file exists, and so on), and the create mode. The logical unit number specified in the OPEN statement is passed in case the USEROPEN function needs it. The hidden character length of the pathname is also passed.

Windows* Arguments and Definitions:

```
int uopen_ (                              (1)
char   *filename,                         (2)
int    *desired_access,                   (3)
int    *share_mode,                       (4)
int     a_null,          /* always 0 */   (5)
int    *flags_attr,                       (6)
int     b_null,          /* always 0 */   (7)
int    *unit,                             (8)
int    *flen);                            (9)
```

On Windows* systems, the function definition and the arguments passed from the Intel® Fortran RTL are as follows:

1. The function must be declared as a 4-byte integer (int) on 32-bit systems and an 8-byte integer (long long int) on 64-bit systems.
2. Indicates the pathname to be opened; the pathname includes the file name.
3. Indicates the mode of access. It can be set to read, write, or read/write.
4. Indicates the file protection mode.
5. This is a NULL that is passed as a literal zero by value.
6. This sets flags that specify file modes and several kinds of file features (such as whether to use sequential access or random access, whether to delete on close, etc.)
7. This is a NULL that is passed as a literal zero by value.
8. Indicates the logical unit number.
9. Indicates the pathname length (the hidden character length argument of the pathname).

Argument Notes for Windows*:

The argument list for a USEROPEN routine on Windows is very similar to the argument list for the Microsoft* Windows function CreateFile. This lets you easily write a USEROPEN routine and pass the input arguments to a call to CreateFile. The CreateFile system call requires the filename, the desired_access, the shared_mode, and the flags_attr. These arguments have been set to reflect the file semantics requested in the OPEN statement. The logical unit number specified in the OPEN statement is passed in case the USEROPEN function needs it. The hidden character length of the pathname is also passed.

On 32-bit Windows*, a Fortran USEROPEN function must use the default "C, Reference" calling convention. If you have used the `iface` compiler option to change the default calling convention to "stdcall" or "cvf", you will need to add a !DIR$ ATTRIBUTES DEFAULT directive in the function source to have it use the correct calling convention.

Restrictions of Called USEROPEN Functions

The Intel® Fortran RTL uses exactly one file descriptor per logical unit, which must be returned by the called function. Because of this, only certain system calls or library routines can be used to open the file.

On Linux* systems, system calls and library routines which do not return a file descriptor include `mknod` (see `mknod(2)`) and `fopen` (see `fopen(3)`). For example, the `fopen` routine returns a file pointer instead of a file descriptor.

The following Intel® Fortran code calls the USEROPEN function named UOPEN:

```
EXTERNAL  UOPEN
INTEGER   UOPEN
.
.
.
OPEN (UNIT=1,FILE='ex1.dat',STATUS='NEW',USEROPEN=UOPEN,
ERR=9,IOSTAT=errnum)
```

If UOPEN is a Fortran function, its name is decorated appropriately for Fortran.

Likewise, if UOPEN is a C function, its name is decorated appropriately for C, as long as the following line is included in the above code:

```
!DIR$ ATTRIBUTES C::UOPEN
```

Compiling and Linking the C and Intel® Fortran Programs

Use the `icc` or `icl` command to compile the called `uopen` C function `uopen.c`, and the `ifort` command to compile the Intel® Fortran calling program `ex1.f`. The same `ifort` command also links both object files by using the appropriate libraries:

```
icc -c uopen.c (Linux* OS)
icl -c uopen.c (Windows* OS)
ifort ex1.f uopen.o
```

Examples

The following shows an example on Linux and macOS* systems and an example on Windows systems.

Example on Linux and macOS* systems:

```
      PROGRAM UserOpenMain
      IMPLICIT NONE

      EXTERNAL      UOPEN
      INTEGER(4)    UOPEN

      CHARACTER(10) :: FileName="UOPEN.DAT"
      INTEGER       :: IOS
      CHARACTER(255):: InqFullName
      CHARACTER(100):: InqFileName
      INTEGER       :: InqLun
      CHARACTER(30) :: WriteOutBuffer="Write_One_Record_to_the_File. "
      CHARACTER(30) :: ReadInBuffer  ="??????????????????????????????"

110   FORMAT( X,"FortranMain: ",A," Created (iostat=",I0,")")
115   FORMAT( X,"FortranMain: ",A,": Creation Failed (iostat=",I0,")")
120   FORMAT( X,"FortranMain: ",A,": ERROR: INQUIRE Returned Wrong FileName")
130   FORMAT( X,"FortranMain: ",A,": ERROR: ReadIn and WriteOut Buffers Do Not Match")

      WRITE(*,'(X,"FortranMain: Test the USEROPEN Facility of Open")')

      OPEN(UNIT=10,FILE='UOPEN.DAT',STATUS='REPLACE',USEROPEN=UOPEN, &
           IOSTAT=ios, ACTION='READWRITE')
```

```
!     When the OPEN statement is executed, the uopen_ function receives control.
!     The uopen_ function opens the file by calling open(), and subsequently
!     returns control with the handle returned by open().

      IF (IOS .EQ. 0)  THEN
         WRITE(*,110) TRIM(FileName), IOS
         INQUIRE(10, NAME=InqFullName)
         CALL ParseForFileName(InqFullName,InqFileName)
         IF (InqFileName .NE. FileName) THEN
             WRITE(*,120) TRIM(FileName)
         END IF
      ELSE
         WRITE(*,115) TRIM(FileName), IOS
         GOTO 9999
      END IF

      WRITE(10,*) WriteOutBuffer
      REWIND(10)
      READ(10,*) ReadInBuffer
      IF (ReadinBuffer .NE. WriteOutbuffer) THEN
         WRITE(*,130) TRIM(FileName)
      END IF

      CLOSE(10)
      WRITE(*,'(X,"FortranMain: Test of USEROPEN Completed")')

9999  CONTINUE
      END

!-----------------------------------------------------------------
! SUBROUTINE: ParseForFileName
!             Takes a full pathname and returns the filename
!             with its extension.
!-----------------------------------------------------------------
      SUBROUTINE ParseForFileName(FullName,FileName)

      CHARACTER(255):: FullName
      CHARACTER(255):: FileName
      INTEGER       :: P

      P = INDEX(FullName,'/',.TRUE.)
      FileName = FullName(P+1:)

      END

//
// File: UserOpen_Sub.c
//
// This routine opens a file using data passed from the Intel(c) Fortran OPEN statement.
//

#include <stdio.h>
#include <stdlib.h>
#include <fcntl.h>
#include <sys/types.h>
#include <sys/stat.h>
#include <sys/file.h>
```

```
#include <errno.h>
int uopen_ ( char *file_name,   /* access read: name of the file to open (null terminated) */
             int  *open_flags,  /* access read: READ/WRITE, see file.h or open(2) */
             int  *create_mode, /* access read: set if the file is to be created */
             int  *unit_num,    /* access read: logical unit number to be opened */
             int  filenam_len ) /* access read: number of characters in file_name */
{
    /*
    ** The returned value is the following:
    **    value != -1 is a valid file descriptor
    **    value == -1 is returned on an error
    */
    int return_value;

    printf(" %s: Opening FILENAME = %s\n", __FILE__, file_name);
    printf(" %s: open_flags = 0x%8.8x\n", __FILE__, *open_flags);
    if ( *open_flags & O_CREAT ) {
        printf(" %s: the file is being created, create_mode = 0x%8.8x\n", __FILE__,
*create_mode);
    }

    printf(" %s: open() ", __FILE__);
    return_value = open(file_name, *open_flags, *create_mode);
    if (return_value != 0) {
        printf("FAILED.\n");
        return_value = -1;
    } else {
        printf("SUCCEEDED.\n");
    }

    return (return_value);
} /* end of uopen_() */
```

Example on Windows systems:

In the calling Fortran program, the function named in USEROPEN must first be declared in an EXTERNAL statement. For example, the following Fortran code might be used to call the USEROPEN procedure UOPEN:

```
 IMPLICIT INTEGER (A-Z)
 EXTERNAL UOPEN
 INTEGER(INT_PTR_KIND()) UOPEN
 ...
 OPEN(UNIT=10,FILE='UOPEN.DAT',STATUS='NEW',USEROPEN=UOPEN)
```

When the OPEN statement is executed, the UOPEN function receives control. The function opens the file by calling CreateFile( ), performs whatever operations were specified, and subsequently returns control (with the *handle* returned by CreateFile( )) to the calling Fortran program.

Here is what the UOPEN function might look like:

```
       INTEGER(INT_PTR_KIND()) FUNCTION UOPEN( FILENAME,      &
                               DESIRED_ACCESS, &
                               SHARE_MODE,     &
                               A_NULL,         &
                               CREATE_DISP,    &
                               FLAGS_ATTR,     &
                               B_NULL,         &
                               UNIT,           &
                               FLEN )
```

```
       !DIR$ ATTRIBUTES C, ALIAS:'_UOPEN' :: UOPEN
       !DIR$ ATTRIBUTES REFERENCE :: FILENAME
       !DIR$ ATTRIBUTES REFERENCE :: DESIRED_ACCESS
       !DIR$ ATTRIBUTES REFERENCE :: SHARE_MODE
       !DIR$ ATTRIBUTES REFERENCE :: CREATE_DISP
       !DIR$ ATTRIBUTES REFERENCE :: FLAGS_ATTR
       !DIR$ ATTRIBUTES REFERENCE :: UNIT

       USE IFWIN
       IMPLICIT INTEGER (A-Z)
       CHARACTER*(FLEN) FILENAME
       TYPE(T_SECURITY_ATTRIBUTES), POINTER :: NULL_SEC_ATTR

! Set the FILE_FLAG_WRITE_THROUGH bit in the flag attributes to CreateFile( )
! (for whatever reason)
       FLAGS_ATTR = FLAGS_ATTR + FILE_FLAG_WRITE_THROUGH

! Do the CreateFile( ) call and return the status to the Fortran rtl
       STS = CreateFile( FILENAME,            &
                         DESIRED_ACCESS,      &
                         SHARE_MODE,          &
                         NULL_SEC_ATTR,       &
                         CREATE_DISP,         &
                         FLAGS_ATTR,          &
                         0 )

       UOPEN = STS
       RETURN
       END
```

The UOPEN function is declared to use the cdecl calling convention, so it matches the Fortran rtl declaration of a useropen routine.

The following function definition and arguments are passed from the Intel Fortran Run-time Library to the function named in USEROPEN:

```
       INTEGER(INT_PTR_KIND()) FUNCTION UOPEN( FILENAME,       &
                               DESIRED_ACCESS, &
                               SHARE_MODE,     &
                               A_NULL,         &
                               CREATE_DISP,    &
                               FLAGS_ATTR,     &
                               B_NULL,         &
                               UNIT,           &
                               FLEN )
       !DIR$ ATTRIBUTES C, ALIAS:'_UOPEN' :: UOPEN
       !DIR$ ATTRIBUTES REFERENCE :: DESIRED_ACCESS
       !DIR$ ATTRIBUTES REFERENCE :: SHARE_MODE
       !DIR$ ATTRIBUTES REFERENCE :: CREATE_DISP
       !DIR$ ATTRIBUTES REFERENCE :: FLAGS_ATTR
       !DIR$ ATTRIBUTES REFERENCE :: UNIT
```

The first 7 arguments correspond to the CreateFile( ) api arguments. The value of these arguments is set according the caller's OPEN( ) arguments:

FILENAME	Is the address of a null terminated character string that is the name of the file.

DESIRED_ACCESS	Is the desired access (read-write) mode passed by reference.
SHARE_MODE	Is the file sharing mode passed by reference.
A_NULL	Is always null. The Fortran runtime library always passes a NULL for the pointer to a SECURITY_ATTRIBUTES structure in its CreateFile( ) call.
CREATE_DISP	Is the creation disposition specifying what action to take on files that exist, and what action to take on files that do not exist. It is passed by reference.
FLAGS_ATTR	Specifies the file attributes and flags for the file. It is passed by reference.
B_NULL	Is always null. The Fortran runtime library always passes a NULL for the handle to a template file in it's CreateFile( ) call.

The last 2 arguments are the Fortran unit number and length of the file name:

UNIT	Is the Fortran unit number on which this OPEN is being done. It is passed by reference.
FLEN	Is the length of the file name, not counting the terminating null, and passed by value.

Microsoft Fortran PowerStation Compatible Files (Windows*)

This topic only applies to Windows*.

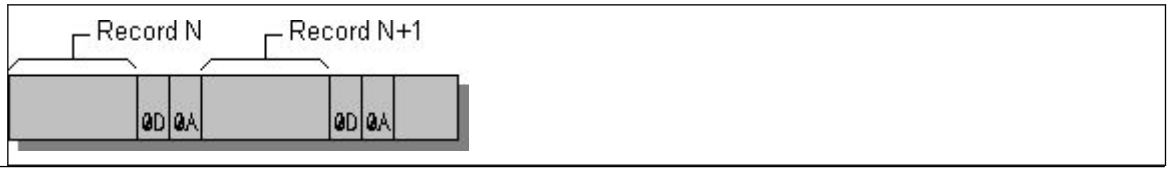
When using the `fpscomp` option for Microsoft* Fortran PowerStation compatibility, the following types of files are possible:

- Formatted Sequential
- Formatted Direct
- Unformatted Sequential
- Unformatted Direct
- Binary Sequential
- Binary Direct

Formatted Sequential Files

A formatted sequential file is a series of formatted records written sequentially and read in the order in which they appear in the file. Records can vary in length and can be empty. They are separated by carriage return (0D) and line feed (0A) characters as shown in the following figure.

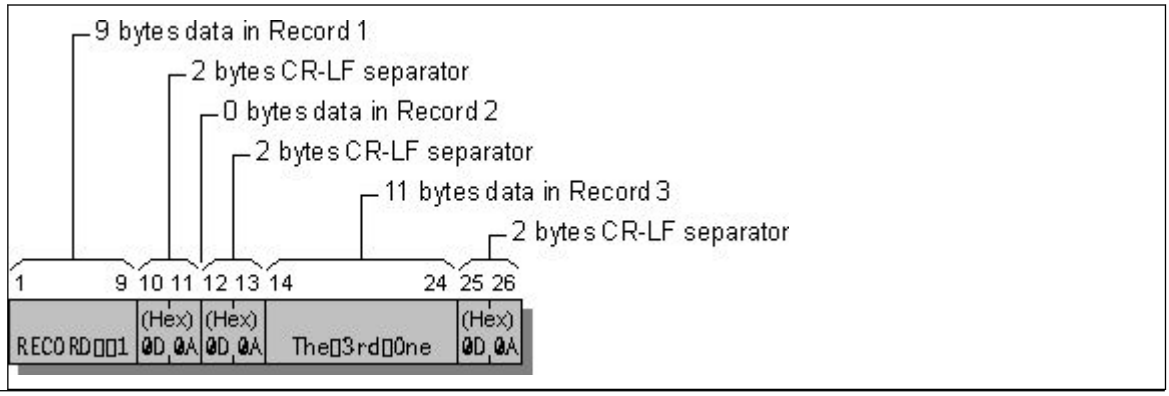
Formatted Records in a Formatted Sequential File



An example of a program writing three records to a formatted sequential file is given below. The resulting file is shown in the following figure.

```
  OPEN (3, FILE='FSEQ')
! FSEQ is a formatted sequential file by default.
  WRITE (3, '(A, I3)') 'RECORD', 1
  WRITE (3, '()')
  WRITE (3, '(A11)') 'The 3rd One'
  CLOSE (3)
  END
```

Formatted Sequential File



Formatted Direct Files

In a formatted direct file, all of the records are the same length and can be written or read in any order. The record size is specified with the RECL option in an OPEN statement and should be equal to or greater than the number of bytes in the longest record.

The carriage return (CR) and line feed (LF) characters are record separators and are not included in the RECL value. Once a direct-access record has been written, you cannot delete it, but you can rewrite it.

During output to a formatted direct file, if data does not completely fill a record, the compiler pads the remaining portion of the record with blank spaces. The blanks ensure that the file contains only completely filled records, all of the same length. During input, the compiler by default also adds filler bytes (blanks) to the input record if the input list and format require more data than the record contains.

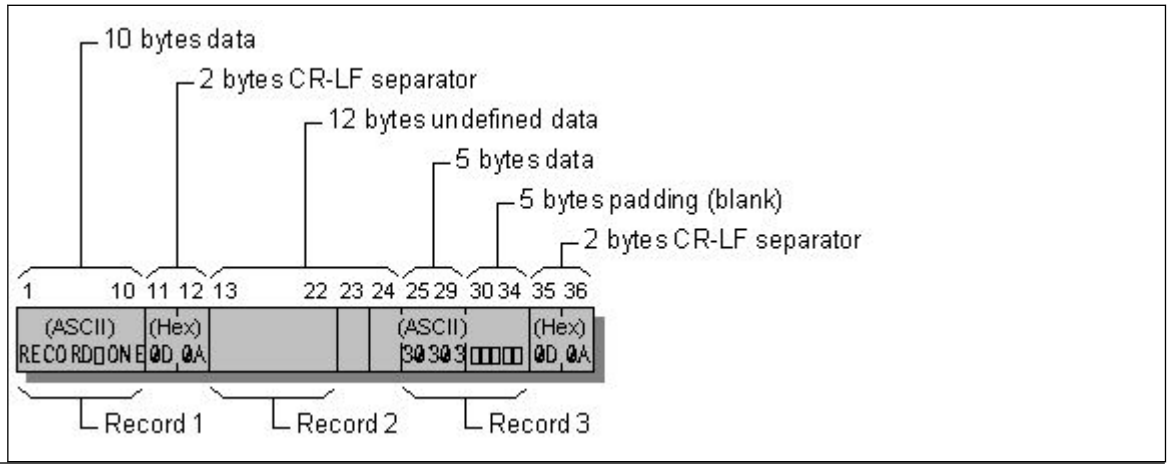
You can override the default blank padding on input by setting PAD='NO' in the OPEN statement for the file. If PAD='NO', the input record must contain the amount of data indicated by the input list and format specification. Otherwise, an error occurs. PAD='NO' has no effect on output.

An example of a program writing two records, record one and record three, to a formatted direct file is given below. The result is shown in the following figure.

```
OPEN (3,FILE='FDIR', FORM='FORMATTED', ACCESS='DIRECT',RECL=10)
WRITE (3, '(A10)', REC=1) 'RECORD ONE'
```

```
WRITE (3, '(I5)', REC=3) 30303
CLOSE (3)
END
```

Formatted Direct File



Unformatted Sequential Files

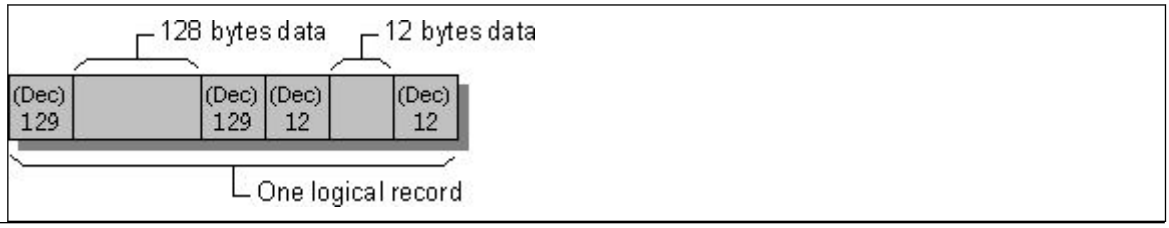
Unformatted sequential files are organized slightly differently on different platforms. This section describes unformatted sequential files created by Intel® Fortran when the `fpscomp` option is specified.

The records in an unformatted sequential file can vary in length. Unformatted sequential files are organized in chunks of 130 bytes or less called *physical blocks*. Each physical block consists of the data you send to the file (up to 128 bytes) plus two 1-byte "length bytes" inserted by the compiler. The length bytes indicate where each record begins and ends.

A *logical record* refers to an unformatted record that contains one or more physical blocks. (See the following figure.) Logical records can be as big as you want; the compiler will use as many physical blocks as necessary.

When you create a logical record consisting of more than one physical block, the compiler sets the length byte to 129 to indicate that the data in the current physical block continues on into the next physical block. For example, if you write 140 bytes of data, the logical record has the structure shown in the following figure.

Logical Record in Unformatted Sequential File



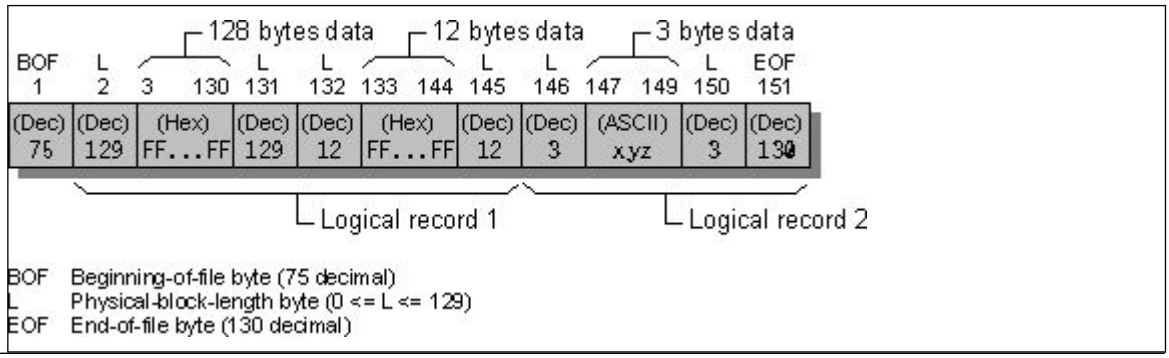
The first and last bytes in an unformatted sequential file are reserved; the first contains a value of 75, and the last holds a value of 130. Fortran uses these bytes for error checking and end-of-file references.

The following program creates the unformatted sequential file shown in the following figure:

```
!   Note: The file is sequential by default
!         -1 is FF FF FF FF hexadecimal.
```

```
!
  CHARACTER xyz(3)
  INTEGER(4) idata(35)
  DATA      idata /35 * -1/, xyz /'x', 'y', 'z'/
!
! Open the file and write out a 140-byte record:
! 128 bytes (block) + 12 bytes = 140 for IDATA, then 3 bytes for XYZ.
  OPEN (3, FILE='UFSEQ',FORM='UNFORMATTED')
  WRITE (3) idata
  WRITE (3) xyz
  CLOSE (3)
  END
```

Unformatted Sequential File



Unformatted Direct Files

An unformatted direct file is a series of unformatted records. You can write or read the records in any order you choose. All records have the same length, given by the RECL specifier in an OPEN statement. No delimiting bytes separate records or otherwise indicate record structure.

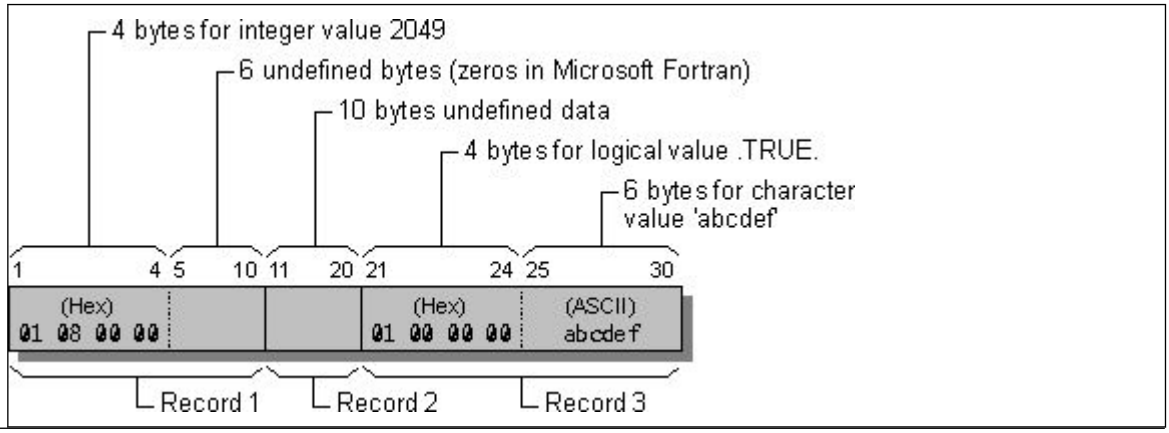
You can write a partial record to an unformatted direct file. Intel Fortran pads these records to the fixed record length with ASCII NULL characters. Unwritten records in the file contain undefined data.

The following program creates the sample unformatted direct file shown in the following figure:

```
OPEN (3, FILE='UFDIR', RECL=10,&
  & FORM = 'UNFORMATTED', ACCESS = 'DIRECT')
WRITE (3, REC=3) .TRUE., 'abcdef'
```

```
  WRITE (3, REC=1) 2049
  CLOSE (3)
  END
```

Unformatted Direct File



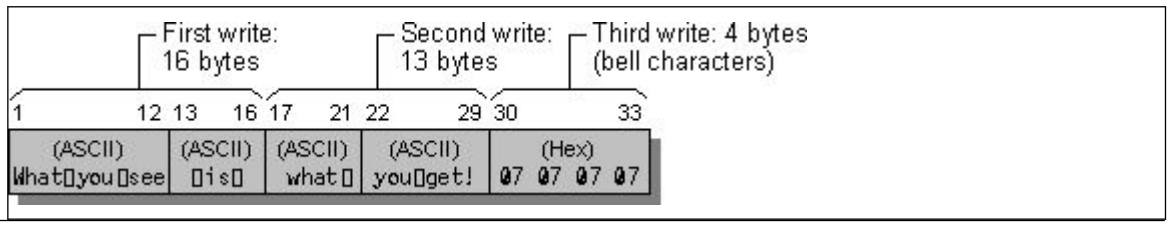
Binary Sequential Files

A binary sequential file is a series of values written and read in the same order and stored as binary numbers. No record boundaries exist, and no special bytes indicate file structure. Data is read and written without changes in form or length. For any I/O data item, the sequence of bytes in memory is the sequence of bytes in the file.

The next program creates the binary sequential file shown in the following figure:

```
!  NOTE: 07 is the bell character
!     Sequential is assumed by default.
!
  INTEGER(1) bells(4)
  CHARACTER(4) wys(3)
  CHARACTER(4) cvar
  DATA bells /4*7/
  DATA cvar /' is '/,wys /'What',' you',' see'/
  OPEN (3, FILE='BSEQ',FORM='BINARY')
  WRITE (3) wys, cvar
  WRITE (3) 'what ', 'you get!'
  WRITE (3) bells
  CLOSE (3)
  END
```

Binary Sequential File



Binary Direct Files

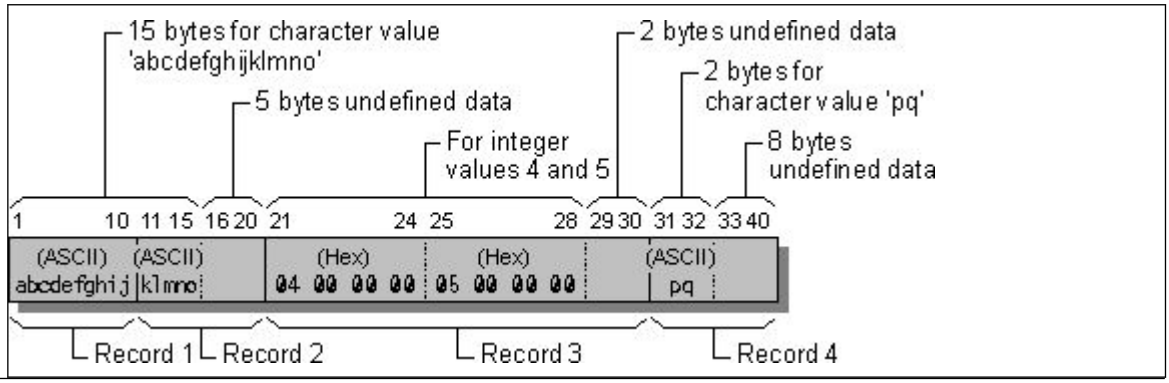
A binary direct file stores records as a series of binary numbers, accessible in any order. Each record in the file has the same length, as specified by the RECL argument to the OPEN statement. You can write partial records to binary direct files; any unused portion of the record will contain undefined data.

A single read or write operation can transfer more data than a record contains by continuing the operation into the next records of the file. Performing such an operation on an unformatted direct file would cause an error. Valid I/O operations for unformatted direct files produce identical results when they are performed on binary direct files, provided the operations do not depend on zero padding in partial records.

The following program creates the binary direct file shown in the following figure:

```
OPEN (3, FILE='BDIR',RECL=10,FORM='BINARY',ACCESS='DIRECT')
WRITE (3, REC=1) 'abcdefghijklmno'
WRITE (3) 4,5
WRITE (3, REC=4) 'pq'
CLOSE (3)  END
```

Binary Direct File



Using Asynchronous I/O

For external files, you can specify that I/O should be asynchronous. By doing this, you allow other statements to execute while an I/O statement is executing.

NOTE
In order to execute a program that uses asynchronous I/O on Linux* or macOS* systems, you must explicitly include one of the following compiler command line options when you compile and link your program:

- `-threads`
- `-reentrancy threaded`
- `-openmp`

On Windows* systems, no extra options are needed to execute a program that uses asynchronous I/O.

Using the ASYNCHRONOUS Specifier

Asynchronous I/O is supported for all READ and WRITE operations to external files. However, if you specify asynchronous I/O, you cannot use variable format expressions in formatted I/O operations.

To allow asynchronous I/O for a file, first specify ASYNCHRONOUS='YES' in its OPEN statement, then do the same for each READ or WRITE statement that you want to execute in this manner.

Execution of an asynchronous I/O statement initiates a "pending" I/O operation, which can be terminated in the following ways:

- by an explicit WAIT (initno) statement, which performs a wait operation for the specified pending asynchronous data transfer operation
- by a CLOSE statement for the file
- by a file-positioning statement such as REWIND or BACKSPACE
- by an INQUIRE statement for the file

Use the WAIT statement to ensure that the objects used in the asynchronous data transfer statements are not prematurely deallocated. (This is especially important for local stack objects and allocatable objects which may be deallocated before completion of the pending operation.) If you do not specify the wait operation, the program may terminate with an Access violation error. The following example shows use of the WAIT statement:

```
module mod
   real, allocatable :: X(:)
end module mod
subroutine sbr()
use mod
integer :: Y(500)
   !X and Y initialization
   allocate (X(500))
   call foo1(X, Y)
   !asynchronous writing
   open(1, asynchronous='yes')
   write(1, asynchronous='yes') X, Y
   !some computation
   call foo2()
   !wait operation
   wait(1)
   !X deallocation
   deallocate(X)
   !stack allocated object Y will be deallocated when the routine returns
end subroutine sbr
```

You can use the INQUIRE statement with the keyword of ASYNCHRONOUS (ASYNCHRONOUS=specifier) to determine whether asynchronous I/O is allowed. If it is allowed, a value of YES is returned.

Additionally, you can use the INQUIRE statement with the keyword of PENDING (PENDING= specifier) to determine whether previously pending asynchronous data transfers are complete.

If an ID= specifier appears and the specified data transfer operation is complete, the variable specified by PENDING is assigned the value False and the INQUIRE statement performs a wait operation for the specified data transfer.

If the ID= specifier is omitted and all previously pending data transfer operations for the specified unit are complete, the variable specified by PENDING is assigned the value False and the INQUIRE statement performs wait operations for all previously pending data transfers for the specified unit.

Otherwise, the variable specified by PENDING is assigned the value True and no wait operations are performed. Previously pending data transfers remain pending.

Using the ASYNCHRONOUS Attribute

A data attribute called ASYNCHRONOUS specifies that a variable may be subject to asynchronous input/output. Assigning this attribute to a variable allows certain optimizations to occur.

Mixed Language Programming

Programming with Mixed Languages Overview

Mixed-language programming is the process of building programs in which the source code is written in two or more languages. It allows you to:

- Call existing code that is written in another language
- Use procedures that may be difficult to implement in a particular language

In mixed-language programming, a routine written in one language calls a function, procedure, or subroutine written in another language. For example, a Fortran program may need to call an existing shared library or system procedure written in another language.

Although mixed language programming is possible between Intel® Fortran and other languages, the primary focus of this section is programming using Intel® Fortran and C. Mixed language programming between these languages is relatively straightforward for these reasons:

- Fortran implements functions, subroutines, and procedures in approximately the same way as C.
- Fortran provides many standard features to improve interoperability with C. An entity is considered to be interoperable if equivalent declarations are possible in both languages. Interoperability is provided for variables, derived types, and procedures. For more information, see Standard Fortran and C Interoperability.

Standard Fortran and C Interoperability

The Intel® Fortran Compiler supports the Fortran standardized mechanism for allowing Fortran code to reliably communicate (or *interoperate*) with C code.

This mechanism includes a group of features for C interoperability, enabling mixed-language programming in a more portable manner.

The Fortran standard discusses interoperability in terms of a "companion C processor." Each Fortran implementation is free to choose which C is its companion. Although the standard explicitly specifies a companion C (not C++) processor, you can use C++, as long as you use features that are compatible with C when interoperating with Fortran.

For Intel® Fortran, the supported C companion is the Intel® C++ Compiler or the Microsoft* Visual C++* Compiler on Windows*, and the Intel® C++ Compiler or gcc* on Linux* and macOS*.

The core principle of interoperability is that something should work the same way in Fortran as it does in C. In terms of interoperability, the following applies:

- Fortran provides a way to reference procedures that are defined by the C programming language or procedures that are described by C prototypes, even if they are not actually defined by means of C.
- Conversely, a procedure defined by a Fortran subprogram can be referenced by a function defined by means of C.
- In addition, you can define global variables that are associated with C variables whose names have external linkage.
- You can also declare Fortran variables, data structures and enumerations that correspond to similar declarations in C.

The following sections describe interoperability requirements for types, variables, procedures, and global data.

Example of Fortran Calling C

The following example calls a C function.

C Function Prototype Example

```
int C_Library_Function(void* sendbuf, int sendcount, int *recvcounts);
```

Fortran Module Example

```
module ftn_C_2
   interface
     integer (C_INT) function C_Library_Function &
     (sendbuf, sendcount, recvcounts) &
        BIND(C, name='C_Library_Function')
        use, intrinsic :: ISO_C_BINDING
        implicit none
        type (C_PTR), value :: sendbuf
        integer (C_INT), value :: sendcount
        type (C_PTR), value :: recvcounts
     end function C_Library_Function
   end interface
end module ftn_C_2
```

Fortran Calling Sequence Example

```
use, intrinsic :: ISO_C_BINDING, only: C_INT, C_FLOAT, C_LOC
use ftn_C_2
...
real (C_FLOAT), target :: send(100)
integer (C_INT) :: sendcount
integer (C_INT), ALLOCATABLE, target :: recvcounts(100)
...
ALLOCATE( recvcounts(100) )
...
call C_Library_Function(C_LOC(send), sendcount, &
C_LOC(recvcounts))
...
```

Example of C Calling Fortran

The following example calls a Fortran subroutine called `Simulation`. This subroutine corresponds to the C void function `simulation`.

Fortran Code Example

```
subroutine Simulation(alpha, beta, gamma, delta, arrays) BIND(C)
   use, intrinsic :: ISO_C_BINDING
   implicit none
   integer (C_LONG), value :: alpha
   real (C_DOUBLE), intent(inout) :: beta
   integer (C_LONG), intent(out) :: gamma
   real (C_DOUBLE),dimension(*),intent(in) :: delta
   type, BIND(C) :: pass
      integer (C_INT) :: lenc, lenf
      type (C_PTR) :: c, f
   end type pass
```

Fortran Code Example

```
   type (pass), intent(inout) :: arrays
   real (C_FLOAT), ALLOCATABLE, target, save :: eta(:)
   real (C_FLOAT), pointer :: c_array(:)
   ...
   ! Associate c_array with an array allocated in C
   call C_F_POINTER (arrays%c, c_array, (/arrays%lenc/) )
   ...
   ! Allocate an array and make it available in C
   arrays%lenf = 100
   ALLOCATE (eta(arrays%lenf))
   arrays%f = c_loc(eta)
   ...
end subroutine Simulation
```

C Struct declaration Example

```
struct pass {int lenc, lenf; float *c, *f;};
```

C Function Prototype Example

```
void simulation(long alpha, double *beta, long *gamma, double delta[], struct pass *arrays);
```

C Calling sequence Example

```
simulation(alpha, &beta, &gamma, delta, &arrays);
```

Using Standard Fortran Interoperability Syntax for Existing Fortran Extensions

Before the introduction of the Standard Fortran interoperability features, extensions provided by Intel® Fortran were used to facilitate programming using code written in Fortran and C. The Fortran 2003 standard defined new language features for C interoperability; in many cases, these features can be used instead of existing Intel® Fortran extensions. The following table lists the legacy Intel® Fortran extensions and shows their Standard Fortran equivalents.

NOTE
Existing code using legacy extensions will continue to work; however, if you are writing new code, you should use the standard syntax.

Legacy Extension	Standard Fortran Interoperability Equivalent
ATTRIBUTES ALIAS	Use BIND(C,NAME="alias-name"). The BIND(C) syntax also implies ATTRIBUTES DECORATE; the compiler applies whatever name decoration (leading or trailing underscores) that C

Legacy Extension	Standard Fortran Interoperability Equivalent
	would use for the name. If the NAME= keyword is omitted, Intel® Fortran will use the Fortran name converted to lowercase on all platforms. If the procedure has no arguments, you must indicate that with () when adding BIND. All arguments to a routine specified as "interoperable" (with BIND(C)) must themselves be interoperable. You can also specify BIND(C) on module variables and COMMON blocks.
ATTRIBUTES C	Use BIND(C) (see ALIAS above), which has a similar effect to ATTRIBUTES C except that it does not change the argument passing mechanism to be by-value. Use the Fortran standard VALUE attribute if you need to pass by value. BIND(C) also specifies that small records are passed and returned as function value results the same way C would, which may be different from the Intel® Fortran default. Like ATTRIBUTES C, BIND(C) lowercases the external name and adds any necessary name decoration.
ATTRIBUTES DECORATE	Typically used with ATTRIBUTES ALIAS. See ATTRIBUTES ALIAS above.
ATTRIBUTES DEFAULT	Not needed when using BIND(C); the compiler always uses the semantics of the C compiler regardless of the setting of command-line options such as `iface`.
ATTRIBUTES EXTERN	Use BIND(C) with a module variable.
ATTRIBUTES REFERENCE	Not needed when using BIND(C). Typically used with character arguments, or to override the implicit pass-by-value of ATTRIBUTES C.
ATTRIBUTES STDCALL	No equivalent. The use of STDCALL with BIND(C) is supported in Intel® Fortran and, for Windows* on IA-32 architecture only, it changes the external procedure name and stack conventions. For more information, see ATTRIBUTES C and STDCALL.
ATTRIBUTES VALUE	Use the Fortran-standard VALUE attribute. This has an additional effect when used with a Fortran procedure; the dummy argument is received by value and then copied to a temporary

Legacy Extension	Standard Fortran Interoperability Equivalent
	variable that can be modified within the procedure. Once the procedure exits, the temporary value is discarded.
ATTRIBUTES VARYING	No equivalent.
%LOC function	Use the C_LOC function from intrinsic module ISO_C_BINDING, which may be an appropriate substitute for variables. C_FUNLOC is the corresponding function for procedures.
%VAL function	Declare the argument with the VALUE attribute.
%REF function	No equivalent; this is the default when BIND(C) is used.

Standard Tools for Interoperability

ISO_C_BINDING

The intrinsic module provides a set of named constants and procedures that can assist you in programming with mixed languages.

Using Intrinsic Module Example

```
USE, INTRINSIC::ISO_C_BINDING
```

There are two groups of named constants included in this intrinsic module -- those that hold kind type parameter values for intrinsic types and those that provide a Fortran equivalent to some of the C special characters, including:

Named constant	C definition	Value
C_NULL_CHAR	null character	'\0'
C_ALERT	alert	'\a'
C_BACKSPACE	backspace	'\b'
C_FORMFEED	form feed	'\f'
C_NEW_LINE	new line	'\n'
C_CARRIAGE_RETURN	carriage return	'\r'
C_HORIZONTAL_TAB	horizontal tab	'\t'
C_VERTICAL_TAB	vertical tab	'\v'

The procedures included in ISO_C_BINDING are all generic, not specific. With the exception of C_F_POINTER and C_F_PROCPOINTER, all of the procedures are pure. They include:

- C_ASSOCIATED
- C_F_POINTER
- C_F_PROCPOINTER
- C_FUNLOC
- C_LOC

- C_SIZEOF

Additionally, ISO_C_BINDING includes the following derived types to interoperate with C pointers:

- C_PTR
- C_FUNPTR
- C_NULL_PTR
- C_NULL_FUNPTR

BIND(C)

Fortran 2003 introduced the *language-binding-spec* attribute, using the keyword BIND. The syntax is:

BIND(C [, NAME=*scalar-default-char-constant-expr*])

C is the only language name you can specify. Generally, an entity with the BIND(C) attribute behaves as if it were the corresponding entity in the companion C processor.

The optional NAME= specifier allows you to use a different external name than the one the standard prescribes, which is what the companion C processor would do with the Fortran name forced to lowercase. If the C name was mixed-case, specify the mixed-case name here without any name decoration, such as leading underscores. The compiler applies whatever decoration the C processor would with the same name. So NAME= is not a strict replacement for the ALIAS attribute extension, it is more like ALIAS combined with DECORATE.

BIND(C) is not equivalent to ATTRIBUTES C. Although these both downcase the external name, BIND(C) does not imply pass-by-value and has other effects that are different from ATTRIBUTES C.

You can specify ATTRIBUTES STDCALL for an interoperable procedure (a procedure whose declaration includes the BIND(C) language binding attribute). This combination has the following effects for Windows* applications targeting IA-32 architecture:

- The calling mechanism is changed to STDCALL, which affects how the stack is cleaned up on procedure exit.
- The external name from the BIND attribute is suffixed with `@n`, where n is the number of bytes to be removed from the stack on return.

No other effects from STDCALL, such as pass-by-value, are provided. The Fortran standard VALUE attribute (not ATTRIBUTES VALUE) may be used if desired. For all other platforms, specifying STDCALL with BIND(C) has no effect. For more information, see ATTRIBUTES C and STDCALL.

BIND(C) on procedures

BIND(C) is often used on procedures. It can be specified in INTERFACE blocks to specify the interface of an external interoperable procedure, and on any Fortran procedures that you want to make interoperable. For SUBROUTINEs and FUNCTIONs, you need to specify BIND(C) after the argument list. For functions, you can specify BIND(C) before or after the RESULT clause. For example:

```
SUBROUTINE INTEROP_SUB (ARG) BIND(C,NAME="InteropSub")

FUNCTION INTEROP_FUN (ARG) BIND(C,NAME="InteropFun") RESULT (IAMFUN)
```

The above includes an external name, which is not required. You can also specify BIND(C) in a PROCEDURE declaration, in which case it appears in the normal list of attributes before the :: separator.

Specifying BIND(C) for procedures results in the following:

- The external name is what the C compiler would use, with the Fortran name lowercased (unless NAME= is specified).
- Arguments are passed and received by reference (unless the VALUE attribute is specified for the argument).
- Only interoperable arguments are allowed.
- No hidden arguments are allowed.
- Function type must be interoperable and function values are returned exactly as the C compiler would (this mainly affects small derived types).

The standard allows for passing character strings to interoperable procedures. You can pass a character argument of default kind (kind C_CHAR is the default in Intel® Fortran); the corresponding dummy argument is an explicit-shape array of single characters. Because no length is passed, you will need to provide the length another way (usually by appending a NUL character on the end.)

The standard does not provide an easy way to write a Fortran interoperable routine that accepts a string from C. You must declare the dummy argument as an array of single characters. You can use the combination of the C_LOC and C_F_POINTER procedures, both defined in intrinsic module ISO_C_BINDING, to "cast" a character array argument to a Fortran pointer to a character string. An example follows:

```
subroutine Interop_sub(arg) BIND(C)
USE, INTRINSIC :: ISO_C_BINDING
CHARACTER, DIMENSION(*) :: ARG
CHARACTER(1000), POINTER :: LCL_ARG ! Local pointer to argument
CALL C_F_POINTER(C_LOC(ARG), LCL_ARG)
```

In the above, `ARG` comes in as an assumed-size array of single characters, with no length. The C_F_POINTER subroutine converts a C pointer to a Fortran pointer. C_LOC is used to get a C pointer (of type C_PTR) of the argument and convert it to the Fortran pointer `LCL_ARG`. The result is that you can use `LCL_ARG` as a character string.

In the example, `LCL_ARG` has an explicit length. There is no way to make this pointer the correct length of the incoming string. Use INDEX to find the location of the NUL character, or some other method, to obtain the length and then use that in subsequent references.

BIND

Interoperating with arguments using C descriptors

These are facilities for interoperable procedure interfaces that specify dummy arguments that are assumed-shape arrays, have assumed character length, or have the ALLOCATABLE, POINTER, or OPTIONAL attributes.

Assumed-rank

An assumed-rank object is a dummy variable whose rank is assumed from its actual argument. This facilitates interoperability with C functions that can accept arguments of arbitrary rank. The intrinsic function, RANK, can be used to obtain the rank of an assumed-rank variable.

A procedure must have an explicit interface if it has a dummy argument that is assumed-rank.

The SHAPE, SIZE, and UBOUND intrinsic functions are defined for an assumed-rank array that is associated with an assumed-size array.

An assumed-rank dummy argument may correspond to an actual argument of any rank. If the actual argument has rank zero, the dummy argument has rank zero; the shape is a zero-sized array and the LBOUND and UBOUND intrinsic functions, with no DIM argument, return zero-sized arrays. If the actual argument has rank greater than zero, the rank and extents of the dummy argument are assumed from the actual argument, including no final extent for an assumed-size array. If the actual argument is an array and the dummy argument has the ALLOCATABLE or POINTER attribute, the bounds of the dummy argument are assumed from the actual argument.

Assumed-type

An assumed-type object is a dummy variable declared as `TYPE(*)`. This simplifies interoperability with C formal parameters of type `(void *)`.

An explicit interface is required for a procedure that has a dummy argument that is assumed-type because an assumed-type dummy argument is polymorphic.

An assumed-type dummy argument must not correspond to an actual argument that is of derived type with type parameters, type-bound procedures, or final subroutines.

CFI_cdesc

A C descriptor is a C structure of type `CFI_cdesc` that is defined in the file `ISO_Fortran_binding.h`.

Restrictions for BIND(C)

If BIND(C) is specified for a procedure, each dummy argument must be an interoperable procedure or a variable that is interoperable, assumed shape, assumed rank, assumed type, of assumed character length, or has the ALLOCATABLE or POINTER attribute. If BIND(C)is specified for a function, the function result must be an interoperable scalar variable.

A dummy argument of a procedure that is BIND(C) must not have both the OPTIONAL and VALUE attributes.

A variable that is a dummy argument of a procedure that is BIND(C) must be of interoperable type or assumed type.

A coarray shall not be a dummy argument of a BIND(C) procedure.

The ALLOCATABLE or POINTER attribute must not be specified for a default-initialized dummy argument of a BIND(C) procedure.

Further Requirements

Variables with the ASYNCHRONOUS attribute can be used for asynchronous communications between Fortran and C procedures.

When a Fortran procedure that has an INTENT (OUT) allocatable dummy argument is invoked by a C function, and the actual argument in the C function is the address of a C descriptor that describes an allocated allocatable variable, the variable is deallocated on entry to the Fortran procedure. When a C function is invoked from a Fortran procedure via an interface with an INTENT (OUT) allocatable dummy argument, and the actual argument in the reference to the C function is an allocated allocatable variable, the variable is deallocated on invocation (before execution of the C function begins).

ISO_Fortran_binding.h

The types, macros, and functions declared in `ISO_Fortran_binding.h` can be used by a C function to interpret C descriptors and allocate and deallocate objects represented by C descriptors. These provide a means to specify a C prototype that interoperates with a Fortran interface that has an allocatable, assumed character length, assumed-rank, assumed-shape, or data pointer dummy argument.

The `ISO_Fortran_binding.h` is a C header file that contains these definitions:

- The C structures `CFI_cdesc_t` and `CFI_dim_t`
- The typedef definitions for `CFI_attribute_t`, `CFI_index_t`, `CFI_rank_t`, and `CFI_type_t`
- The macro `CFI_CDESC_T` and macro definitions that expand to integer constants with various useful values
- The C function prototypes or macro definitions for `CFI_address`, `CFI_allocate`, `CFI_deallocate`, `CFI_establish`, `CFI_is_contiguous`, `CFI_section`, `CFI_select_part`, and `CFI_setpointer`. Some of these functions return an error indicator; this is an integer value that indicates whether an error condition was detected. The value zero `CFI_SUCCESS` indicates that no error condition was detected, and a nonzero value indicates which error condition was detected. The "Macros and typedefs in ISO_Fortran_binding.h" section lists the standard error conditions and the macro names for their corresponding error codes.

  In function arguments representing subscripts, bounds, extents, or strides, the ordering of the elements is the same as the ordering of the elements of the `dim` member of a C descriptor.

Restrictions on C functions interoperating with Fortran procedures

Any C function inter-operating with Fortran procedures must meet these restrictions:

- A C descriptor shall not be initialized, updated, or copied other than by calling the functions in `ISO_Fortran_binding.h`.
- If the address of a C descriptor is a formal parameter that corresponds to a Fortran actual argument or is a C actual argument that corresponds to a Fortran dummy argument,
  - the C descriptor shall not be modified if either the corresponding dummy argument in the Fortran interface has the INTENT(IN) attribute or the C descriptor is for a nonallocatable nonpointer object, and
  - the `base_addr` member of the C descriptor shall not be accessed before it is given a value if the corresponding dummy argument in the Fortran interface has the POINTER and INTENT(OUT) attributes.

  In this context, modification refers to any change to the location or contents of the C descriptor, including establishing and updating. The intent of these restrictions is that the C descriptors will remain intact at all times that they are accessible to an active Fortran procedure, so that the Fortran code is not required to copy them.
- Within a C function, an allocatable object shall be allocated or deallocated only by execution of the `CFI_allocate` and `CFI_deallocate` functions. A Fortran pointer can become associated with a target by execution of the CFI allocate function.
- Calling `CFI_allocate` or `CFI_deallocate` for a C descriptor changes the allocation status of the Fortran variable it describes and causes the allocation status of any associated allocatable variable to change accordingly.
- If the address of an object is the value of a formal parameter that corresponds to a nonpointer dummy argument in a BIND(C) interface, then
  - if the dummy argument has the INTENT (IN) attribute, the object must not be defined or become undefined, and
  - if the dummy argument has the INTENT (OUT) attribute, the object must not be referenced before it is defined.
- When a Fortran object is deallocated, or execution of its host function is completed, or its association status becomes undefined, all C descriptors and C pointers to any part of it become undefined, and any further use of them is undefined behavior.
- A C descriptor whose address is a formal parameter that corresponds to a Fortran dummy argument becomes undefined on return from a call to the function from Fortran. If the dummy argument does not have either the TARGET or ASYNCHRONOUS attribute, all C pointers to any part of the object described by the C descriptor become undefined on return from the call, and any further use of them is undefined behavior.
- When a Fortran object is deallocated, or execution of its host function is completed, or its association status becomes undefined, all C descriptors and C pointers to any part of it become undefined, and any further use of them is undefined behavior.
- If the address of a C descriptor is passed as an actual argument to a Fortran procedure, the C lifetime of the C descriptor shall not end before the return from the procedure call.
- If an object is passed to a Fortran procedure as a nonallocatable, nonpointer dummy argument, its lifetime shall not end before the return from the procedure call.
- If the lifetime of a C descriptor for an allocatable object that was established by C ends before the program exits, the object shall be unallocated at that time.
- If a Fortran pointer becomes associated with a C object, the association status of the Fortran pointer becomes undefined when the lifetime of the C object ends.

C Structures, Typedefs, and Macros for Interoperability

C Structures, Typedefs, and Macros for Interoperability

The C structures CFI_dim_t and CFI_cdesc_t

CFI_dim_t is a typedef name for a C structure. It is used to represent lower bound, extent, and memory stride information for one dimension of an array. CFI_dim_t contains at least the following members in any order:

- CFI_index_t lower_bound – The value of the lower bound for the dimension being described.
- CFI_index_t extent – The value is the number of elements in the dimension being described or -1 for the last dimension of an assumed-size array.
- CFI_index_t sm – The value is the memory stride for a dimension; this is the difference in bytes between the addresses of successive elements in the dimension being described.

CFI_cdesc_t is a typedef name for a C structure, which contains a flexible array member. The first three members of the structure are base_addr, elem_len, and version in that order. The final member is dim. All other members must be between version and dim, in any order.

- void * base_addr – If the object Interoperating with arguments using C descriptors is an unallocated allocatable variable or a pointer that is disassociated, the value is a null pointer. If the object has zero size, the value is not a null pointer but is processor-11 dependent. Otherwise, the value is the base address of the object being described. The base address of a scalar is its C address. The base address of an array is the C address of the first element in Fortran array element order.
- size_t elem_len – If the object is a scalar, the value is the storage size in bytes of the object; otherwise, the value is the storage size in bytes of an element of the object.
- int version – The value is the value of CFI_VERSION in the source file ISO_Fortran_binding.h that defined the format and meaning of this C descriptor when the descriptor was established.
- CFI_rank_t rank – The value is the number of dimensions of the Fortran object being described; if the object is a scalar, the value is zero.
- CFI_type_t type – The value is the specifier for the type of the object. Each interoperable intrinsic C type has a specifier. Specifiers are also provided to indicate that the type of the object is an interoperable structure, or is unknown. The macros listed in the table below provide values that correspond to each type code specifier.

Macros for Type Codes

Macro name	C Type
CFI_type_signed_char	signed char
CFI_type_short	short int
CFI_type_int	int
CFI_type_long	long int
CFI_type_long_long	long long int
CFI_type_size_t	size_t
CFI_type_int8_t	int8_t
CFI_type_int16_t	int16_t
CFI_type_int32_t	int32_t
CFI_type_int64_t	int64_t
CFI_type_int_least8_t	int_least8_t
CFI_type_int_least16_t	int_least16_t
CFI_type_int_least32_t	int_least32_t
CFI_type_int_least64_t	int_least64_t
CFI_type_int_fast8_t	int_fast8_t

Macro name	C Type
CFI_type_int_fast16_t	int_fast16_t
CFI_type_int_fast32_t	int_fast32_t
CFI_type_int_fast64_t	int_fast64_t
CFI_type_intmax_t	intmax_t
CFI_type_intptr_t	intptr_t
CFI_type_ptrdiff_t	ptrdiff_t
CFI_type_float	float
CFI_type_double	double
CFI_type_long_double	long double
CFI_type_float_Complex	float _Complex
CFI_type_double_Complex	double _Complex
CFI_type_long_double_Complex	long double _Complex
CFI_type_Bool	_Bool
CFI_type_char	char
CFI_type_cptr	void *
CFI_type_struct	interoperable C structure
CFI_type_other	not otherwise specified

  - The value for `CFI_type_other` is negative and distinct from all other type specifiers.
  - `CFI_type_struct` specifies a C structure that is interoperable with a Fortran derived type; its value is positive and distinct from all other type specifiers.
  - If a C type is not interoperable with a Fortran type and kind supported by the Fortran processor, its macro evaluates to a negative value.
  - Otherwise, the value for an intrinsic type is positive.
- `CFI_attribute_t attribute` – The value is the value of an attribute code that indicates whether the object described is allocatable, a data pointer, or a nonallocatable, nonpointer data object. The values are nonnegative and distinct.

  The macros listed in the table below provide values that correspond to each attribute code.

  Macros for Attribute Codes

Macro	Attribute code indicated
`CFI_attribute_pointer`	data pointer object
`CFI_attribute_allocatable`	allocatable object
`CFI_attribute_other`	nonallocatable, nonpointer object

  - `CFI_attribute_pointer` specifies a data object with the Fortran POINTER attribute.
  - `CFI_attribute_allocatable` specifies an object with the Fortran ALLOCATABLE attribute.
  - `CFI_attribute_other` specifies a nonallocatable nonpointer object.
- `CFI_dim_t dim` – The number of elements in the dim array is equal to the rank of the object. Each element of the array contains the lower bound, extent, and memory stride information for the corresponding dimension of the Fortran object.

For a C descriptor of an array pointer or allocatable array, the value of the lower_bound member of each element of the dim member of the descriptor is determined by argument association, allocation, or pointer association. For a C descriptor of a nonallocatable nonpointer object, the value of the lower_bound member of each element of the dim member of the descriptor is zero.

In a C descriptor of an assumed-size array, the extent member of the last element of the dim member has the value -1. The value of elem_len for a Fortran CHARACTER object is equal to the character length times the number of bytes of a single character of that kind. If the kind is C_CHAR, this value will be equal to the character length.

Macros and typedefs in ISO_Fortran_binding.h

Except for CFI_CDESC_T, each macro defined in ISO_Fortran_binding.h expands to an integer constant expression that is either a single token or a parenthesized expression that is suitable for use in #if preprocessing directives.

CFI_CDESC_T is a function-like macro that takes one argument, which is the rank of the C descriptor to create, and evaluates to an unqualified type of suitable size and alignment for defining a variable to use as a C descriptor of that rank. The argument shall be an integer constant expression with a value that is greater than or equal to zero and less than or equal to CFI_MAX_RANK. A pointer to a variable declared using CFI_CDESC_T can be cast to CFI_cdesc_t *. A variable declared using CFI_CDESC_T must not have an initializer.

The CFI_CDESC_T macro provides the memory for a C descriptor. The address of an entity declared using the macro is not usable as an actual argument corresponding to a formal parameter of type CFI_cdesc_t * without an explicit cast.

CFI_index_t is a typedef name for a standard signed integer type capable of representing the result of subtracting two pointers.

The CFI_MAX_RANK macro has a value equal to the largest rank supported, i.e., 31. CFI_rank_t is a typedef name for a standard integer type capable of representing the largest supported rank.

The CFI_VERSION macro has a processor-dependent value that encodes the version of the ISO_Fortran_binding.h source file containing this macro. This value is increased if a new version of the source file is incompatible with the previous version.

CFI_attribute_t is a typedef name for a standard integer type capable of representing the values of the attribute codes.

CFI_type_t is a typedef name for a standard integer type capable of representing the values for the supported type specifiers.

The macros in the table below are for use as error codes. The macro CFI_SUCCESS is the integer constant 0. The value of each macro other than CFI_SUCCESS is nonzero and is different from the values of the other error code macros.

Macros for Error Codes

Macro name	Error condition
CFI_SUCCESS	No error detected.
CFI_ERROR_BASE_ADDR_NULL	The base address member of a C descriptor is a null pointer in a context that requires a non-null pointer value.
CFI_ERROR_BASE_ADDR_NOT_NULL	The base address member of a C descriptor is not a null pointer in a context that requires a null pointer value.
CFI_INVALID_ELEM_LEN	The value supplied for the element length member of a C descriptor is not valid.
CFI_INVALID_RANK	The value supplied for the rank member of a C descriptor is not valid.
CFI_INVALID_TYPE	The value supplied for the type member of a C descriptor is not valid.
CFI_INVALID_ATTRIBUTE	The value supplied for the attribute member of a C descriptor is not valid.

Macro name	Error condition
CFI_INVALID_EXTENT	The value supplied for the extent member of a CFI_dim_t structure is not valid.
CFI_INVALID_DESCRIPTOR	A C descriptor is invalid in some way.
CFI_ERROR_MEM_ALLOCATION	Memory allocation failed.
CFI_ERROR_OUT_OF_BOUNDS	A reference is out of bounds.

Interoperating with arguments using C descriptors

Data Types

Fortran and C support many of the same data types, but there are no direct correlations.

One difference is that Fortran has the concept of kinds. C treats these kinds as distinct types. For example, the Fortran INTEGER. C has integer types that range from `short int` to `long long int`, and has specialty types such as `intptr_t`. Fortran may not have a corresponding kind. For each interoperable C `integer` type, the ISO_C_BINDING declares a named constant (PARAMETER) that gives the kind number for the implementation's equivalent INTEGER kind.

Consider the simple C `int` type. This corresponds to INTEGER(C_INT), where C_INT is defined in the ISO_C_BINDING. In Intel® Fortran, the value is always four, as a C `int` corresponds with Fortran INTEGER(4). Other Fortran implementations may use different kind numbers. Using the named constant ensures portability.

Now consider the C `intptr_t` type. This integer is large enough to hold a pointer (address). In Intel® Fortran, this corresponds to INTEGER(C_INTPTR_T). It is INTEGER(4) when building a 32-bit application, and INTEGER(8) when building a 64-bit application.

Fortran has no unsigned integer types, so there are no constants for C unsigned types. These types are *not* interoperable.

If there is a kind of C type that is not supported by the Fortran implementation, the named constant for that type is defined as -1 and generates a compile-time error if used.

There are constants defined for REAL, COMPLEX, LOGICAL, and CHARACTER. For REAL, the standard offers the possibility of a C `long double` type. This is implemented in different ways by various C compilers on various platforms supported by Intel® Fortran.

- **gcc* on 32-bit Linux*:** The `long double` is an 80-bit floating type, as supported by the X87 instruction set. It is not supported by Intel® Fortran, so the C_LONG_DOUBLE is -1.
- **gcc on macOS*:** The C_LONG_DOUBLE is defined as 16.
- **Windows*:** The `long double` is treated the same as a `double`, so the C_LONG_DOUBLE is defined as 8.
- **64-bit Linux*:** The C_LONG_DOUBLE is defined as 16.

NOTE Use the constants for kind values and the corresponding types in C to ensure matching.

NOTE In Intel® C/C++ on Linux*, a `long double` can be forced to be a 128-bit IEEE format floating-point data type using the `-mlong-double-128` command line option. On all platforms, Intel® C/C++ supports `__float128` in the source code. On Windows*, Intel® C/C++ supports the `_Quad` type in the source code by using the command line option, `/Qoption,cpp,--extended_float_types`.

LOGICAL and CHARACTER need special treatment for interoperability. The Fortran standard states that LOGICAL corresponds to the (ISO_C_BINDING) C `_Bool` type, and defines a single kind value of C_BOOL, which is 1 in Intel® Fortran. By default, Intel® Fortran, tests LOGICALs for true/false differently than C does. Where C uses zero for false and not-zero for true, Intel® Fortran defaults to using -1 (all bits set) as true and

zero as false. If you are going to use LOGICAL types to interoperate with C, specify the option `fpscomp[:]logicals` to change the interpretation to be C-like. This is included when using the option `standard-semantics`, which is recommended for using Fortran 2003 (or later) features. C does not have character strings. It has arrays of single characters, and this is how strings in Fortran must be represented. There is a kind value defined as C_CHAR, which corresponds to the C `char` type. Only character variables with a length of one are interoperable. See Procedures for more information.

Derived types can also be interoperable. For additional information and restrictions, see Derived Types.

Procedures
Derived Types

Scalar Types

The commonly used types are included in the following table. The following applies:

- Integer types in Fortran are always signed. In C, integer types may be specified as signed or unsigned, but are signed by default.
- The values of C_LONG, C_SIZE_T, C_LONG_DOUBLE, and C_LONG_DOUBLE_COMPLEX are different on different platforms.

Named constant from ISO_C_BINDING (kind type parameter if value is positive)	C type	Equivalent Fortran type
C_SHORT	short int	INTEGER(KIND=2)
C_INT	int	INTEGER(KIND=4)
C_LONG	long int	INTEGER (KIND=4 or 8)
C_LONG_LONG	long long int	INTEGER(KIND=8)
C_SIGNED_CHAR	signed char unsigned char	INTEGER(KIND=1)
C_SIZE_T	size_t	INTEGER(KIND=4 or 8)
C_INT8_T	int8_t	INTEGER(KIND=1)
C_INT16_T	int16_t	INTEGER(KIND=2)
C_INT32_T	int32_t	INTEGER(KIND=4)
C_INT64_T	int64_t	INTEGER(KIND=8)
C_FLOAT	float	REAL(KIND=4)
C_DOUBLE	double	REAL(KIND=8)
C_LONG_DOUBLE	long double	REAL(KIND=8 or 16)
C_FLOAT_COMPLEX	float _Complex	COMPLEX(KIND=4)
C_DOUBLE_COMPLEX	double _Complex	COMPLEX(KIND=8)
C_LONG_DOUBLE_COMPLEX	long double _Complex	COMPLEX(KIND=8 or 16)
C_BOOL	_Bool	LOGICAL(KIND=1)
C_CHAR	char	CHARACTER(LEN=1)

While there are named constants for all possible C types, every type is not necessarily supported on every processor. Lack of support is indicated by a negative value for the constant in the module.

For a character type to be interoperable, you must either omit the length type parameter or specify it using a constant expression whose value is one.

Characters

The C language does not have character strings. Instead, it has arrays of single characters, so this is how you must represent a character string in Fortran.

There is a kind value defined, C_CHAR, corresponding to the C `char` type. However, only character variables with a length of one (1) are interoperable.

The following shows a Fortran program passing a string to a C routine and the C routine calling a Fortran routine with a new string.

Fortran Program Example

```
program demo_character_interop
    use, intrinsic :: iso_c_binding
    implicit none

    interface
    subroutine c_append (string) bind(C)
    character(len=1), dimension(*), intent(in) :: string
    end subroutine c_append
    end interface

    ! Call C routine passing an ordinary character value
    ! The language allows this to match an array of
    ! single characters of default kind
    call c_append('Intel Fortran'//C_NULL_CHAR)
end program demo_character_interop

subroutine fort_print (string) bind(C)
    use, intrinsic :: iso_c_binding
    implicit none

    ! Must declare argument as an array of single characters
    ! in order to be "interoperable"
    character(len=1), dimension(100), intent(in) :: string
    integer s_len ! Length of string
    character(100), pointer :: string1
    character(100) :: string2

    ! One way to convert the array to a character variable
    call C_F_POINTER(C_LOC(string),string1)
    s_len = INDEX(string1,C_NULL_CHAR) - 1
    print *, string1(1:s_len)

    ! Another way to convert
    string2 = TRANSFER(string,string2) ! May move garbage if source length < 100
    s_len = INDEX(string2,C_NULL_CHAR) - 1
    print *, string2(1:s_len)

    end subroutine fort_print
```

C Routine Example

```
C module (c_append.c):
#include <string.h>
extern void fort_print(char * string); /* Fortran routine */
void c_append (char * string) {
    char mystring[100];
    strcpy(mystring, string);
    strcat(mystring, " interoperates with C");
    /* Call Fortran routine passing new string */
    fort_print (mystring);
    return;
}
```

Pointers

For interoperating with C pointers, the module ISO_C_BINDING contains the derived types C_PTR and C_FUNPTR, which are interoperable with C object and function type pointers, respectively.

These types, as well as certain procedures in the module, provide the mechanism for passing dynamic arrays between the two languages. Because its elements do not need to be contiguous in memory, a Fortran pointer target or assumed-shape array cannot be passed to C. However, you can pass an allocated allocatable array to C, and you can associate an array allocated in C with a Fortran pointer. Additionally, as shown in the following, you can convert a pointer in C format to one in Fortran format.

Fortran Program Example

```
program demo_c_f_pointer
       use, intrinsic :: iso_c_binding
       implicit none

       interface
         function make_array(n_elements) bind(C)
           import ! Make iso_c_binding visible here
           type(C_PTR) :: make_array
           integer(C_INT), value, intent(IN) :: n_elements
         end function make_array
       end interface

       type(C_PTR) :: cptr_to_array
       integer(C_INT), pointer :: array(:) => NULL()
       integer, parameter :: n_elements = 3 ! Number of elements

       ! Call C function to create and populate an array
       cptr_to_array = make_array(n_elements)
       ! Convert to Fortran pointer to array of n_elements elements
       call C_F_POINTER (cptr_to_array, array, [n_elements])
       ! Print value
       print *, array

end program demo_c_f_pointer
```

C Module Example

```
#include <stdlib.h>
int  *make_array(int n_elements) {
          int *parray;
```

C Module Example

```
          int i;
   parray = (int*) malloc(n_elements * sizeof(int));
   for (i = 0; i < n_elements; i++) {
       parray[i] = i+1;
   }
   return parray;
}
```

Derived Types

For a derived type to be interoperable with C, you must specify the BIND attribute, as shown in the following:

Specifying BIND Example

```
type, BIND(C) :: MyType
```

Additionally, as shown in the examples that follow, each component must have an interoperable type and interoperable type parameters, must not be a pointer, and must not be allocatable. This allows Fortran and C types to correspond.

Interoperable Type and Type Parameter Example

```
typedef struct {
  int m, n;
  float r;
} MyCtype
```

The above is interoperable with the following:

```
use, intrinsic :: ISO_C_BINDING
type, BIND(C) :: MyFtype
integer(C_INT) :: i, j
real(C_FLOAT) :: s
end type MyFtype
```

The following restrictions apply to a derived type specified with the BIND attribute:

- It cannot have the SEQUENCE attribute
- It cannot be an extended type
- It cannot have type-bound procedures

Variables

A scalar Fortran variable is interoperable if its type and type parameters are interoperable and it is not a pointer.

An array Fortran variable is interoperable if its type and type parameters are interoperable and it has an explicit shape or assumed size. It interoperates with a C array of the same type, type parameters, and shape, but with subscripts reversed.

For example, a Fortran array declared as `integer :: a(18, 3:7, *)` is interoperable with a C array declared as `int b[][5][18]`.

Scalar variables are interoperable only if their type parameters (kind and length) are interoperable (see above), they are not a coarray, do not have the POINTER or ALLOCATABLE attribute, and if character length is not assumed nor defined by a non-constant expression.

Arrays are interoperable if the base type meets the scalar variable requirements above, if they are explicit shape or assumed-size, and are not zero-sized. Furthermore, assumed-size arrays are interoperable only with C arrays that have no size specified. An allocatable array, coarray, or array pointer is not interoperable.

Global Data

Global Data Overview

A module variable or a common block can interoperate with a C global variable if the Fortran entity uses the BIND attribute and the members of that entity are also interoperable. For example, consider the entities `c_extern`, `c2`, `com` and `single` in the following module:

Interoperability Example

```
module LINK_TO_C_VARS
   use, intrinsic :: ISO_C_BINDING
   integer(C_INT), BIND(C) :: c_extern
   integer(C_LONG) :: c2
   BIND(C, name='myVariable') :: c2
   common /com/ r,s
   real(C_FLOAT) :: r,s,t
   BIND(C) :: /com/, /single/
   common /single/ t
end module LINK_TO_C_VARS
```

These can interoperate with the following C external variables

```
int c_extern;
long myVariable;
struct {float r, s;} com;
float single;
```

Accessing Global Parameters Example

```
    MODULE Examp
      integer, BIND(C)::idata(20)
      real::rdata(10)
    END MODULE
```

In Fortran, a variable can access a global parameter by using the standard BIND C attribute.

In the above, two external variables are created (the latter with proper case and decoration): *idata* and *foo_mp_rdata*.

Use the BIND attribute to resolve name discrepancies with C.

Global Variable Statement Example

```
  int idata[20]; // declared as global (outside of any function)
```

Fortran can declare the variable global (COMMON) and other languages can reference it as external

```
 ! Fortran declaring PI global
  real pi_r
  COMMON /pi/ pi_r ! Common Block and variable names
  BIND(C)::/pi/
```

Use of BIND(C) above means that the name will be appropriately decorated for the target and made lowercase.

In C, the variable is referenced as an external with the statement

```
//C code with external reference to pi
extern float pi;
```

Note that the global name C references is the name of the Fortran common block (`pi`), not the name of a variable within a common block (`pi_r`). Therefore, you cannot use blank common (unnamed) to make data accessible between C and Fortran.

See Also

BIND C **Statement and Attribute:** Specifies that an object is interoperable with C and has external linkage.

COMMON

To reference C structures from Fortran common blocks and vice versa, you must take into account how common blocks and structures differ in their methods of storing member variables in memory. Fortran places common block variables into memory in order as close together as possible, with the following rules:

- A single BYTE, INTEGER(1), LOGICAL(1), or CHARACTER variable in common block list begins immediately following the previous variable or array in memory.
- All other types of single variables begin at the next even address immediately following the previous variable or array in memory.
- All arrays of variables begin on the next even address immediately following the previous variable or array in memory, except for CHARACTER arrays which always follow immediately after the previous variable or array.
- All common blocks begin on a four-byte aligned address.

Because of these rules, you must consider the alignment of C structure elements with Fortran common block elements. Specifically, you should ensure interoperability either by making all variables exactly equivalent types and kinds in both languages (using only 4-byte and 8-byte data types in both languages simplifies this) or by using the C pack pragmas in the C code around the C structure. This makes C data packing compatible with Fortran data packing.

As an example, suppose your Fortran code has a common block named `Really`, as shown:

Fortran Code Example

```
USE, INTRINSIC::ISO_C_BINDING
  REAL (C_float)::x,y,z(6)
  REAL (C_double)::ydbl
  COMMON, BIND(C) / Really /x, y, z(6), ydbl
```

You can access this data structure from your C code with the following external data structures.

C Code Example

```
#pragma pack(2)
extern struct {
 float x, y, z[6];
 double ydbl;
} Really;
#pragma pack()
```

To restore the original packing, you must add `#pragma pack()` at the end of the C structure.

You can also access C structures from Fortran by creating common blocks that correspond to those structures. This is the reverse case from that shown above. However, the implementation is the same; after common blocks and structures have been defined and given a common address (name), and, assuming the alignment in memory has been accounted for, both languages share the same memory locations for the variables.

Once you have accounted for alignment and padding, you can give C access to an entire common block or set of common blocks. Alternatively, you can pass individual members of a Fortran common block in an argument list, just as you can any other data item.

Procedures

For a Fortran procedure to be interoperable with C, it must have an explicit interface and be declared with the `BIND` attribute, as shown in the following:

BIND Interface Example

```
function Func(i, j, k, l, m) BIND(C)
```

In the case of a function, the result must be scalar and interoperable.

A procedure has an associated binding label, which is global in scope. This label is the name recognized by the C processor and is, by default, the lower-case version of the Fortran name (plus any needed leading or trailing underscores). For example, the above function has the binding label `func`. You can specify an alternative binding label as follows:

Alternate Binding Label Example

```
function Func(i, j, k, l, m) BIND(C, name='myC_Func')
```

All dummy arguments must be interoperable. Furthermore, you must ensure that either the Fortran routine uses the `VALUE` attribute for scalar dummy arguments, or that the C routine receives these scalar arguments as pointers to the scalar values. Consider the following call to this C function:

Call to C Function Example

```
int c_func(int x, int *y);
```

As shown here, the interface for the Fortran call to `c_func` must have `x` passed with the `VALUE` attribute. `y` should not have the `VALUE` attribute, since it is received as a pointer:

Fortran Call Example

```
interface
   integer (C_INT) function C_Func(x, y) BIND(C)
     use, intrinsic :: ISO_C_BINDING
     implicit none
     integer (C_INT), value :: x
     integer (C_INT) :: y
   end function C_Func
end interface
```

Alternatively, the declaration for `y` can be specified as a `C_PTR` passed by value:

Passing Pointer by Value Example

```
type (C_PTR), value :: y
```

Platform Specifics

Summary of Mixed-Language Issues

There are important differences in Fortran and C/C++ mixed-language programming; for instance, argument passing, naming conventions, and other interface issues must be thoughtfully and consistently reconciled between any two languages to prevent program failure and indeterminate results. However, the advantages of mixed-language programming often make the extra effort worthwhile.

A summary of major Fortran and C/C++ mixed-language issues follows:

- Generally, Fortran/C programs are mixed to allow one language to use existing code written in the other. Either Fortran or C can call the other, so the main routine can be in either language. On Linux* and macOS* systems, if Fortran is not the main routine, the `-nofor-main` compiler option must be specified on the `ifort` command line that links the application.
- When the main program is written in Fortran, the Fortran compiler automatically creates any code needed to initialize the Fortran Run-time Library (RTL). The RTL provides the Fortran environment for input/output and exception handling. When the main program is written in C/C++, the C main program needs to call for_rtl_init_ to initialize the Fortran RTL and for_rtl_finish_ at the end of the C main program to shut down the Fortran RTL gracefully. With the Fortran RTL initialized, Fortran I/O and error handling will work correctly even when C/C++ routines are called.
- For mixed-language applications, the Intel® Fortran main program can call subprograms written in C/C++ if the appropriate calling conventions are used.

  To use the same Microsoft* visual development environment for multiple languages, you must have the same version of the visual development environment for your languages.
- On Linux* and macOS* systems, Fortran adds an underscore to the end of external names; C does not.
- Fortran changes the case of external names to lowercase on Linux* and macOS* and to uppercase on Windows*; C leaves them in their original case.
- By default, Fortran passes data by reference; C by value. In both languages, the other method can be specified.

  NOTE
  It is possible to override some default Fortran behavior by using BIND(C) specifier. This is the preferred method. You can also override default Fortran behavior by using ATTRIBUTES and ALIAS.

- Fortran subroutines are equivalent to C void routines.
- Fortran requires that the length of strings be passed; C is able to calculate the length based on the presence of a trailing null. Therefore, if Fortran is passing a string to a C routine, that string needs to be terminated by a null; for example:

```
"mystring"c or  StringVar // CHAR(0)
```

- For COMPLEX, REAL*16, CHARACTER, derived types and ALLOCATABLE or array data types, Fortran adds a hidden first argument to contain function return values.
- On Linux*, the `-fexceptions` option enables C++ exception handling table generation, preventing Fortran routines in mixed-language applications from interfering with exception handling between C++ routines.
- For more information on debugging mixed language programs on Windows*, see Debugging Mixed-Language Programs.

Calling Subprograms from the Main Program (Windows*)

In mixed-language applications, an Intel® Visual Fortran main program can call subprograms written in a variety of languages. Conversely, an Intel® Visual Fortran subprogram (including those contained within a DLL or static library) can be called from a main program written in another language.

Microsoft Visual Studio* projects support a single language; therefore, code for each language must exist in its own project.

This topic summarizes mixed language compatibility with Intel® Visual Fortran for both managed code and unmanaged code. Managed code is architecture-independent code that runs under the control of the Microsoft* .NET Common Language Runtime Environment; unmanaged code is native, architecture-specific code.

Mixed-language applications can supply programs in a variety of formats:

Format	Created by	Callable by:
Compiled objects (.OBJ) and static libraries (.LIB) **NOTE** Objects and libraries must be link-compatible and not have conflicting names in their language support libraries	Intel® Visual Fortran, Intel® C++, Microsoft Visual C++* (unmanaged)	Intel® Visual Fortran, Intel® C++, Microsoft Visual C++* (unmanaged)
Dynamic Link Library (.DLL)	Intel® Visual Fortran, Intel® C++, Microsoft Visual C++* (unmanaged), Microsoft Visual Basic* (unmanaged), many more	Intel® Visual Fortran, Intel® C++, Microsoft Visual C++* (both managed and unmanaged), Microsoft Visual Basic* (managed and unmanaged), many others
.NET managed code assembly	Microsoft Visual C++ .NET, Microsoft Visual Basic .NET, other .NET languages	Intel® Visual Fortran (with interface generated by Fortran Module Wizard), .NET languages

Passing Arguments in Mixed-Language Programming

By default, Fortran programs pass arguments by reference; that is, they pass a pointer to each actual argument rather than the value of the argument. C programs typically pass arguments by value. Consider the following:

- When a Fortran program calls a C function, the C function's formal arguments must be declared as pointers to the appropriate data type.
- When a C program calls a Fortran subprogram, each actual argument must be specified explicitly as a pointer.

You can pass data between Fortran and C/C++ using argument lists just as you can within each language (for example, the argument list `a`, `b` and `c` in `CALL MYSUB(a,b,c)`). There are two ways to pass individual arguments:

- *By value*, which passes the argument's value.
- *By reference*, which passes the address of the arguments. On systems based on IA-32 architecture, Fortran, C, and C++ use 4-byte addresses. On systems based on Intel® 64 architecture, these languages use 8-byte addresses.

You need to make sure that for every call, the calling program and the called routine agree on how each argument is passed. Otherwise, the called routine receives bad data.

The Fortran technique for passing arguments changes depending on the calling convention specified. By default, Fortran passes all data by reference (except the hidden length argument of strings, which is passed by value).

On Windows* systems using IA-32 architecture only, you can alter the default calling convention. You can use either the `/iface:stdcall` option (`stdcall`) or the `/iface:cvf` option (Compaq* and Powerstation compatibility) to change the default calling convention, or the `VALUE` or `C` attributes in an explicit interface using the ATTRIBUTES directive. For more information on the ATTRIBUTES directive, see the Intel® Fortran Language Reference.

Both options cause the routine compiled and routines that it calls to have a @<*n*> appended to the external symbol name, where n is the number of bytes of all parameters. Both options assume that any routine called from a Fortran routine compiled this way will do its own stack cleanup, "callee pops." `/iface:cvf` also changes the way that `CHARACTER` variables are passed. With `/iface:cvf`, `CHARACTER` variables are passed as address/length pairs (that is, `/iface:mixed_str_len_arg`).

Handling Fortran Array Pointers and Allocatable Arrays

Stack Considerations in Calling Conventions (Windows*)

In the C calling convention, which is the default, the calling routine always adjusts the stack immediately after the called routine returns control. This produces slightly larger object code because the code that restores the stack must exist at every point a procedure is called.

> **NOTE**
> For 32-bit applications, use of the STDCALL calling convention means that the called procedure controls the stack. The code to restore the stack resides in the called procedure, so the code needs to appear only once. For 64-bit applications, the stack adjustment and @n name suffix features of STDCALL are not used.

The C calling convention makes calling with a variable number of arguments possible. In the C calling convention, the caller cleans up the stack, so it is possible to write a routine with a variable number of arguments. Therefore, the return point has the same address relative to the frame pointer, regardless of how many arguments are actually passed. Because of this, when the calling routine controls the stack, it knows how many arguments it passed, how big they are and where they reside in the stack. It can skip passing an argument and still keep track.

You can call routines with a variable number of arguments by including the ATTRIBUTES C option in your interface to a routine.

Naming Conventions

Naming conventions are as follows:

- A leading (prefix) underscore for Windows* operating systems based on IA-32 architecture; no underscores for Windows* operating systems based on other architectures.
- A trailing (postfix) underscore for all Linux* operating systems
- Leading and trailing underscores for all macOS* operating systems

C/C++ Naming Conventions

By default, the Fortran compiler converts function and subprogram names to lower case for Linux* and macOS* and upper case for Windows*. The C compiler never performs case conversion. A C procedure called from a Fortran program must, therefore, be named using the appropriate case.

C++ uses the same calling convention and argument-passing techniques as C, but naming conventions differ because of C++ decoration of external symbols. When the C++ code resides in a `.cpp` file, C++ name decoration semantics are applied to external names, often resulting in linker errors. The extern "C" syntax makes it possible for a C++ module to share data and routines with other languages by causing C++ to drop name decoration.

The following example declares `prn` as an external function using the C naming convention. This declaration appears in C++ source code:

```
extern "C" { void prn(); }
```

To call functions written in Fortran, declare the function as you would in C and use a "C" linkage specification. For example, to call the Fortran function FACT from C++, declare it as follows:

```
extern "C" { int fact( int* n ); }
```

The extern "C" syntax can be used to adjust a call from C++ to other languages, or to change the naming convention of C++ routines called from other languages. However, extern "C" can only be used from within C ++. If the C++ code does not use extern "C" and cannot be changed, you can call C++ routines only by determining the name decoration and generating it from the other language. Such an approach should only be used as a last resort, because the decoration scheme is not guaranteed to remain the same between versions.

When using extern "C" in a C++ program, keep in mind the following restrictions:

- You cannot declare a member function with extern "C".
- You can specify extern "C" for only one instance of an overloaded function; all other instances of an overloaded function have C++ linkage.

Compiling and Linking Intel® Fortran/C Programs

Your application can contain both C and Fortran source files. If your main program is a Fortran source file (`myprog.for`) that calls a routine written in C (`cfunc.c`), you can use the following sequence of commands to build your application.

Linux* and macOS*:

```
icc -c cfunc.c
ifort -o myprog myprog.for cfunc.o
```

Windows*:

```
icl /c cfunc.c
ifort myprog.for cfunc.obj
 /link /out:myprog.exe
```

The `icc` or `icl` command for Intel® C++ or the `cl` command (for Microsoft Visual C++*) compiles `cfunc.c`. The `-c` or `/c` option specifies that the linker is not called. This command creates `cfunc.o` (Linux* and macOS*) or `cfunc.obj` (Windows*).

The ifort command compiles `myprog.for` and links `cfunc.o` (Linux* and macOS*) or `cfunc.obj` (Windows*) with the object file created from `myprog.for` to create the executable.

Additionally, on Linux* and macOS* systems, you may need to specify one or more of the following options:

- Use the `-cxxlib` compiler option to tell the compiler to link using the C++ run-time libraries. By default, C++ libraries are not linked with Fortran applications.
- Use the `-fexceptions` compiler option to enable C++ exception handling table generation so C++ programs can handle C++ exceptions when there are calls to Fortran routines on the call stack. This option causes additional information to be added to the object file that is required during C++ exception handling. By default, mixed Fortran/C++ applications abort in the Fortran code if a C++ exception is thrown.

- Use the `-nofor_main` compiler option if your C/C++ program contains the `main()` entry point and is calling an Intel® Fortran subprogram, as shown in the following:

```
icc -c  cmain.c
ifort -nofor_main cmain.o fsub.f90
```

For more information about compiling and linking Intel® Fortran and C++ programs on Windows* operating systems, and the libraries used, see Specifying Consistent Library Types.

Building Intel® Fortran/C Mixed-Language Programs (Windows*)

When you understand and reconcile the calling, naming and argument passing conventions between Fortran and C, you are ready to build an application.

If you are using Microsoft Visual C++* or Intel® C++, you can edit, compile and debug your code within the Microsoft integrated development environment. If you are using another C compiler, you can edit your code within the integrated development environment. However, you must compile your code outside the integrated development environment and either build the Fortran/C program on the command line or add the compiled C `.OBJ` file to your Fortran project in the Microsoft IDE.

As an example of building from the command line, if you have a main C program `CMAIN.C` that calls Fortran subroutines contained in `FORSUBS.F90`, you can create the `CMAIN` application with the following commands:

```
icl /c cmain.c
ifort cmain.obj forsubs.f90
```

Intel® Visual Fortran accepts an object file for the main program written in C and compiled by the C compiler. The compiler compiles the .F90 file and then has the linker create an executable file under the name `CMAIN.EXE` using the two object files.

Either compiler (C or Fortran) can do the linking, regardless of which language the main program is written in; however, if you use the Fortran compiler first, you must include `LIBIFCORE.LIB` and `IFCONSOL.LIB` with the C compiler, and you may experience some difficulty with the version of the runtime library used by the C compiler. For these reasons, you may prefer to use the C compiler first or specify your project settings for both Fortran and C so there is agreement on the C library to link against, making sure that your application links against only one copy of the C library.

If you are using the IDE to build your application, Fortran uses Fortran and C libraries depending on the information specified in the Fortran folder in **Project > Properties** (**Project Settings** dialog box). You can also specify linker settings with the Linker folder in the **Project Settings** dialog box.

In the Fortran folder, within the **Libraries** property page, the **RunTime Library** category determines the libraries selected.

Runtime Library	Fortran Link Library Used	C Link Library Used
Debug Single-Threaded	libifcore.lib	libcmtd.lib
Multithreaded	libifcoremt.lib	libcmt.lib
Debug Multithreaded	libifcoremt.lib	libcmtd.lib
Debug Single-Threaded DLL	libifcorertd.lib (libifcorertd.dll)	msvcrt.lib (msvcrt.dll)
Multithreaded DLL	libifcoremd.lib (libifcoremd.dll)	msvcrt.lib (msvcrt.dll)
Debug Multithreaded DLL	libifcoremdd.lib (libifcoremdd.dll)	msvcrt.lib (msvcrt.dll)

For example, select Debug Multi-threaded DLL in the Run-time Library list to specify that DLL (`/libs:DLL`), multi-threaded (`/threads`), and debug (`/dbglibs`) libraries should be linked against, namely Fortran import library `libifcoremdd.lib` and its DLL library `libifcoremdd.dll` and C/C++ import library `msvcrtd.lib` and its DLL library `msvcrtd.dll`.

A mixed language solution containing a Fortran library project should have **Disable Default Library Search Rules** set to No in the IDE. To check this setting, choose **Project > Properties** and then choose the Libraries category. If you change the **Disable Default Library Search Rules** setting to Yes, you will need to explicitly add the needed runtime libraries to the non-Fortran project. If you are adding libraries explicitly, make sure you add `IFCONSOL.LIB` to the libraries of the non-Fortran project. This library is needed to perform almost any kind of I/O with Intel® Visual Fortran.

When you have a C++ main program and a Fortran library subproject, you need to manually add the library path to the Intel® Visual Fortran LIB folder. You only need to do this once per user. To add the path, choose **Tools > Options > Projects and Solutions > VC++ Directories**. Use the **Show directories for:** dropdown item to select Library files. Add the path to the displayed list.

The way Microsoft Visual C++* chooses libraries is also based upon the **Project > Properties** item, but within the **C/C++** tab. In the **Code Generation** category, the Run-time library item lists the following C libraries:

Menu Item Selected	CL Option or Project Type Enabled	Default Library Specified in Object File
Multithreaded	/MTd	libcmt.lib
Multithreaded DLL	/MD	msvcrt.lib (msvcrnn.dll)
Debug Multithreaded	/MTd	libcmtd.lib
Debug Multithreaded DLL	/MDd	msvcrtd.lib (msvcrtd.dll)

You must take care to choose the same type of run-time libraries in both your Fortran and C project. For example, if you select Multithreaded DLL in your Fortran project, you must select Multithreaded DLL in your C project. Otherwise, when your build your mixed Fortran/C application, you will receive errors from the Linker regarding undefined and/or duplicate symbols.

If you are using Microsoft Visual C++* or Intel® C++ , the Microsoft integrated development environment can build mixed Fortran/C applications transparently, with no special directives or steps on your part. You can edit and browse your C and Fortran programs with appropriate syntax coloring for the language. You need to place your Fortran source files into a Fortran project and your C/C++ files into a Visual C++* project.

When you debug a mixed Visual C++/Fortran application, the debugger will adjust to the code type as it steps through: the C or Fortran expression evaluator will be selected automatically based on the code being debugged, and the stack window will show Fortran data types for Fortran procedures and C data types for C procedures.

Implementation Specifics

Fortran Module Naming Conventions

Fortran module entities (data and procedures) have external names that differ from other external entities. Module names use the convention:

```
modulename_mp_entity_(Linux* OS and macOS*)
_MODULENAME_mp_ENTITY(Windows* OS)
```

modulename is the name of the module. For Windows* operating systems, the name is uppercase by default.

entity is the name of the module procedure or module data contained within *MODULENAME*. For Windows* operating systems, *ENTITY* is uppercase by default.

*_mp_* is the separator between the module and entity names and is always lowercase (except when the `assume std_mod_proc_name` compiler option or `standard-semantics` compiler option is used).

For example:

```
   MODULE mymod
     INTEGER a
  CONTAINS
     SUBROUTINE b (j)
        INTEGER j
     END SUBROUTINE
  END MODULE
```

This results in the following symbols being defined in the compiled object file on Linux* operating systems. (On macOS* operating systems, the symbols would begin with an underscore.)

```
mymod_mp_a_
mymod_mp_b_
```

The following symbols are defined in the compiled object file on Windows* operating systems based on IA-32 architecture:

```
_MYMOD_mp_A
_MYMOD_mp_B
```

On Windows* operating systems based on Intel® 64 architecture, there is no beginning underscore.

Handling Fortran Array Pointers and Allocatable Arrays

When a Standard Fortran array pointer or array is passed to another language, either its descriptor or its base address can be passed.

The following affects how Standard Fortran array pointers and arrays are passed:

- The ATTRIBUTES properties in effect
- The INTERFACE, if any, of the procedure they are passed to

If the INTERFACE declares the array pointer or array with deferred shape (for example, `ARRAY(:)`), its descriptor is passed. If the INTERFACE declares the array pointer or array with fixed shape, or if there is no interface, the array pointer or array is passed by base address as a contiguous array, which is like passing the first element of an array for contiguous array slices.

Use of the REFERENCE attribute on an array has no effect. Additionally, the VALUE attribute cannot be used with array arguments.

When you pass a Fortran array pointer or an array by descriptor to a non-Fortran routine, that routine needs to know how to interpret the descriptor. Part of the descriptor is a pointer to address space, such as a C pointer, and part of it is a description of the pointer or array properties, such as its rank, stride, and bounds.

For information about the Intel Fortran array descriptor format, see Handling Fortran Array Descriptors.

Standard Fortran array pointers and assumed-shape arrays are passed by passing the address of the array descriptor.

Standard Fortran pointers that point to scalar data contain the address of the data and are not passed by descriptor.

Handling Fortran Array Descriptors

For cases where Standard Fortran needs to keep track of more than a pointer memory address, the Intel® Fortran Compiler uses an *array descriptor*, which stores the details of how an array is organized.

When using an explicit interface (by association or procedure interface block), the compiler generates a descriptor for the following types of array arguments:

- Fortran array pointers
- Assumed-shape arrays
- Allocatable arrays
- Coarrays

- Class objects

Certain types of arguments do not use a descriptor, even when an appropriate explicit interface is provided. For example, explicit-shape and assumed-size arrays do not use a descriptor. In contrast, array pointers and allocatable arrays use descriptors regardless of whether they are used as arguments.

When calling between Intel® Fortran and C/C++, use an *implicit* interface, which allows the array argument to be passed *without* an Intel® Fortran descriptor. However, for cases where the called routine needs the information in the Intel® Fortran descriptor, declare the routine with an *explicit* interface and specify the dummy array as either an assumed-shape array or with the pointer attribute.

You can associate a Fortran array pointer with any piece of memory, organized in any way desired (as long as it is "rectangular" in terms of array bounds). You can also pass Fortran array pointers to the C language, and have it correctly interpret the descriptor to obtain the information it needs.

The downside to using array descriptors is that it can increase the opportunity for errors. Additionally, the corresponding code is not portable. Specifically:

- If the descriptor is not defined correctly, the program may access the wrong memory address, possibly causing a General Protection Fault.
- Array descriptor formats are specific to each Fortran compiler. Code that uses array descriptors is not portable to other compilers or platforms.
- The array descriptor format may change in the future.
- If the descriptor was built by the compiler, it cannot be modified by the user. Changing fields of existing descriptors is illegal.

The components of the current Intel® Fortran array descriptor on systems using IA-32 architecture are as follows:

- Bytes 0 to 3 contain the base address.
- Bytes 4 to 7 contain the size of a single element of the array.
- Bytes 8 to 11 are reserved and should not be explicitly set.
- Bytes 12 to 15 contain a set of flags used to store information about the array. This includes:
  - bit 1 (0x01): array is defined -- set if the array has been defined (storage allocated).
  - bit 2 (0x02): no deallocation allowed -- set if the array pointed to cannot be deallocated (that is, it is an explicit array target).
  - bit 3 (0x04): array is contiguous -- set if the array pointed to is a contiguous whole array or slice.
  - bit 8 (0x80): set if the array pointed to is ALLOCATABLE.
  - Other bits are reserved.
- Bytes 16 to 19 contain the number of dimensions (rank) of the array.
- Bytes 20 to 23 are reserved and should not be explicitly set.
- The remaining bytes contain information about each dimension (up to 31). Each dimension is described by a set of three 4-byte entities:
  - The number of elements (extent).
  - The distance between the starting address of two successive elements in this dimension, in bytes.
  - The lower bound.

An array of rank one requires three additional 4-byte entities for a total of nine 4-byte entities (6 + 3*1) and ends at byte 35. An array of rank seven is described in a total of twenty-seven 4-byte entities (6 + 3*7) and ends at byte 107.

Consider the Following Declaration

```
  integer,target :: a(10,10)
 integer,pointer :: p(:,:)
 p => a(9:1:-2,1:9:3)
 call f(p)
...
```

The descriptor for actual argument *p* would contain the following values:

- Bytes 0 to 3 contain the base address (assigned at run-time).
- Bytes 4 to 7 are set to 4 (size of a single element).
- Bytes 8 to 11 are reserved.

- Bytes 12 to 15 contain 3 (array is defined and deallocation is not allowed).
- Bytes 16 to 19 contain 2 (rank).
- Bytes 20 to 23 are reserved.
- Bytes 24 to 35 contain information for the first dimension, as follows:
  - 5 (extent).
  - -8 (distance between elements).
  - 9 (the lower bound).
- For the second dimension, bytes 36 to 47 contain:
  - 3 (extent).
  - 120 (distance between elements).
  - 1 (the lower bound).
- Byte 47 is the last byte for this example.

NOTE
The format for the descriptor on systems using Intel® 64 architecture is identical to that on systems using IA-32 architecture, except that all fields are 8-bytes long, instead of 4-bytes.

Returning Character Data Types

A discrepancy occurs when working with C and Fortran character strings: C strings are null-terminated while Fortran strings have known lengths. A C routine that returns a character string will be returning a pointer to a null-terminated string. A Fortran routine will not have any knowledge of the string's length.

If a Fortran routine is returning a string to a C program, the Fortran program must null-terminate the string.

Example of Returning Character Types from C to Fortran

The following shows the Fortran code that declares interfaces to a C routine and calls the C routine. In the example, the pointer returned by the C routine can be passed along to another C routine. However, it is not usable by Fortran as-is since Fortran has no knowledge of the string's length.

Fortran Code Example

```
! This program declares a C program that returns a char*
!  calls it, and has to pass that return value along to
!  a different c program because type(c_ptr) is limited
!  in a pure Fortran program.

program FCallsCReturnsCptr

use, intrinsic :: iso_c_binding

! declare the interfaces to the C routines

interface
   type(C_PTR)function my_croutine1 ( input) bind(c)
     import
     integer(c_int), value :: input
   end function my_croutine1

   subroutine my_cprint( string ) bind(c)
     import c_ptr
     type(C_PTR), value :: string
   end subroutine my_cprint
end interface
```

Fortran Code Example

```
   call my_cprint(my_croutine1(42))

end program
```

Called C Routine Example

```
#include <stdio.h>

char *my_croutine1 (int input) {
   static char temp[30];
   temp[0] = '\0';
   sprintf(temp, "in routine, you said %d", input);
  return temp;
}

void my_cprint (char *string) {
  printf ("cprint says %s\n", string);
 return;
}
```

The example above shows the C code used to call a Fortran routine. The Fortran routine returns a string that is then printed by the C program. As shown in the example, it is relatively straightforward to pass a string back to C from Fortran. Additionally, the string can be easily used by the C program because it is NULL-terminated.

In the above example, the following restrictions and behaviors apply:

- The function's length and result do not appear in the call statement; they are added by the compiler.
- The called routine must copy the result string into the location specified by `result`; it must not copy more than `length` characters.
- If fewer than `length` characters are returned, the return location should be padded on the right with blanks; Fortran does not use zeros to terminate strings.
- The called procedure is type `void`.

Example of Returning Character Types from Fortran to C

The following shows the C code used to call a Fortran routine; the Fortran routine returns a string that is then printed by the C program.

C Code Example

```
#include <stdio.h>

char *GetFortranWords(void);

int main() {

   printf ("Fortran says this: %s\n", GetFortranWords());
   return 0;
}
```

Called Fortran Routine Example

```
! this routine is called from C, returning a string that
!  can be printed by the caller

function GetFortranWords bind(c, name="GetFortranWords")
use, intrinsic :: iso_c_binding
type(C_ptr) :: GetFortranWords
character*30 returnval

returnval = "I like to type words!" // char(0)

GetFortranWords = C_LOC(returnval)
return
end
```

Legacy Extensions

ATTRIBUTES

Standard Fortran provides a syntax for interoperating with C, including applying the appropriate naming conventions. You can use BIND(C) for interoperability with C, instead of specifying ATTRIBUTES options.

The ATTRIBUTES options (also known as properties) C, STDCALL (Windows* only), REFERENCE, VALUE affect the calling convention of routines. You can specify:

- The C, STDCALL, and REFERENCE properties for an entire routine.
- The VALUE and REFERENCE properties for individual arguments.

By default, Fortran passes all data by reference (except the hidden length argument of strings, which is passed by value). If the C (or, for Windows*, STDCALL) option is used, the default changes to passing almost all data except arrays by value. However, in addition to the calling-convention options C and STDCALL, you can specify argument options, VALUE and REFERENCE, to pass arguments by value or by reference, regardless of the calling convention option. Arrays can only be passed by reference.

Different Fortran calling conventions can be specified by declaring the Fortran procedure to have certain attributes.

The following table summarizes the effect of the most common Fortran calling convention directives.

Calling Conventions for ATTRIBUTES Options

Argument	Default	C	C, REFERENCE	STDCALL (Windows* IA-32 architecture)	STDCALL, REFERENCE (Windows* IA-32 architecture)
Scalar	Reference	Value	Reference	Value	Reference
Scalar [value]	Value	Value	Value	Value	Value
Scalar [reference]	Reference	Reference	Reference	Reference	Reference

Argument	Default	C	C, REFERENCE	STDCALL (Windows* IA-32 architecture)	STDCALL, REFERENCE (Windows* IA-32 architecture)
String	Reference, either Len:End or Len:Mixed	String(1:1)	Reference, either Len:End or Len:Mixed	String(1:1)	String(1:1)
String [value]	Error	String(1:1)	String(1:1)	String(1:1)	String(1:1)
String [reference]	Reference, either No Len or Len:Mixed	Reference, No Len	Reference, No Len	Reference, No Len	Reference, No Len
Array	Reference	Reference	Reference	Reference	Reference
Array [value]	Error	Error	Error	Error	Error
Array [reference]	Reference	Reference	Reference	Reference	Reference
Derived Type	Reference	Value, size dependent	Reference	Value, size dependent	Reference
Derived Type [value]	Value, size dependent	Value, size dependent	Value, size dependent	Value, size dependent	Value, size dependent
Derived Type [reference]	Reference	Reference	Reference	Reference	Reference
F90 Pointer	Descriptor	Descriptor	Descriptor	Descriptor	Descriptor
F90 Pointer [value]	Error	Error	Error	Error	Error
F90 Pointer [reference]	Descriptor	Descriptor	Descriptor	Descriptor	Descriptor
Naming Conventions					
Prefix	_ (Windows* operating systems using IA-32 architecture, macOS* operating systems) *none* for all others	_ (Windows* operating systems using IA-32 architecture, macOS* operating systems) *none* for all others	_ (Windows* operating systems using IA-32 architecture, macOS* operating systems) *none* for all others	_	_
Suffix	none (Windows*)	*none*	*none*	@*n*	@*n*

Argument	Default	C	C, REFERENCE	STDCALL (Windows* IA-32 architecture)	STDCALL, REFERENCE (Windows* IA-32 architecture)
	_ (Linux*, macOS*)				
Case	Upper Case (Windows*) Lower Case (Linux*, macOS*)	Lower Case	Lower Case	Lower Case	Lower Case
Stack Cleanup	Caller	Caller	Caller	Callee	Callee

The terms in the above table mean the following:

[value]	Argument assigned the VALUE attribute.
[reference]	Argument assigned the REFERENCE attribute.
Value	The argument value is pushed on the stack. All values are padded to the next 4-byte boundary.
Reference	On systems using IA-32 architecture, the 4-byte argument address is pushed on the stack. On systems using Intel® 64 architecture, the 8-byte argument address is pushed on the stack.
Len:End or Len:Mixed	For certain string arguments: • Len:End applies when `-nomixed-str-len-arg` (Linux* and macOS*) or `/iface:nomixed_str_len_arg` (Windows*) is set. The length of the string is pushed (by value) on the stack after all of the other arguments. This is the default. • Len:Mixed applies when `-mixed-str-len-arg` (Linux* and macOS*) or `/iface:mixed_str_len_arg` (Windows*) is set. The length of the string is pushed (by value) on the stack immediately after the address of the beginning of the string.
No Len or Len:Mixed	For certain string arguments: • No Len applies when `-nomixed-str-len-arg` (Linux* and macOS*) or `/iface:nomixed_str_len_arg` (Windows*) is set. The length of the string is not available to the called procedure. This is the default. • Len:Mixed applies when `-mixed-str-len-arg` (Linux* and macOS*) or `/iface:mixed_str_len_arg` (Windows*) is set. The length of the string is pushed (by value) on the stack immediately after the address of the beginning of the string.
No Len	For string arguments, the length of the string is not available to the called procedure.
String(1:1)	For string arguments, the first character is converted to INTEGER(4) as in ICHAR(string(1:1)) and pushed on the stack by value.
Error	Produces a compiler error.
Descriptor	On systems using IA-32 architecture, the 4-byte address of the array descriptor. On systems using Intel® 64 architecture, the 8-byte address of the array descriptor.

@*n*	On systems using IA-32 architecture, the at sign (@) followed by the number of bytes (in decimal) required for the argument list.
Size dependent	On systems using IA-32 architecture, derived-type arguments specified by value are passed as follows: • Arguments from 1 to 4 bytes are passed by value. • Arguments from 5 to 8 bytes are passed by value in two registers (two arguments). • Arguments more than 8 bytes provide value semantics by passing a temporary storage address by reference.
Upper Case	Procedure name in all uppercase.
Lower Case	Procedure name in all lowercase.
Callee	The procedure being called is responsible for removing arguments from the stack before returning to the caller.
Caller	The procedure doing the call is responsible for removing arguments from the stack after the call is over.

You can use the BIND(C, name=<string>) attribute to resolve discrepancies with C. Alternatively, the ALIAS option can be used with any other Fortran calling-convention option to preserve mixed-case names. +

For Windows* operating systems, the compiler option `/iface` also establishes some default argument passing conventions. The `/iface` compiler option has the following choices:

Option	How are arguments passed?	Append `@n` to names on systems using IA-32 architecture?	Who cleans up stack?	Varargs support?
/iface:cref	By reference	No	Caller	Yes
/iface:stdref	By reference	Yes	Callee	No
/iface:default	By reference	No	Caller	Yes
/iface:c	By value	No	Caller	Yes
/iface:stdcall	By value	Yes	Callee	No
/iface:cvf	By reference	Yes	Callee	No

NOTE
The following applies to Windows*: When interfacing to the Windows* graphical user interface or making API calls, you will typically use STDCALL.

ALIAS

Use the ALIAS option for the ATTRIBUTES directive If the name of a routine appears as mixed-case in C and you need to preserve the case.

To use the ALIAS option, place the name in quotation marks exactly as it is to appear in the object file.

C Function `My_Proc` Example

```
!DIR$ ATTRIBUTES DECORATE,ALIAS:'My_Proc'
:: My_Proc
```

This example uses DECORATE to automatically reconcile external name declaration for the target platform.

Using the DECORATE option in combination with the ALIAS option specifies that the external name specified in ALIAS should have the correct prefix and postfix decorations for the calling mechanism in effect.

Compiler Options

Using the -nofor-main Compiler Option (Linux* and macOS*)

Intel® Fortran subprograms can be called by C/C++ main programs. Use the `-nofor-main` compiler option if your C/C++ program contains the `main()` entry point and is calling an Intel® Fortran subprogram.

`nofor-main` compiler option

Error Handling

Handling Compile Time Errors

Understanding Errors During the Build Process

The Intel® Fortran Compiler identifies syntax errors and violations of language rules in the source program.

Compiler Diagnostic Messages

These messages describe diagnostics that are reported during the processing of the source file. Compiler diagnostic messages usually provide enough information for you to determine the cause of an error and correct it. These messages generally have the following format:

```
filename(linenum): severity #error number: message
```

Diagnostic	Meaning
filename	Indicates the name of the source file currently being processed.
linenum	Indicates the source line where the compiler detects the condition.
severity	Indicates the severity of the diagnostic message: *Warning*, *Error*, or *Fatal error*.
message	Describes the problem.

The following is an example of an error message:

```
echar.for(7): error #6321: An unterminated block exits.
       DO I=1,5
-------^
```

The pointer (`---^`) indicates the place on the source program line where the error was found, in this case where an END DO statement was omitted.

To view the passes as they execute on the command line, specify the `watch` compiler option.

NOTE
You can perform compile-time procedure interface checking between routines with no explicit interfaces present. To do this, generate a module containing the interface for each compiled routine using the `gen-interfaces` option and check implicit interfaces using the `warn[:]interfaces` compiler option.

Controlling Compiler Diagnostic Warning and Error Messages

You can use a number of compiler options to control the diagnostic messages issued by the compiler. For example, compiler option `WB` turns compile time bounds errors into warnings. To control compiler diagnostic messages (such as warning messages), use the `warn` option. This option controls warnings issued by the compiler and supports a wide range of *keyword*s. Some of these are as follows:

- **[no]alignments:** Determines whether warnings occur or do not occur for data that is not naturally aligned.
- **[no]declarations:** Determines whether warnings occur or do not occur for any undeclared symbols.
- **[no]errors:** Determines whether warning-level messages are changed or are not changed to error-level messages.
- **[no]general:** Determines whether warning messages and informational messages are issued or are not issued by the compiler.
- **[no]interfaces:** Determines whether warnings about the interfaces for all called SUBROUTINES and invoked FUNCTIONS are issued or are not issued by the compiler.
- **[no]stderrors:** Determines whether warnings about Fortran standard violations are changed or are not changed tto errors.
- **[no]truncated_source:** Determines whether warnings occur or do not occur when source exceeds the maximum column width in fixed-format files.

For more information, see the warn compiler option.

You can also control the display of diagnostic information with variations of the `-diag` (Linux* and macOS*) or `/Qdiag` (Windows*) compiler option. This option accepts numerous arguments and values, allowing you wide control over displayed diagnostic messages and reports.

Some of the most common variations include the following:

Linux* and macOS*	Windows*	Description
`-diag-enable=`*list*	`/Qdiag-enable:`*list*	Enables a diagnostic message or a group of messages
`-diag-disable=`*list*	`/Qdiag-disable:`*list*	Disables a diagnostic message or a group of messages
`-diag-warning=`*list*	`/Qdiag-warning:`*list*	Tells the compiler to change diagnostics to warnings

Linux* and macOS*	Windows*	Description
`-diag-error=`*list*	`/Qdiag-error:`*list*	Tells the compiler to change diagnostics to errors
`-diag-remark=`*list*	`/Qdiag-remark:`*list*	Tells the compiler to change diagnostics to remarks (comments)

The *list* items can be one of the keywords `warn`, `remark`, or `error`, a keyword specifying a certain group (`par`, `vec`, `driver`, `cpu-dispatch`), or specific diagnostic IDs separated by commas. For more information, see diag, Qdiag.

Additionally, you can use the following related options:

Linux* and macOS*	Windows*	Description
`-diag-dump`	`/Qdiag-dump`	Tells the compiler to print all enabled diagnostic messages and stop compilation.
`-diag-file[=`*file*`]`	`/Qdiag-file[:`*file*`]`	Causes the results of diagnostic analysis to be output to a file.
`-diag-file-append[=`*file*`]`	`/Qdiag-file-append[:`*file*`]`	Causes the results of diagnostic analysis to be appended to a file.
`-diag-error-limit=`*n*	`/Qdiag-error-limit:`*n*	Specifies the maximum number of errors allowed before compilation stops.

Linker Diagnostic Errors

If the linker detects any errors while linking object modules, it displays messages about their cause and severity. If any errors occur, the linker does not produce an executable file. Linker messages are descriptive, and you do not normally need additional information to determine the specific error.

To view the libraries being passed to the linker on the command line, specify the `watch` option.

Error Severity Levels

Comment Messages

These messages indicate valid but inadvisable use of the language being compiled. The compiler displays comments by default. You can suppress comment messages with the `warn[:]nousage` option.

Comment messages do not terminate translation or linking, they do not interfere with any output files either. Some examples of the comment messages are:

```
Null CASE construct
The use of a non-integer DO loop variable or expression
Terminating a DO loop with a statement other than CONTINUE or ENDDO
```

Warning Messages

These messages report valid but questionable use of the language being compiled. The compiler displays warnings by default. You can suppress warning messages by using the `nowarn` option. Warnings do not stop translation or linking. Warnings do not interfere with any output files. Some representative warning messages are:

```
constant truncated - precision too great
non-blank characters beyond column 72 ignored
Hollerith size exceeds that required by the context
```

Error Messages

These messages report syntactic or semantic misuse of Fortran. Errors suppress object code for the file containing the error and prevent linking, but they do not stop the compiler from scanning for any other errors. Some typical examples of error messages are:

```
line exceeds 132 characters
unbalanced parenthesis
incomplete string
```

Fatal Errors

Fatal messages indicate environmental problems. Fatal error conditions stop translation, assembly, and linking. If a fatal error ends compilation, the compiler displays a termination message on standard error output. Some representative fatal error messages are:

```
Disk is full, no space to write object file
Too many segments, object format cannot support this many segments
```

Using the Command Line

If you are using the command line, messages are written to the standard error output file. When using the command line:

- Make sure that the appropriate environment variables have been set by executing the `compilervars.sh` (Linux* and macOS*) or `compilervars.bat` (Windows*) file. For Windows*, these environment variables are preset if you use the Fortran Command Prompt window in the Intel® Visual Fortran program folder. For a list of environment variables used by the `ifort` command during compilation, see Supported Environment Variables.
- Specify the libraries to be linked against using compiler options.
- You can specify libraries (include the path, if needed) as file names on the command line.

Using the Visual Studio IDE (Windows*)

If you are using the Microsoft* Visual Studio* integrated development environment (IDE), compiler and linker errors are displayed in the **Build** pane of the **Output** window. To display the **Output** window, choose **View** > **Other Windows** > **Output**. You can also use the **Task List** window (**View** > **Other Windows** > **Task List**) to view display links to problems encountered during the build process. Click these tasks to jump to code that caused build problems. You can also check the Build log for more information.

To quickly locate the source line causing the error, follow these steps:

1. Double-click the error message text in the **Build** pane of the **Output** window.

   - or -
2. Press **F8**. The editor window appears with a marker in the left margin that identifies the line causing the error. You can continue to press **F8** to scroll through additional errors.

After you have corrected any compiler errors reported during the previous build, choose **Build project name** from the **Build** menu. The build engine recompiles only those files that have changed, or which refer to changed include or module files. If all files in your project compile without errors, the build engine links the object files and libraries to create your program or library.

You can force the build engine to recompile all source files in the project by selecting **Rebuild project name** from the **Build** menu. This is useful to verify that all of your source code is clean, especially if you are using a makefile, or if you use a new set of compiler options for all of the files in your project.

When using the IDE:

- Make sure that you have specified the correct path, library, and include directories. For more information, see Specifying Path Library and Include Directories.

- If a compiler option is not available through **Project** > **Properties** in the Intel® Fortran Property pages, you can type the option in the Command Line category. Use the lower part of the window under **Additional Options**, just as you would using the command line. For example, you can enter the linker option `/link /DEFAULTLIB` to specify an additional library.

> **NOTE**
> If you have a question about a compile-time error, please submit your question to the Intel® Fortran forum, which can be found at https://software.intel.com/en-us/forum.

Handling Run-Time Errors

Understanding Run-Time Errors

During execution, your program may encounter errors or exception conditions. These conditions can result from any of the following:

- Errors that occur during I/O operations.
- Invalid input data.
- Argument errors in calls to the mathematical library.
- Arithmetic errors.
- Other system-detected errors.

The Intel® Fortran Run-Time Library (RTL) generates appropriate messages and takes action to recover from errors whenever possible.

For a description of each Intel® Fortran run-time error message, see List of Run-Time Error Messages.

There are a few tools and aids that are useful when an application fails and you need to diagnose the error. Compiler-generated machine code listings and linker-generated map files can help you understand the effects of compiler optimizations and to see how your application is laid out in memory. They may help you interpret the information provided in a stack trace at the time of the error. See Generating Listing and Map Files.

Forcing a Core Dump for Severe Errors

You can force a core dump for severe errors that do not usually cause a `core` file to be created. Before running the program, set the `FOR_DUMP_CORE_FILE` environment variable to TRUE to cause severe errors to create a `core` file. See the "Supported Environments Variables" topic for valid values of TRUE and FALSE.

For instance, the following C shell command sets the `FOR_DUMP_CORE_FILE` environment variable:

```
setenv FOR_DUMP_CORE_FILE y
```

The `core` file is written to the current directory and can be examined using a debugger.

NOTE
If you requested a core file to be created on severe errors and you do not get one when expected, the problem might be that your process limit for the allowable size of a core file is set too low (or to zero). See the man page for your shell for information on setting process limits. For example, the C shell command limit (with no arguments) will report your current settings, and `limit coredumpsize unlimited` will raise the allowable limit to your current system maximum.

Run-Time Default Error Processing

The Intel® Fortran run-time system processes a number of errors that can occur during program execution. A default action is defined for each error recognized by the Intel® Fortran run-time system. The default actions described throughout this section occur unless overridden by explicit error-processing methods.

The way in which the Intel® Fortran run-time system actually processes errors depends upon the following factors:

- The severity of the error. For instance, the program usually continues executing when an error message with a severity level of warning or info (informational) is detected.
- For certain errors associated with I/O statements, whether or not an I/O error-handling specifier was specified.
- For certain errors, whether or not the default action of an associated signal was changed.
- For certain errors related to arithmetic operations (including floating-point exceptions), compilation options can determine whether the error is reported and the severity of the reported error.

How arithmetic exception conditions are reported and handled depends on the cause of the exception and how the program was compiled. Unless the program was compiled to handle exceptions, the exception might not be reported until *after* the instruction that caused the exception condition.

Run-Time Message Display and Format

When errors occur during execution (run time) of a program, the Intel® Visual Fortran run-time system issues diagnostic messages.

The location where Fortran run-time messages are displayed depends on the Understanding Project Types:

Project Type	Where Messages Appear
Fortran Console applications	Run-time error messages are displayed on the standard error device (unless redirected).
Fortran QuickWin and Fortran Standard Graphics applications	Run-time error messages are displayed in a separate QuickWin message box.
Fortran Windows applications	Run-time error messages are displayed in a separate message box.

Fortran run-time messages have the following format:

```
forrtl:severity (number):message-text
```

where:

- ***forrtl*:** Identifies the source as the Intel® Fortran run-time system (Run-Time Library or RTL).
- ***severity*:** The severity levels are: *severe* , *error*, *warning*, or *info*
- ***number*:** This is the message number; see also the Using the IOSTAT Specifier and Fortran Exit Codes for I/O statements.
- ***message-text*:** Explains the event that caused the message.

The following table explains the severity levels of run-time messages, in the order of greatest to least severity. The severity of the run-time error message determines whether program execution continues:

Severity	Description
severe	Must be corrected. The program's execution is terminated when the error is encountered unless the program's I/O statements use the END, EOR, or ERR branch specifiers to transfer control, perhaps to a routine that uses the IOSTAT specifier. (See Using the END EOR and ERR Branch Specifiers and Using the IOSTAT Specifier and Fortran Exit Codes and Methods of Handling Errors.) For severe errors, stack trace information is produced by default, unless environment variable `FOR_DISABLE_STACK_TRACE` is set. When that environment variable is set, no stack trace information is produced. If compiler option `traceback` is specified on the command line, the stack trace information contains program counters set to symbolic information. Otherwise, the information only contains hexadecimal program counter information. In some cases stack trace information is also produced by the compiled code at run-time to provide details about the creation of array temporaries.
error	Should be corrected. The program might continue execution, but the output from this execution might be incorrect. For errors of severity type error, stack trace information is produced by default, unless the environment variable `FOR_DISABLE_STACK_TRACE` is set. When that environment variable is set, no stack trace information is produced. If the command line option `traceback` is specified, the stack trace information contains program counters set to symbolic information. Otherwise, the information only contains hexadecimal program counter information.

Severity	Description
	In some cases stack trace information is also produced by the compiled code at run-time to provide details about the creation of array temporaries.
warning	Should be investigated. The program continues execution, but output from this execution might be incorrect.
info	For informational purposes only; the program continues.

For a description of each Intel® Fortran run-time error message, see Run-Time Default Error Processing and related topics.

The following example applies to Linux* and to macOS*:

In some cases, stack trace information is produced by the compiled code at run time to provide details about the creation of array temporaries.

The following program generates an error at line 12:

```
program ovf
real*4 x(5),y(5)
integer*4 i

 x(1) = -1e32
 x(2) = 1e38
 x(3) = 1e38
 x(4) = 1e38
 x(5) = -36.0

do i=1,5
y(i) = 100.0*(x(i))
print *, 'x = ', x(i), ' x*100.0 = ',y(i)
end do
end
```

The following command line produces stack trace information for the program executable.

```
> ifort -O0 -fpe0 -traceback ovf.f90 -o ovf.exe
> ovf.exe

x =  -1.0000000E+32  x*100.0
 =  -1.0000000E+34
forrtl: error (72): floating overflow
Image        PC         Routine       Line      Source
ovf.exe      08049E4A   MAIN__            14    ovf.f90
ovf.exe      08049F08   Unknown       Unknown   Unknown
ovf.exe      400B3507   Unknown       Unknown   Unknown
ovf.exe      08049C51   Unknown       Unknown   Unknown
Abort
```

The following suppresses stack trace information because the `FOR_DISABLE_STACK_TRACE` environment variable is set.

```
> setenv FOR_DISABLE_STACK_TRACE true> ovf.exe

x =  -1.0000000E+32  x*100.0 =  -1.0000000E+34
forrtl: error (72): floating overflow
Abort
```

Run-Time Library Message Catalog File Location

The libifcore, libirc, and libm run-time libraries ship message catalogs. When a message by one of these libraries is to be displayed, the library searches for its message catalog in a directory specified by either the `NLSPATH` (Linux* and macOS*), or `%PATH%` (Windows*) environment variable. If the message catalog cannot be found, the message is displayed in English.

The names of the three message catalogs are as follows:

libifcore message catalogs and related text message files	Linux* and macOS*	`ifcore_msg.cat` `ifcore_msg.msg`
	Windows*	`ifcore_msg.dll` `ifcore_msg.mc`
libirc message catalogs and related text message files	Linux* and macOS*	`irc_msg.cat` `irc_msg.msg`
	Windows*	`irc_msg.dll` `irc_msg.mc`
libm message catalogs and related text message files	Linux* and macOS*	`libm.cat` `libm.msg`
	Windows*	`libmUI.dll` `libmUI.mc`

Values Returned at Program Termination

An Intel® Fortran program can terminate in a number of ways. On Linux* and macOS*, values are returned to the shell.

- The program runs to normal completion. A value of zero is returned.
- The program stops with a STOP or ERROR STOP statement. If an integer stop-code is specified, a status equal to the code is returned; if no stop-code is specified, a status of zero is returned.
- The program stops because of a signal that is caught but does not allow the program to continue. A value of '1' is returned.
- The program stops because of a severe run-time error. The error number for that run-time error is returned. See Understanding Run-Time Errors and related topics.
- The program stops with a CALL EXIT statement. The value passed to EXIT is returned.
- The program stops with a CALL ABORT statement. A value of '134' is returned.

See Also

Understanding Run-Time Errors

Methods of Handling Errors

Whenever possible, the Intel® Fortran RTL does certain error handling, such as generating appropriate messages and taking necessary action to recover from errors. You can explicitly supplement or override default actions by using the following methods:

- To transfer control to error-handling code within the program, use the END, EOR, and ERR branch specifiers in I/O statements. See Using the END EOR and ERR Branch Specifiers.
- To identify Fortran-specific I/O errors based on the value of Intel® Fortran RTL error codes, use the I/O status specifier (IOSTAT) in I/O statements (or call the ERRSNS subroutine). See Using the IOSTAT Specifier and Fortran Exit Codes.
- Obtain system-level error codes by using the appropriate library routines.
- For certain error conditions, use the signal handling facility to change the default action to be taken.

See Also

Using the IOSTAT Specifier and Fortran Exit Codes
Using the END EOR and ERR Branch Specifiers

Using the END, EOR, and ERR Branch Specifiers

When a severe error occurs during Intel® Fortran program execution, the default action is to display an error message and terminate the program. To override this default action, there are three branch specifiers you can use in I/O statements to transfer control to a specified point in the program:

- The END branch specifier handles an end-of-file condition.
- The EOR branch specifier handles an end-of-record condition for non-advancing reads.
- The ERR branch specifier handles all error conditions.

If you use the END, EOR, or ERR branch specifiers, no error message is displayed and execution continues at the designated statement, usually error-handling code.

You might encounter an unexpected error that the error-handling routine cannot handle. In this case, do one of the following:

- Modify the error-handling routine to display the error message number.
- Remove the END, EOR, or ERR branch specifiers from the I/O statement that causes the error.

After you modify the source code, compile, link, and run the program to display the error message. For example:

```
    READ (8,50,ERR=400)
```

If any severe error occurs during execution of this statement, the Intel® Visual Fortran RTL transfers control to the statement at label 400. Similarly, you can use the END specifier to handle an end-of-file condition that might otherwise be treated as an error. For example:

```
    READ (12,70,END=550)
```

When using non-advancing I/O, use the EOR specifier to handle the end-of-record condition. For example:

```
150 FORMAT (F10.2, F10.2, I6)
    READ (UNIT=20, FMT=150, SIZE=X, ADVANCE='NO', EOR=700) A, F, I
```

You can also use ERR as a specifier in an OPEN, CLOSE, or INQUIRE statement. For example:

```
    OPEN (UNIT=10, FILE='FILNAME', STATUS='OLD', ERR=999)
```

If an error is detected during execution of this OPEN statement, control transfers to the statement at label 999.

Using the IOSTAT Specifier and Fortran Exit Codes

The IOSTAT specifier can be used to continue program execution after an I/O error, or an end-of-file or end-of-record condition occurs, and to return information about the status of I/O operations. Certain error conditions are *not* returned in IOSTAT.

The IOSTAT specifier can supplement or replace the use of the END=, EOR=, and ERR= branch specifiers.

Use of an IOSTAT= specifier in an I/O statement prevents initiation of error termination if an error occurs during the execution of the I/O statement. The integer variable specified in the IOSTAT= specifier becomes defined during the execution of the I/O statement with the following values:

- 0 for normal completion of the I/O statement (no error, end-of-file, or end-of-record condition occurs).
- The value of the (negative) default integer scalar constant IOSTAT_EOR defined in the intrinsic module ISO_FORTRAN_ENV if no error condition or end-of-file condition occurs, but an end-of-record condition does occur during the execution of an input statement.
- The value of the (negative) default integer scalar constant IOSTAT_END defined in ISO_FORTRAN_ENV if no error condition occurs, but an end-of-file condition does occur during the execution of an input statement.
- For an INQUIRE statement, the value of the default integer constant IOSTAT_INQUIRE_INTERNAL_UNIT defined in ISO_FORTRAN_ENV if a file-unit-number identifies an internal unit in the execution of the statement.
- A positive integer value if an error condition occurs. (This value is one of the Fortran-specific IOSTAT numbers listed in the run-time error message. See List of Run-Time Error Messages, which lists the messages.)

Note that the value assigned to the IOSTAT variable is the same value that would be returned as an exit code if error termination was initiated.

Following the execution of the I/O statement and assignment of an IOSTAT value, control transfers to the END=, EOR=, or ERR= statement label, if any. If there is no control transfer, normal execution continues.

The non-standard include file FOR_ISODEF.FOR and the non-standard module FORISODEF contain symbolic constants for the values returned through an IOSTAT= specifier.

The following example uses the IOSTAT specifier and the module FORIOSDEF to handle an OPEN statement error (in the FILE specifier).

```
    USE foriosdef
    IMPLICIT NONE
    CHARACTER(LEN=40) :: FILNM
    INTEGER IERR
    PRINT *, 'Type file name:'
    READ (*,*) FILNM
    OPEN (UNIT=1, FILE=FILNM, STATUS='OLD', IOSTAT=IERR, ERR=100)
    PRINT *, 'Opening file: ', FILNM
    ! process the input file
    ...
    CLOSE (UNIT=1)
    STOP
100 IF(IERR . EQ. FOR$IOS_FILNOTFOU) THEN
       PRINT *, 'File: ', FILNM, ' does not exist '
    ELSE
       PRINT *, 'Unrecoverable error, code =', IERR
    END IF
    END PROGRAM
```

Another way to obtain information about an error is the ERRSNS subroutine, which allows you to obtain the last I/O system error code associated with an Intel® Fortran RTL error (see the *Intel® Fortran Language Reference*).

Locating Run-Time Errors

This topic provides some guidelines for locating the cause of exceptions and run-time errors. Intel® Fortran run-time error messages do not usually indicate the exact source location causing the error. The following compiler options are related to handling errors and exceptions:

- The `-check [keyword]` (Linux* and macOS*) or `/check[:keyword]` (Windows*) option generates extra code to catch certain conditions at run time.

  The keyword `bounds` generates code to perform compile-time and run-time checks on array subscript and character substring expressions. An error is reported if the expression is outside the dimension of the array or the length of the string.

  The keyword `uninit` generates code for dynamic checks of uninitialized variables. If a variable is read before written, a run-time error routine will be called.

  The keywords `noformat` and `nooutput_conversion`reduce the severity level of the associated run-time error to allow program continuation.

  The keyword `pointers` generates code to test for disassociated pointers and unallocatable arrays. The following `check[:]pointers` option examples result in various output messages.

  Example: Allocatable variable not allocated

```
real, allocatable:: a(:)
   !
   ! A is initially unallocated.  To allocate, use:
   !
   !    allocate(a(4))
   !
   ! Because A is unallocated, the next statement will
   ! issue an error in applications built with "check pointers".
   !
   a=17
   print  *,a
   end
Output 1:
forrtl: severe (408): fort: (8): Attempt to fetch from allocatable
                                 variable A when it is not allocated
```

  Example: Unassociated Pointer

```
   real, pointer:: a(:)
   allocate(a(5))
   a=17
   print  *,a
   deallocate(a)   ! Once A is deallocated, the next statement
                   ! issues an error in an application built
                   ! with "check pointers".
   a=20
   print  *,a
   end

Output 2:
```

```
   17.00000       17.00000       17.00000       17.00000       17.00000
forrtl: severe (408): fort: (7): Attempt to use pointer A when it is
                                 not associated with a target
```

Example: Cray pointer with zero value

```
   pointer(p,a)
   real, target:: b
   !
   ! P initially has no address assigned to it.  To assign an
   ! address, use:
   !
   !    p=loc(b)
   !
   ! Because P has no address assigned to it, the next
   ! statement will issue an error in an application built
   ! with "check pointers".
   !
   b=17.
   print  *,a
   end
Output 3:
forrtl: severe (408): fort: (9): Attempt to use pointee A when its
                                 corresponding integer
                                 pointer P has the value zero
```

- The `traceback` option generates extra information in the object file to provide source file traceback information when a severe error occurs at run time. This simplifies the task of locating the cause of severe run-time errors. Without the `traceback` option, you could try to locate the cause of the error using a map file and the hexadecimal addresses of the stack displayed when a severe error occurs. Certain traceback-related information accompanies severe run-time errors, as described in Traceback.
- The `fpe` option controls the handling of floating-point arithmetic exceptions (IEEE arithmetic) at run time. If you specify the `-fpe[:]3` compiler option, all floating-point exceptions are disabled, allowing IEEE exceptional values and program continuation. In contrast, specifying `-fpe[:]0` stops execution when an exceptional value (such as a NaN) is generated, when floating overflow or divide by zero occur, or when attempting to use a subnormal number, which usually allows you to localize the cause of the error. It also forces underflow to zero.
- The `warn` and `nowarn` options control compile-time warning messages, which, in some circumstances, can help determine the cause of a run-time error.
- On Linux* and on macOS*, the `-fexceptions` option enables C++ exception handling table generation, preventing Fortran routines in mixed-language applications from interfering with exception handling between C++ routines.
- On Windows*, the Compilation Diagnostics Options in the IDE control compile-time diagnostic messages, which, in some circumstances can help determine the cause of a run-time error.

Understanding Run-Time Errors
Traceback

List of Run-Time Error Messages

This section lists the errors processed by the compiler run-time library (RTL). For each error, the table provides the error number, the severity code, error message text, condition symbol name, and a detailed description of the error.

To define the condition symbol values (PARAMETER statements) in your program, include the following file:

```
for_iosdef.for
```

As described in the table, the severity of the message determines which of the following occurs:

- with *info* and *warning*, program execution continues
- with *error*, the results may be incorrect
- with *severe*, program execution stops (unless a recovery method is specified)

In the last case, to prevent program termination, you must include either an appropriate I/O error-handling specifier and recompile or, for certain errors, change the default action of a signal before you run the program again.

In the following table, the first column lists error numbers returned to IOSTAT variables when an I/O error is detected.

The first line of the second column provides the message as it is displayed (following *forrtl:*), including the severity level, message number, and the message text. The following lines of the second column contain the status condition symbol (such as FOR$IOS_INCRECTYP) and an explanation of the message.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
1[1]	**severe (1): Not a Fortran-specific error** FOR$IOS_NOTFORSPE. An error in the user program or in the RTL was not an Intel® Fortran-specific error and was not reportable through any other Intel® Fortran run-time messages.
8	**severe (8): Internal consistency check failure** FOR$IOS_BUG_CHECK. Internal error. Please check that the program is correct. Recompile if an error existed in the program. If this error persists, submit a problem report.
9	**severe (9): Permission to access file denied** FOR$IOS_PERACCFIL. Check the permissions of the specified file and whether the network device is mapped and available. Make sure the correct file and device was being accessed. Change the protection, specific file, or process used before rerunning the program.
10	**severe (10): Cannot overwrite existing file** FOR$IOS_CANOVEEXI. Specified file `xxx` already exists when OPEN statement specified STATUS='NEW' (create new file) using I/O unit *x*. Make sure correct file name, directory path, unit, and so forth were specified in the source program. Decide whether to: • Rename or remove the existing file before rerunning the program. • Modify the source file to specify different file specification, I/O unit, or OPEN statement STATUS.
11[1]	**info (11): Unit not connected** FOR$IOS_UNINOTCON. The specified unit was not open at the time of the attempted I/O operation. Check if correct unit number was specified. If appropriate, use an OPEN statement to explicitly open the file (connect the file to the unit number).
17	**severe (17): Syntax error in NAMELIST input** FOR$IOS_SYNERRNAM. The syntax of input to a namelist-directed READ statement was incorrect.
18	**severe (18): Too many values for NAMELIST variable** FOR$IOS_TOOMANVAL. An attempt was made to assign too many values to a variable during a namelist READ statement.
19	**severe (19): Invalid reference to variable in NAMELIST input** FOR$IOS_INVREFVAR. One of the following conditions occurred: • The variable was not a member of the namelist group. • An attempt was made to subscript a scalar variable. • A subscript of the array variable was out-of-bounds. • An array variable was specified with too many or too few subscripts for the variable.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	• An attempt was made to specify a substring of a non-character variable or array name. • A substring specifier of the character variable was out-of-bounds. • A subscript or substring specifier of the variable was not an integer constant. • An attempt was made to specify a substring by using an unsubscripted array variable.
20	**severe (20): REWIND error** FOR$IOS_REWERR. One of the following conditions occurred: • The file was not a sequential file. • The file was not opened for sequential or append access. • The Intel® Fortran RTL I/O system detected an error condition during execution of a REWIND statement.
21	**severe (21): Duplicate file specifications** FOR$IOS_DUPFILSPE. Multiple attempts were made to specify file attributes without an intervening close operation. A DEFINE FILE statement was followed by another DEFINE FILE statement or an OPEN statement.
22	**severe (22): Input record too long** FOR$IOS_INPRECTOO. A record was read that exceeded the explicit or default record length specified when the file was opened. To read the file, use an OPEN statement with a RECL=VALUE (record length) of the appropriate size.
23	**severe (23): BACKSPACE error** FOR$IOS_BACERR. The Intel® Fortran RTL I/O system detected an error condition during execution of a BACKSPACE statement.
24[1]	**severe (24): End-of-file during read** FOR$IOS_ENDDURREA. One of the following conditions occurred: • An Intel® Fortran RTL I/O system end-of-file condition was encountered during execution of a READ statement that did not contain an END, ERR, or IOSTAT specification. • An end-of-file record written by the ENDFILE statement was encountered during execution of a READ statement that did not contain an END, ERR, or IOSTAT specification. • An attempt was made to read past the end of an internal file character string or array during execution of a READ statement that did not contain an END, ERR, or IOSTAT specification. This error is returned by END and ERRSNS.
25	**severe (25): Record number outside range** FOR$IOS_RECNUMOUT. A direct access READ, WRITE, or FIND statement specified a record number outside the range specified when the file was opened.
26	**severe (26): OPEN or DEFINE FILE required** FOR$IOS_OPEDEFREQ. A direct access READ, WRITE, or FIND statement was attempted for a file when no prior DEFINE FILE or OPEN statement with ACCESS='DIRECT' was performed for that file.
27	**severe (27): Too many records in I/O statement** FOR$IOS_TOOMANREC. An attempt was made to do one of the following: • Read or write more than one record with an `ENCODE` or `DECODE` statement. • Write more records than existed.
28	**severe (28): CLOSE error**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_CLOERR. An error condition was detected by the Intel® Fortran RTL I/O system during execution of a CLOSE statement.
29	**severe (29): File not found** FOR$IOS_FILNOTFOU. A file with the specified name could not be found during an OPEN operation.
30	**severe (30): Open failure** FOR$IOS_OPEFAI. An error was detected by the Intel® Fortran RTL I/O system while attempting to open a file in an OPEN, INQUIRE, or other I/O statement. This message is issued when the error condition is not one of the more common conditions for which specific error messages are provided. It can occur when an OPEN operation was attempted for one of the following: • Segmented file that was not on a disk or a raw magnetic tape • Standard I/O file that had been closed
31	**severe (31): Mixed file access modes** FOR$IOS_MIXFILACC. An attempt was made to use any of the following combinations: • Formatted and unformatted operations on the same unit • An invalid combination of access modes on a unit, such as direct and sequential • An Intel® Fortran RTL I/O statement on a logical unit that was opened by a program coded in another language
32	**severe (32): Invalid logical unit number** FOR$IOS_INVLOGUNI. A logical unit number greater than 2,147,483,647 or less than zero was used in an I/O statement.
33	**severe (33): ENDFILE error** FOR$IOS_ENDFILERR. One of the following conditions occurred: • The file was not a sequential organization file with variable-length records. • The file was not opened for sequential, append, or direct access. • An unformatted file did not contain segmented records. • The Intel® Fortran RTL I/O system detected an error during execution of an ENDFILE statement.
34	**severe (34): Unit already open** FOR$IOS_UNIALROPE. A DEFINE FILE statement specified a logical unit that was already opened.
35	**severe (35): Segmented record format error** FOR$IOS_SEGRECFOR. An invalid segmented record control data word was detected in an unformatted sequential file. The file was probably either created with RECORDTYPE='FIXED' or 'VARIABLE' in effect, or was created by a program written in a language other than Fortran or Standard Fortran.
36	**severe (36): Attempt to access non-existent record** FOR$IOS_ATTACCNON. A direct-access READ or FIND statement attempted to access beyond the end of a relative file (or a sequential file on disk with fixed-length records) or access a record that was previously deleted from a relative file.
37	**severe (37): Inconsistent record length** FOR$IOS_INCRECLEN. An attempt was made to open a direct access file without specifying a record length.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
38	**severe (38): Error during write** FOR$IOS_ERRDURWRI. The Intel® Fortran RTL I/O system detected an error condition during execution of a WRITE statement.
39	**severe (39): Error during read** FOR$IOS_ERRDURREA. The Intel® Fortran RTL I/O system detected an error condition during execution of a READ statement.
40	**severe (40): Recursive I/O operation** FOR$IOS_RECIO_OPE. While processing an I/O statement for a logical unit, another I/O operation on the same logical unit was attempted, such as a function subprogram that performs I/O to the same logical unit that was referenced in an expression in an I/O list or variable format expression.
41	**severe (41): Insufficient virtual memory** FOR$IOS_INSVIRMEM. The Intel® Fortran RTL attempted to exceed its available virtual memory while dynamically allocating space. To overcome this problem, investigate increasing the data limit. Before you try to run this program again, wait until the new system resources take effect. **NOTE** This error can be returned by STAT in an ALLOCATE or a DEALLOCATE statement.
42	**severe (42): No such device** FOR$IOS_NO_SUCDEV. A pathname included an invalid or unknown device name when an OPEN operation was attempted.
43	**severe (43): File name specification error** FOR$IOS_FILNAMSPE. A pathname or file name given to an OPEN or INQUIRE statement was not acceptable to the Intel® Fortran RTL I/O system.
44	**severe (44): Inconsistent record type** FOR$IOS_INCRECTYP. The RECORDTYPE value in an OPEN statement did not match the record type attribute of the existing file that was opened.
45	**severe (45): Keyword value error in OPEN statement** FOR$IOS_KEYVALERR. An improper value was specified for an OPEN or CLOSE statement specifier requiring a value.
46	**severe (46): Inconsistent OPEN/CLOSE parameters** FOR$IOS_INCOPECLO. Specifications in an OPEN or CLOSE statement were inconsistent. Some invalid combinations follow: • READONLY or ACTION='READ' with STATUS='NEW' or STATUS='SCRATCH' • READONLY with STATUS='REPLACE', ACTION='WRITE', or ACTION='READWRITE' • ACCESS='APPEND' with READONLY, ACTION='READ', STATUS='NEW', or STATUS='SCRATCH' • DISPOSE='SAVE', 'PRINT', or 'SUBMIT' with STATUS='SCRATCH' • DISPOSE='DELETE' with READONLY • CLOSE statement STATUS='DELETE' with OPEN statement READONLY • ACCESS='DIRECT' with POSITION='APPEND' or 'ASIS'
47	**severe (47): Write to READONLY file**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_WRIREAFIL. A write operation was attempted to a file that was declared ACTION='READ' or READONLY in the OPEN statement that is currently in effect.
48	**severe (48): Invalid argument to Fortran Run-Time Library** FOR$IOS_INVARGFOR. The compiler passed an invalid or improperly coded argument to the Intel® Fortran RTL. This can occur if the compiler is newer than the RTL in use.
51	**severe (51): Inconsistent file organization** FOR$IOS_INCFILORG. The file organization specified in an OPEN statement did not match the organization of the existing file.
53	**severe (53): No current record** FOR$IOS_NO_CURREC. Attempted to execute a REWRITE statement to rewrite a record when the current record was undefined. To define the current record, execute a successful READ statement. You can optionally perform an INQUIRE statement on the logical unit after the READ statement and before the REWRITE statement. No other operations on the logical unit may be performed between the READ and REWRITE statements.
55	**severe (55): DELETE error** FOR$IOS_DELERR. An error condition was detected by the Intel® Fortran RTL I/O system during execution of a DELETE statement.
57	**severe (57): FIND error** FOR$IOS_FINERR. The Intel® Fortran RTL I/O system detected an error condition during execution of a FIND statement.
58[1]	**info (58): Format syntax error at or near xx** FOR$IOS_FMTSYN. Check the statement containing *xx*, a character substring from the format string, for a format syntax error. For more information, see the FORMAT statement.
59	**severe (59): List-directed I/O syntax error** FOR$IOS_LISIO_SYN. The data in a list-directed input record had an invalid format, or the type of the constant was incompatible with the corresponding variable. The value of the variable was unchanged. **NOTE** Note: The ERR transfer is taken after completion of the I/O statement for error number 59. The resulting file status and record position are the same as if no error had occurred. However, other I/O errors take the ERR transfer as soon as the error is detected, so file status and record position are undefined.
60	**severe (60): Infinite format loop** FOR$IOS_INFFORLOO. The format associated with an I/O statement that included an I/O list had no field descriptors to use in transferring those values.
61	**severe or info(61): Format/variable-type mismatch** FOR$IOS_FORVARMIS. An attempt was made either to read or write a real variable with an integer field descriptor (I, L, O, Z, B), or to read or write an integer or logical variable with a real field descriptor (D, E, or F). To suppress this error message, see the description of `check[:]noformat`.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation

NOTE
Note: The severity depends on the `check[:]keywords` option used during the compilation command. The ERR transfer is taken after completion of the I/O statement for error numbers 61, 63, 64, and 68. The resulting file status and record position are the same as if no error had occurred. However, other I/O errors take the ERR transfer as soon as the error is detected, so file status and record position are undefined.

62 **severe (62): Syntax error in format**

FOR$IOS_SYNERRFOR. A syntax error was encountered while the RTL was processing a format stored in an array or character variable.

63 **error or info(63): Output conversion error**

FOR$IOS_OUTCONERR. During a formatted output operation, the value of a particular number could not be output in the specified field length without loss of significant digits. When this situation is encountered, the overflowed field is filled with asterisks to indicate the error in the output record. If no ERR address has been defined for this error, the program continues after the error message is displayed. To suppress this error message, see the description of `check[:]nooutput_conversion`.

NOTE
Note: The severity depends on the `check[:]keywords` option used during the compilation command. The ERR transfer is taken after completion of the I/O statement for error numbers 61, 63, 64, and 68. The resulting file status and record position are the same as if no error had occurred. However, other I/O errors take the ERR transfer as soon as the error is detected, so file status and record position are undefined.

64 **severe (64): Input conversion error**

FOR$IOS_INPCONERR. During a formatted input operation, an invalid character was detected in an input field, or the input value overflowed the range representable in the input variable. The value of the variable was set to zero.

NOTE
The ERR transfer is taken after completion of the I/O statement for error numbers 61, 63, 64, and 68. The resulting file status and record position are the same as if no error had occurred. However, other I/O errors take the ERR transfer as soon as the error is detected, so file status and record position are undefined.

65 **error (65): Floating invalid**

FOR$IOS_FLTINV. During an arithmetic operation, the floating-point values used in a calculation were invalid for the type of operation requested or invalid exceptional values. For example, the error can occur if you request a log of the floating-point values 0.0 or a negative number. For certain arithmetic expressions, specifying the `check[:]nopower` option can suppress this message.

66 **severe (66): Output statement overflows record**

FOR$IOS_OUTSTAOVE. An output statement attempted to transfer more data than would fit in the maximum record size.

67 **severe (67): Input statement requires too much data**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_INPSTAREQ. Attempted to read more data than exists in a record with an unformatted READ statement or with a formatted sequential READ statement from a file opened with a PAD='NO' specifier.
68	**severe (68): Variable format expression value error** FOR$IOS_VFEVALERR. The value of a variable format expression was not within the range acceptable for its intended use; for example, a field width was less than or equal to zero. A value of 1 was assumed, except for a P edit descriptor, for which a value of zero was assumed.
	NOTE The ERR transfer is taken after completion of the I/O statement for error numbers 61, 63, 64, and 68. The resulting file status and record position are the same as if no error had occurred. However, other I/O errors take the ERR transfer as soon as the error is detected, so file status and record position are undefined.
69[1]	**error (69): Process interrupted (SIGINT)** FOR$IOS_SIGINT. The process received the signal SIGINT. Determine source of this interrupt signal (described in signal(3)).
72[1]	**error (72): Floating overflow** FOR$IOS_FLTOVF. During an arithmetic operation, a floating-point value exceeded the largest representable value for that data type. See Data Representation for ranges of the various data types.
73[1]	**error (73): Floating divide by zero** FOR$IOS_FLTDIV. During a floating-point arithmetic operation, an attempt was made to divide by zero.
74[1]	**error (74): Floating underflow** FOR$IOS_FLTUND. During an arithmetic operation, a floating-point value became less than the smallest finite value for that data type. Depending on the values of the `fpe[:]`*n* option, the underflowed result was either set to zero or allowed to gradually underflow. See the Data Representation for ranges of the various data types.
75[1]	**error (75): Floating point exception** FOR$IOS_SIGFPE. A floating-point exception occurred. Possible causes include: • Division by zero. • Overflow. • An invalid operation, such as subtraction of infinite values, multiplication of zero by infinity without signs), division of zero by zero or infinity by infinity. • Conversion of floating-point to fixed-point format when an overflow prevents conversion.
76[1]	**error (76): IOT trap signal** FOR$IOS_SIGIOT. Core dump file created. Examine core dump for possible cause of this `IOT` signal.
77[1]	**severe (77): Subscript out of range** FOR$IOS_SUBRNG. An array reference was detected outside the declared array bounds.
78[1]	**error (78): Process killed** FOR$IOS_SIGTERM. The process received a signal requesting termination of this process. Determine the source of this software termination signal.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
79[1]	**error (79): Process quit** FOR$IOS_SIGQUIT. The process received a signal requesting termination of itself. Determine the source of this quit signal.
90[1]	**info (90): INQUIRE of internal unit-number is always an error (NOTE: unit identifies a file)** FOR$IOS_IOSTAT_INTERNAL. The file name specified for an INQUIRE statement is an internal unit-number.
91[1]	**info (91): INQUIRE of internal unit-number is always an error (NOTE: unit does not identify a file)** FOR$IOS_IOSTAT_INTERNAL_UNIT. The unit number specified for an INQUIRE statement is an internal unit-number.
95[1]	**info (95): Floating-point conversion failed** FOR$IOS_FLOCONFAI. The attempted unformatted read or write of nonnative floating-point data failed because the floating-point value: • Exceeded the allowable maximum value for the equivalent native format and was set equal to infinity (plus or minus). • Was infinity (plus or minus) and was set to infinity (plus or minus). • Was invalid and was set to not a number (NaN). Very small numbers are set to zero (0). This error could be caused by the specified nonnative floating-point format not matching the floating-point format found in the specified file. Check the following: • The correct file was specified. • The record layout matches the format Intel® Fortran is expecting. • The ranges for the data being used (see Data Representation). • The correct nonnative floating-point data format was specified (see Supported Native and Nonnative Numeric Formats).
96	**info (96): F_UFMTENDIAN environment variable was ignored:erroneous syntax** FOR$IOS_UFMTENDIAN. Syntax for specifying whether little endian or big endian conversion is performed for a given Fortran unit was incorrect. Even though the program will run, the results might not be correct if you do not change the value of `F_UFMTENDIAN`. For correct syntax, see Environment Variable F_UFMTENDIAN Method.
98	**Severe (98): cannot allocate memory for the file buffer - out of memory** FOR_S_NOMEMFORIO. This error often occurs during a file I-O operation such as OPEN, READ, or WRITE. Either increase the amount of memory available to the program, or reduce its demand.
104	**Severe (104): incorrect "XXXXX=" specifier value for connected file** FOR$IOS_BADSPECVAL. The listed specifier value is invalid for the connected file. Possible specifier values are one of the following: • ACTION= • ASSOCIATEVARIABLE= • ASYNCHRONOUS= • BUFFERED= • DISPOSE= • FORM= • IOFOCUS= • MAXREC=

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	• MODE= • ORGANIZATION= • POSITION= • RECL= • RECORDTYPE= • SHARE= • STATUS= • TITLE=
106	**Severe (106): FORT_BLOCKSIZE environment variable has erroneous syntax** FOR_S_INVBLOCKSIZE. Syntax for specifying the default block size value was incorrect. For correct syntax, see Environment Variable `FORT_BLOCKSIZE`.
107	**Severe (107): FORT_BUFFERCOUNT environment variable has erroneous syntax** FOR_S_INVBUFRCNT. Syntax for specifying the default buffer count value was incorrect. For correct syntax, see Environment Variable `FORT_BUFFERCOUNT`.
108	**Severe (108): Cannot stat file** FOR$IOS_CANSTAFILE. Make sure correct file and unit were specified.
109	**info (109): stream data transfer statement is not allowed to an unopened unit** FOR$IOS_SIONOTOPEN. Stream data transfer statement is not allowed to an unopened unit.
118	**severe (118): The 'RECL=' value in an OPEN statement exceeds the maximum allowed for the file's record type.** FOR$IOS_MAX_FXD_RECL. The 'RECL=' value in an OPEN statement is too large for the file's record type.
119[1]	**severe (119): The FORT_BUFFERING_THRESHOLD environment variable has erroneous syntax** FOR$ IOS_INVTHRESHOLD. If specified, the FORT_BUFFERING_THRESHOLD environment variable must be an integer value greater than zero and less than 2147483647.
120	**severe (120): Operation requires seek ability** FOR$IOS_OPEREQSEE. Attempted an operation on a file that requires the ability to perform seek operations on that file. Make sure the correct unit, directory path, and file were specified.
121	**Severe (121): Cannot access current working directory** FOR$IOS_CWDERROR. Cannot access the current working directory to open or access a file. One of the following conditions occurred: • The directory has been deleted or moved by another task. • The getcwd system function failed due to an OS or file-system problem.
122	**Severe (122): invalid attempt to assign into a pointer that is not associated** FOR$IOS_UNASSOCPTR. Invalid attempt to assign into a pointer that is not associated.
124[1]	**severe (124): Invalid command supplied to EXECUTE_COMMAND_LINE** FOR$ IOS_INVCMDECL. The command line passed to the EXECUTE_COMMAND_LINE intrinsic is invalid.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation

NOTE
This error can be returned by CMDSTAT in an EXECUTE_COMMAND_LINE statement.

127 **Severe (127): User Defined I/O procedure returned error <user-iostat, message: '<user-iomsg>'**

FOR$IOS_UDIO_CHILD_IOSTAT_IOMSG. A child I/O action has set the IOMSG and IOSTAT shown in this message.

128 **info (128): Error stop – program terminated**

FOR$IOS_ERROR_STOP. The user program has executed an ERROR STOP statement.

129 **info (129): User Defined I/O procedure's IOMSG was truncated to fit IOMSG variable**

FOR$IOS_UDIO_IOMSG_TRUNCATED. A child I/O action has set IOMSG and IOSTAT. The result was too large to be held by the parent's IOMSG variable; non-blank text has been truncated.

134 **No associated message**

The program was terminated internally through abort().

138[1] **severe (138): Array index out of bounds**

FOR$IOS_BRK_RANGE. An array subscript is outside the dimensioned boundaries of that array. Set the `check[:]bounds` option and recompile.

139[1] **severe: (139): Array index out of bounds for index nn**

FOR$IOS_BRK_RANGE2. An array subscript is outside the dimensioned boundaries of that array. Set the `check[:]bounds` option and recompile.

140[1] **error (140): Floating inexact**

FOR$IOS_FLTINE. A floating-point arithmetic or conversion operation gave a result that differs from the mathematically exact result. This trap is reported if the rounded result of an IEEE operation is not exact.

144[1] **severe (144): Reserved operand**

FOR$IOS_ROPRAND. The Intel® Fortran RTL encountered a reserved operand while executing your program. Please report the problem to Intel.

145[1] **severe (145): Assertion error**

FOR$IOS_ASSERTERR. The Intel® Fortran RTL encountered an assertion error. Please report the problem to Intel.

146[1] **severe (146): Null pointer error**

FOR$IOS_NULPTRERR. Attempted to use a pointer that does not contain an address. Modify the source program, recompile, and relink.

147[1] **severe (147): Stack overflow**

FOR$IOS_STKOVF. The Intel® Fortran RTL encountered a stack overflow while executing your program.

148[1] **severe (148): String length error**

FOR$IOS_STRLENERR. During a string operation, an integer value appears in a context where the value of the integer is outside the permissible string length range. Set the `check[:]bounds` option and recompile.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
149[1]	**severe (149): Substring error** FOR$IOS_SUBSTRERR. An array subscript is outside the dimensioned boundaries of an array. Set the `check[:]bounds` option and recompile.
150[1]	**severe (150): Range error** FOR$IOS_RANGEERR. An integer value appears in a context where the value of the integer is outside the permissible range.
151[1]	**severe (151): Allocatable array is already allocated** FOR$IOS_INVREALLOC. An allocatable array must not already be allocated when you attempt to allocate it. You must deallocate the array before it can again be allocated. **NOTE** This error can be returned by STAT in an ALLOCATE statement.
152[1]	**severe (152): Unresolved contention for Intel Fortran RTL global resource** FOR$IOS_RESACQFAI. Failed to acquire an Intel® Fortran RTL global resource for a reentrant routine. For a multithreaded program, the requested global resource is held by a different thread in your program. For a program using asynchronous handlers, the requested global resource is held by the calling part of the program (such as main program) and your asynchronous handler attempted to acquire the same global resource.
153[1]	**severe (153): Allocatable array or pointer is not allocated** FOR$IOS_INVDEALLOC. A Standard Fortran allocatable array or pointer must already be allocated when you attempt to deallocate it. You must allocate the array or pointer before it can again be deallocated. **NOTE** This error can be returned by STAT in an DEALLOCATE statement.
154[1]	**severe(154): Array index out of bounds** FOR$IOS_RANGE. An array subscript is outside the dimensioned boundaries of that array. Set the `check[:]bounds` option and recompile.
155[1]	**severe(155): Array index out of bounds for index nn** FOR$IOS_RANGE2. An array subscript is outside the dimensioned boundaries of that array. Set the `check[:]bounds` option and recompile.
156[1]	**severe(156): GENTRAP code = hex dec** FOR$IOS_DEF_GENTRAP. The Intel® Fortran RTL has detected an unknown `GENTRAP` code. The cause is most likely a software problem due to memory corruption, or software signaling an exception with an incorrect exception code. Try setting the `check[:]bounds` option and recompile to see if that finds the problem.
157[1]	**severe(157): Program Exception - access violation** FOR$IOS_ACCVIO. The program tried to read from or write to a virtual address for which it does not have the appropriate access. Try setting the `check[:]bounds` option and recompile to see if the problem is an out-of-bounds memory reference or a argument mismatch that causes data to be treated as an address.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	Other possible causes of this error include: • Mismatches in C vs. STDCALL calling mechanisms, causing the stack to become corrupted. • References to unallocated pointers. • Attempting to access a protected (for example, read-only) address.
158[1]	**severe(158): Program Exception - datatype misalignment** FOR$IOS_DTYPE_MISALIGN. The Intel® Fortran RTL has detected data that is not aligned on a natural boundary for the data type specified. For example, a REAL(8) data item aligned on natural boundaries has an address that is a multiple of 8. To ensure naturally aligned data, use the `align` option. This is an operating system error. See your operating system documentation for more information.
159[1]	**severe(159): Program Exception - breakpoint** FOR$IOS_PGM_BPT. The Intel® Fortran RTL has encountered a breakpoint in the program. This is an operating system error. See your operating system documentation for more information.
160[1]	**severe(160): Program Exception - single step** FOR$IOS_PGM_SS. A trace trap or other single-instruction mechanism has signaled that one instruction has been executed. This is an operating system error. See your operating system documentation for more information.
161[1]	**severe(161): Program Exception - array bounds exceeded** FOR$IOS_PGM_BOUNDS. The program tried to access an array element that is outside the specified boundaries of the array. Set the `check[:]bounds` option and recompile.
162[1]	**severe(162): Program Exception - denormal floating-point operand** FOR$IOS_PGM_DENORM. A floating-point arithmetic or conversion operation has a subnormalized number as an operand. A subnormalized number is smaller than the lowest value in the normal range for the data type specified. See Data Representation for ranges for floating-point types. Either locate and correct the source code causing the subnormalized value or, if a subnormalized value is acceptable, specify a different value for the `fpe` compiler option to allow program continuation.
163[1]	**severe(163): Program Exception - floating stack check** FOR$IOS_PGM_FLTSTK. During a floating-point operation, the floating-point register stack on systems using IA-32 architecture overflowed or underflowed. This is a fatal exception. The most likely cause is calling a REAL function as if it were an INTEGER function or subroutine, or calling an INTEGER function or subroutine as if it were a REAL function. Carefully check that the calling code and routine being called agree as to how the routine is declared. If you are unable to resolve the issue, please send a problem report with an example to Intel.
164[1]	**severe(164): Program Exception - integer divide by zero** FOR$IOS_PGM_INTDIV. During an integer arithmetic operation, an attempt was made to divide by zero. Locate and correct the source code causing the integer divide by zero.
166[1]	**severe(166): Program Exception - privileged instruction**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_PGM_PRIVINST. The program tried to execute an instruction whose operation is not allowed in the current machine mode. This is an operating system error. See your operating system documentation for more information.
167[1]	**severe(167): Program Exception - in page error** FOR$IOS_PGM_INPGERR. The program tried to access a page that was not present, so the system was unable to load the page. For example, this error might occur if a network connection was lost while trying to run a program over the network. This is an operating system error. See your operating system documentation for more information.
168[1]	**severe(168): Program Exception - illegal instruction** FOR$IOS_PGM_ILLINST. The program tried to execute an invalid instruction. This is an operating system error. See your operating system documentation for more information.
169[1]	**severe(169): Program Exception - noncontinuable exception** FOR$IOS_PGM_NOCONTEXCP. The program tried to continue execution after a noncontinuable exception occurred. This is an operating system error. See your operating system documentation for more information.
170[1]	**severe(170): Program Exception - stack overflow** FOR$IOS_PGM_STKOVF. The Intel® Fortran RTL has detected a stack overflow while executing your program. See your Release Notes for information on how to increase stack size.
171[1]	**severe(171): Program Exception - invalid disposition** FOR$IOS_PGM_INVDISP. An exception handler returned an invalid disposition to the exception dispatcher. Programmers using a high-level language should never encounter this exception. This is an operating system error. See your operating system documentation for more information.
172[1]	**severe(172): Program Exception - exception code = hex dec** FOR$IOS_PGM_EXCP_CODE. The Intel® Fortran RTL has detected an unknown exception code. This is an operating system error. See your operating system documentation for more information.
173[1]	**severe(173): A pointer passed to DEALLOCATE points to an array that cannot be deallocated** FOR$IOS_INVDEALLOC2. A pointer that was passed to DEALLOCATE pointed to an explicit array, an array slice, or some other type of memory that could not be deallocated in a DEALLOCATE statement. Only whole arrays previous allocated with an ALLOCATE statement may be validly passed to DEALLOCATE. **NOTE** This error can be returned by STAT in a DEALLOCATE statement.
174[1]	**severe (174): SIGSEGV, message-text** FOR$IOS_SIGSEGV. One of two possible messages occurs for this error number:

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation

```
severe (174): SIGSEGV, segmentation fault occurred
```

This message indicates that the program attempted an invalid memory reference. Check the program for possible errors.

```
severe (174): SIGSEGV, possible program stack overflow occurred
```

The following explanatory text also appears:

```
Program requirements exceed current stacksize resource limit.
```

175[1] **severe(175): DATE argument to DATE_AND_TIME is too short (LEN=n), required LEN=8**

FOR$IOS_SHORTDATEARG. The number of characters associated with the DATE argument to the DATE_AND_TIME intrinsic was shorter than the required length. You must increase the number of characters passed in for this argument to be at least eight characters in length. Verify that the TIME and ZONE arguments also meet their minimum lengths.

176[1] **severe(176): TIME argument to DATE_AND_TIME is too short (LEN=n), required LEN=10**

FOR$IOS_SHORTTIMEARG. The number of characters associated with the TIME argument to the DATE_AND_TIME intrinsic was shorter than the required length. You must increase the number of characters passed in for this argument to be at least ten characters in length. Verify that the DATE and ZONE arguments also meet their minimum lengths.

177[1] **severe(177): ZONE argument to DATE_AND_TIME is too short (LEN=n), required LEN=5**

FOR$IOS_SHORTZONEARG. The number of characters associated with the ZONE argument to the DATE_AND_TIME intrinsic was shorter than the required length. You must increase the number of characters passed in for this argument to be at least five characters in length. Verify that the DATE and TIME arguments also meet their minimum lengths.

178[1] **severe(178): Divide by zero**

FOR$IOS_DIV. A floating-point or integer divide-by-zero exception occurred.

179[1] **severe(179): Cannot allocate array - overflow on array size calculation**

FOR$IOS_ARRSIZEOVF. An attempt to dynamically allocate storage for an array failed because the required storage size exceeds addressable memory.

NOTE
This error can be returned by STAT in an ALLOCATE statement.

182[1] **severe (182): floating invalid - possible uninitialized real/complex variable.**

FOR$ IOS_FLTINV_UNINIT. An invalid floating-point operation failed invalid – likely caused by an uninitialized real/complex variable.

183 **warning (183): FASTMEM allocation is requested but the libmemkind library is not linked in, so using the default allocator.**

FOR$IOS_NOLIBMEMKINDWARN. An allocation requested FASTMEM but the libmemkind library is not linked into the executable, so memory will be allocated from the default memory allocator for that platform.

184 **severe (184): FASTMEM allocation is requested but the libmemkind library is not linked into the executable.**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation

FOR$IOS_NOLIBMEMKINDWARN. An allocation request for FASTMEM failed because the libmemkind library is not linked into the executable.

NOTE
This error can be returned by STAT in an ALLOCATE statement.

185 **warning (185): FASTMEM allocation is requested but HBW memory is not available, so using the default allocator.**

FOR$IOS_NOFASTMEMWARN. An allocation requested FASTMEM but HBW memory is not available on the node, so memory will be allocated from the default memory allocator for that platform.

186 **severe (186): FASTMEM allocation is requested but HBW memory is not available on this node.**

FOR$IOS_NOLIBMEMKINDWARN. An allocation request for FASTMEM failed because HBW memory is not available on this node.

NOTE
This error can be returned by STAT in an ALLOCATE statement.

188 **severe (188): An assignment was made from an object of one size to an object of a different size that cannot be deallocated.**

FOR$ IOS_INCOMPATIBLE_SIZES. An assignment was made from an object of one size to an object of a different size that cannot be deallocated.

NOTE
This error can be returned by STAT in an ALLOCATE statement.

189 **severe (189): LHS and RHS of an assignment statement have incompatible types.**

FOR$ IOS_INCOMPATIBLE_TYPES. The left-hand side (LHS) of an assignment statement is not type compatible with the right-hand side (RHS) of the assignment statement.

NOTE
This error can be returned by STAT in an ALLOCATE statement.

190 **severe (190): For allocate(source=), source needs to be allocated.**

FOR$ IOS_ALLOC_INVSOURCE. For allocate(source=), if source is a pointer then it should be associated with a target. If it is allocatable, it should be allocated.

NOTE
This error can be returned by STAT in an ALLOCATE statement.

194[1] **severe (194): Run-Time Check Failure. The variable \'%s\' is being used in \'%s\' without being defined.**

FOR$ IOS_RTC_UNINIT_USE_SRC. The named variable in the named source file is being used without first being initialized.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
256	**severe (256): Unformatted I/O to unit open for formatted transfers** FOR$IOS_UNFIO_FMT. Attempted unformatted I/O to a unit where the OPEN statement (FORM specifier) indicated the file was formatted. Check that the correct unit (file) was specified. If the FORM specifier was not present in the OPEN statement and the file contains unformatted data, specify FORM='UNFORMATTED' in the OPEN statement. Otherwise, if appropriate, use formatted I/O (such as list-directed or namelist I/O).
257	**severe (257): Formatted I/O to unit open for unformatted transfers** FOR$IOS_FMTIO_UNF. Attempted formatted I/O (such as list-directed or namelist I/O) to a unit where the OPEN statement indicated the file was unformatted (FORM specifier). Check that the correct unit (file) was specified. If the FORM specifier was not present in the OPEN statement and the file contains formatted data, specify FORM='FORMATTED' in the OPEN statement. Otherwise, if appropriate, use unformatted I/O.
259	**severe (259): Sequential-access I/O to unit open for direct access** FOR$IOS_SEQIO_DIR. The OPEN statement for this unit number specified direct access and the I/O statement specifies sequential access. Check the OPEN statement and make sure the I/O statement uses the correct unit number and type of access.
264	**severe (264): operation requires file to be on disk or tape** FOR$IOS_OPEREQDIS. Attempted to use a BACKSPACE statement on such devices as a terminal.
265	**severe (265): operation requires sequential file organization and access** FOR$IOS_OPEREQSEQ. Attempted to use a BACKSPACE statement on a file whose organization was not sequential or whose access was not sequential. A BACKSPACE statement can only be used for sequential files opened for sequential access.
266[1]	**error (266): Fortran abort routine called** FOR$IOS_PROABOUSE. The program called the abort routine to terminate itself.
268[1]	**severe (268): End of record during read** FOR$IOS_ENDRECDUR. An end-of-record condition was encountered during execution of a non-advancing I/O READ statement that did not specify the EOR branch specifier.
296[1]	**info(296): nn floating inexact traps** FOR$IOS_FLOINEEXC. The total number of floating-point inexact data traps encountered during program execution was *nn*. This summary message appears at program completion.
297[1]	**info (297): nn floating invalid traps** FOR$IOS_FLOINVEXC. The total number of floating-point invalid data traps encountered during program execution was *nn*. This summary message appears at program completion.
298[1]	**info (298): nn floating overflow traps** FOR$IOS_FLOOVFEXC. The total number of floating-point overflow traps encountered during program execution was *nn*. This summary message appears at program completion.
299[1]	**info (299): nn floating divide-by-zero traps** FOR$IOS_FLODIV0EXC. The total number of floating-point divide-by-zero traps encountered during program execution was *nn*. This summary message appears at program completion.
300[1]	**info (300): nn floating underflow traps** FOR$IOS_FLOUNDEXC. The total number of floating-point underflow traps encountered during program execution was *nn*. This summary message appears at program completion.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
408	**Severe (408): fort: (19): Dummy character variable \'%s\' has length 1 which is greater then actual variable length**
529	**Info (529): Attempt to close a unit which was not open.** FOR$IOS_SYNERRNAM. The unit number specified on a CLOSE statement is not currently open.
540	**severe (540): Array or substring subscript expression out of range** FOR$IOS_F6096. An expression used to index an array was smaller than the lower dimension bound or larger than the upper dimension bound.
541	**severe (541): CHARACTER substring expression out of range** FOR$IOS_F6097. An expression used to index a character substring was illegal.
542	**severe (542): Label not found in assigned GOTO list** FOR$IOS_F6098. The label assigned to the integer-variable name was not specified in the label list of the assigned GOTO statement.
545	**severe (545): Invalid INTEGER** FOR$IOS_F6101. Either an illegal character appeared as part of an integer, or a numeric character larger than the radix was used in an alternate radix specifier.
546	**severe (546): REAL indefinite (uninitialized or previous error)** FOR$IOS_F6102. An invalid real number was read from a file, an internal variable, or the console. This can happen if an invalid number is generated by passing an illegal argument to an intrinsic function -- for example, SQRT(-1) or ASIN(2). If the invalid result is written and then later read, the error will be generated.
547	**severe (547): Invalid REAL** FOR$IOS_F103. An illegal character appeared as part of a real number.
548	**severe (548): REAL math overflow** FOR$IOS_F6104. A real value was too large. Floating-point overflows in either direct or emulated mode generate NaN (Not-A-Number) exceptions, which appear in the output field as asterisks (*) or the letters NAN.
551	**severe (551): Formatted I/O not consistent with OPEN options** FOR$IOS_F6200. The program tried to perform formatted I/O on a unit opened with FORM='UNFORMATTED' or FORM='BINARY'.
552	**severe (552): List-directed I/O not consistent with OPEN options** FOR$IOS_F6201. The program tried to perform list-directed I/O on a file that was not opened with FORM='FORMATTED' and ACCESS='SEQUENTIAL'.
553	**severe (553): Terminal I/O not consistent with OPEN options** FOR$IOS_F6202. When a special device such as CON, LPT1, or PRN is opened in an OPEN statement, its access must be sequential and its format must be either formatted or binary. By default ACCESS='SEQUENTIAL' and FORM='FORMATTED' in OPEN statements. To generate this error the device's OPEN statement must contain an option not appropriate for a terminal device, such as ACCESS='DIRECT' or FORM='UNFORMATTED'.
554	**severe (554): Direct I/O not consistent with OPEN options** FOR$IOS_F6203. A REC=*option* was included in a statement that transferred data to a file that was opened with the ACCESS='SEQUENTIAL' option.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
555	**severe (555): Unformatted I/O not consistent with OPEN options** FOR$IOS_F6204. If a file is opened with FORM='FORMATTED', unformatted or binary data transfer is prohibited.
556	**severe (556): A edit descriptor expected for CHARACTER** FOR$IOS_F6205. The A edit descriptor was not specified when a character data item was read or written using formatted I/O.
557	**severe (557): E, F, D, or G edit descriptor expected for REAL** FOR$IOS_F6206. The E, F, D, or G edit descriptor was not specified when a real data item was read or written using formatted I/O.
558	**severe (558): I edit descriptor expected for INTEGER** FOR$IOS_F6207. The I edit descriptor was not specified when an integer data item was read or written using formatted I/O.
559	**severe (559): L edit descriptor expected for LOGICAL** FOR$IOS_F6208. The L edit descriptor was not specified when a logical data item was read or written using formatted I/O.
560	**severe (560): File already open: parameter mismatch** FOR$IOS_F6209. An OPEN statement specified a connection between a unit and a filename that was already in effect. In this case, only the BLANK= specifier can have a different setting.
561	**severe (561): Namelist I/O not consistent with OPEN options** FOR$IOS_F6210. The program tried to perform namelist I/O on a file that was not opened with FORM='FORMATTED' and ACCESS='SEQUENTIAL'.
562	**severe (562): IOFOCUS option illegal with non-window unit** FOR$IOS_F6211. IOFOCUS was specified in an OPEN or INQUIRE statement for a non-window unit. The IOFOCUS option can only be used when the unit opened or inquired about is a QuickWin child window.
563	**severe (563): IOFOCUS option illegal without QuickWin** FOR$IOS_F6212. IOFOCUS was specified in an OPEN or INQUIRE statement for a non-QuickWin application. The IOFOCUS option can only be used when the unit opened or inquired about is a QuickWin child window.
564	**severe (564): TITLE illegal with non-window unit** FOR$IOS_F6213. TITLE was specified in an OPEN or INQUIRE statement for a non-window unit. The TITLE option can only be used when the unit opened or inquired about is a QuickWin child window.
565	**severe (565): TITLE illegal without QuickWin** FOR$IOS_F6214. TITLE was specified in an OPEN or INQUIRE statement for a non-QuickWin application. The TITLE option can only be used when the unit opened or inquired about is a QuickWin child window.
566	**severe (566): KEEP illegal for scratch file** FOR$IOS_F6300. STATUS='KEEP' was specified for a scratch file. This is illegal because scratch files are automatically deleted at program termination.
567	**severe (567): SCRATCH illegal for named file**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6301. STATUS='SCRATCH' should not be used in a statement that includes a filename.
568	**severe (568): Multiple radix specifiers** FOR$IOS_F6302. More than one alternate radix for numeric I/O was specified. F6302 can indicate an error in spacing or a mismatched format for data of different radices.
569	**severe (569): Illegal radix specifier** FOR$IOS_F6303. A radix specifier was not between 2 and 36, inclusive. Alternate radix constants must be of the form n#ddd... where n is a radix from 2 to 36 inclusive and ddd... are digits with values less than the radix. For example, 3#12 and 34#7AX are valid constants with valid radix specifiers. 245#7A and 39#12 do not have valid radix specifiers and generate error 569 if input.
570	**severe (570): Illegal STATUS value** FOR$IOS_F6304. An illegal value was used with the STATUS option. STATUS accepts the following values: • 'KEEP' or 'DELETE'' when used with CLOSE statements • 'OLD', 'NEW', 'SCRATCH', or 'UNKNOWN' when used with OPEN statements
571	**severe (571): Illegal MODE value** FOR$IOS_F6305. An illegal value was used with the MODE option. MODE accepts the values 'READ', 'WRITE', or 'READWRITE'.
572	**severe (572): Illegal ACCESS value** FOR$IOS_F6306. An illegal value was used with the ACCESS option. ACCESS accepts the values 'SEQUENTIAL' and 'DIRECT'.
573	**severe (573): Illegal BLANK value** FOR$IOS_F6307. An illegal value was used with the BLANK option. BLANK accepts the values 'NULL' and 'ZERO'.
574	**severe (574): Illegal FORM value** FOR$IOS_F6308. An illegal value was used with the FORM option. FORM accepts the following values: 'FORMATTED', 'UNFORMATTED', and 'BINARY'.
575	**severe (575): Illegal SHARE value** FOR$IOS_F6309. An illegal value was used with the SHARE option. SHARE accepts the values 'COMPAT', 'DENYRW', 'DENYWR', 'DENYRD', and 'DENYNONE'.
577	**severe (577): Illegal record number** FOR$IOS_F6311. An invalid number was specified as the record number for a direct-access file. The first valid record number for direct-access files is 1.
578	**severe (578): No unit number associated with *** FOR$IOS_F6312. In an INQUIRE statement, the NUMBER option was specified for the file associated with * (console).
580	**severe (580): Illegal unit number** FOR$IOS_F6314. An illegal unit number was specified.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	Legal unit numbers can range from 0 through 2**31-1, inclusive.
581	**severe (581): Illegal RECL value** FOR$IOS_F6315. A negative or zero record length was specified for a direct file. The smallest valid record length for direct files is 1.
582	**severe (582): Array already allocated** FOR$IOS_F6316. The program attempted to ALLOCATE an already allocated array.
583	**severe (583): Array size zero or negative** FOR$IOS_F6317. The size specified for an array in an ALLOCATE statement must be greater than zero.
584	**severe (584): Non-HUGE array exceeds 64K** FOR$IOS_F6318.
585	**severe (585): Array not allocated** FOR$IOS_F6319. The program attempted to DEALLOCATE an array that was never allocated.
586	**severe (586): BACKSPACE illegal on terminal device** FOR$IOS_F6400. A BACKSPACE statement specified a unit connected to a terminal device such as a terminal or printer.
587	**severe (587): EOF illegal on terminal device** FOR$IOS_F6401. An EOF intrinsic function specified a unit connected to a terminal device such as a terminal or printer.
588	**severe (588): ENDFILE illegal on terminal device** FOR$IOS_F6402. An ENDFILE statement specified a unit connected to a terminal device such as a terminal or printer.
589	**severe (589): REWIND illegal on terminal device** FOR$IOS_F6403. A REWIND statement specified a unit connected to a terminal device such as a terminal or printer.
590	**severe (590): DELETE illegal for read-only file** FOR$IOS_F6404. A CLOSE statement specified STATUS='DELETE' for a read-only file.
591	**severe (591): External I/O illegal beyond end of file** FOR$IOS_F6405. The program tried to access a file after executing an ENDFILE statement or after it encountered the end-of-file record during a read operation. A BACKSPACE, REWIND, or OPEN statement must be used to reposition the file before execution of any I/O statement that transfers data.
592	**severe (592): Truncation error: file closed** FOR$IOS_F6406.
593	**severe (593): Terminal buffer overflow** FOR$IOS_F6407. More than 131 characters were input to a record of a unit connected to the terminal (keyboard). Note that the operating system may impose additional limits on the number of characters that can be input to the terminal in a single record.
594	**severe (594): Comma delimiter disabled after left repositioning**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation

FOR$IOS_F6408. If you have record lengths that exceed the buffer size associated with the record, (for instance, the record is a file with the buffer set by BLOCKSIZE in the OPEN statement), either you should not do left tabbing within the record, or you should not use commas as field delimiters. This is because commas are disabled as input field delimiters if left tabbing leaves the record positioned in a previous buffer.

For example, consider you have a file `LONG.DAT` that is one continuous record with data fields separated by commas. You then set the buffer associated with the file to 512 bytes, read more than one buffer size of data, tab left to data in the previous buffer, and attempt to read further data, as follows:

```
    INTEGER value(300)
   OPEN (1, FILE = 'LONG.DAT', BLOCKSIZE = 512)s
   READ (1, 100) (value(i), i = 1, 300)s
100 FORMAT (290I2,TL50,10I2)
```

In this case, error 594 occurs.

599 **severe (599): File already connected to a different unit**

FOR$IOS_F6413. The program tried to connect an already connected file to a new unit.

A file can be connected to only one unit at a time.

600 **severe (600): Access not allowed**

FOR$IOS_F6414.

This error can be caused by one of the following:

- The filename specified in an OPEN statement was a directory.
- An OPEN statement tried to open a read-only file for writing.
- The file was opened with SHARE='DENYRW' by another process.

601 **severe (601): File already exists**

FOR$IOS_F6415. An OPEN statement specified STATUS='NEW' for a file that already exists.

602 **severe (602): File not found**

FOR$IOS_F6416. An OPEN statement specified STATUS='OLD' for a specified file or a directory path that does not exist.

603 **severe (603): Too many open files**

FOR$IOS_F6417. The program exceeded the number of open files the operating system allows.

604 **severe (604): Too many units connected**

FOR$IOS_F6418. The program exceeded the number of units that can be connected at one time. Units are connected with the OPEN statement.

605 **severe (605): Illegal structure for unformatted file**

FOR$IOS_F6419. The file was opened with FORM='UNFORMATTED' and ACCESS='SEQUENTIAL', but its internal physical structure was incorrect or inconsistent. Possible causes: the file was created in another mode or by a non-Fortran program.

606 **severe (606): Unknown unit number**

FOR$IOS_F6420. A statement such as BACKSPACE or ENDFILE specified a file that had not yet been opened. (The READ and WRITE statements do not cause this problem because they prompt you for a file if the file has not been opened yet.)

607 **severe (607): File read-only or locked against writing**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6421. The program tried to transfer data to a file that was opened in read-only mode or locked against writing. The error message may indicate a CLOSE error when the fault is actually coming from WRITE. This is because the error is not discovered until the program tries to write buffered data when it closes the file.
608	**severe (608): No space left on device** FOR$IOS_F6422. The program tried to transfer data to a file residing on a device (such as a hard disk) that was out of storage space.
609	**severe (609): Too many threads** FOR$IOS_F6423. Too many threads were active simultaneously. At most, 32 threads can be active at one time. Close any unnecessary processes or child windows within your application.
610	**severe (610): Invalid argument** FOR$IOS_F6424.
611	**severe (611): BACKSPACE illegal for SEQUENTIAL write-only files** FOR$IOS_F6425. The BACKSPACE statement is not allowed in files opened with MODE='WRITE' (write-only status) because BACKSPACE requires reading the previous record in the file to provide positioning. Resolve the problem by giving the file read access or by avoiding the BACKSPACE statement. Note that the REWIND statement is valid for files opened as write-only.
612	**severe (612): File not open for reading or file locked** FOR$IOS_F6500. The program tried to read from a file that was not opened for reading or was locked.
613	**severe (613): End of file encountered** FOR$IOS_F6501. The program tried to read more data than the file contains.
614	**severe (614): Positive integer expected in repeat field** FOR$IOS_F6502. When the *i**c* form is used in list-directed input, the *i* must be a positive integer. For example, consider the following statement: `READ(*,*) a, b` Input 2*56.7 is accepted, but input 2.1*56.7 returns error 614.
615	**severe (615): Multiple repeat field** FOR$IOS_F6503. In list-directed input of the form *i**c*, an extra repeat field was used. For example, consider the following: `READ(*,*) I, J, K` Input of 2*1*3 returns this error. The 2*1 means send two values, each 1; the *3 is an error.
616	**severe (616): Invalid number in input** FOR$IOS_F6504. Some of the values in a list-directed input record were not numeric. For example, consider the following: `READ(*,*) I, J` The preceding statement would cause this error if the input were: 123 'abc'.
617	**severe (617): Invalid string in input**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6505. A string item was not enclosed in single quotation marks.
618	**severe (618): Comma missing in COMPLEX input**
	FOR$IOS_F6506. When using list-directed input, the real and imaginary components of a complex number were not separated by a comma.
619	**severe (619): T or F expected in LOGICAL read**
	FOR$IOS_F6507. The wrong format was used for the input field for logical data. The input field for logical data consists of optional blanks, followed by an optional decimal point, followed by a T for true or F for false. The T or F may be followed by additional characters in the field, so that .TRUE. and .FALSE. are acceptable input forms.
620	**severe (620): Too many bytes read from unformatted record**
	FOR$IOS_F6508. The program tried to read more data from an unformatted file than the current record contained. If the program was reading from an unformatted direct file, it tried to read more than the fixed record length as specified by the RECL option. If the program was reading from an unformatted sequential file, it tried to read more data than was written to the record.
621	**severe (621): H or apostrophe edit descriptor illegal on input**
	FOR$IOS_F6509. Hollerith (H) or apostrophe edit descriptors were encountered in a format used by a READ statement.
622	**severe (622): Illegal character in hexadecimal input**
	FOR$IOS_F6510. The input field contained a character that was not hexadecimal. Legal hexadecimal characters are 0 - 9 and A - F.
623	**severe (623): Variable name not found**
	FOR$IOS_F6511. A name encountered on input from a namelist record is not declared in the corresponding NAMELIST statement.
624	**severe (624): Invalid NAMELIST input format**
	FOR$IOS_F6512. The input record is not in the correct form for NAMELIST input.
625	**severe (625): Wrong number of array dimensions**
	FOR$IOS_F6513. In NAMELIST input, an array name was qualified with a different number of subscripts than its declaration, or a non-array name was qualified.
626	**severe (626): Array subscript exceeds allocated area**
	FOR$IOS_F6514. A subscript was specified in NAMELIST input which exceeded the declared dimensions of the array.
627	**severe (627): Invalid subrange in NAMELIST input**
	FOR$IOS_F6515. A character item in namelist input was qualified with a subrange that did not meet the requirement that 1 <= e1 <= e2 <= len (where "len" is the length of the character item, "e1" is the leftmost position of the substring, and "e2" is the rightmost position of the substring).
628	**severe (628): Substring range specified on non-CHARACTER item**
	FOR$IOS_F6516. A non-CHARACTER item in namelist input was qualified with a substring range.
629	**severe (629): Internal file overflow**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6600. The program either overflowed an internal-file record or tried to write to a record beyond the end of an internal file.
630	**severe (630): Direct record overflow**
	FOR$IOS_F6601. The program tried to write more than the number of bytes specified in the RECL option to an individual record of a direct-access file.
631	**severe (631):Numeric field bigger than record size**
	FOR$IOS_F6602. The program tried to write a non-CHARACTER item across a record boundary in list-directed or namelist output. Only character constants can cross record boundaries.
632	**severe (632): Heap space limit exceeded**
	FOR$IOS_F6700. The program ran out of heap space. The ALLOCATE statement and various internal functions allocate memory from the heap. This error will be generated when the last of the heap space is used up.
633	**severe (633): Scratch file name limit exceeded**
	FOR$IOS_F6701. The program exhausted the template used to generate unique scratch-file names. The maximum number of scratch files that can be open at one time is 26.
634	**severe (634): D field exceeds W field in ES edit descriptor**
	FOR$IOS_F6970. The specified decimal length `d` exceeds the specified total field width `w` in an ES edit descriptor.
635	**severe (635): D field exceeds W field in EN edit descriptor**
	FOR$IOS_F6971. The specified decimal length `d` exceeds the specified total field width `w` in an EN edit descriptor.
636	**severe (636): Exponent of 0 not allowed in format**
	FOR$IOS_F6972.
637	**severe (637): Integer expected in format**

	FOR$IOS_F6980. An edit descriptor lacked a required integer value. For example, consider the following:
	`WRITE(*, 100) I, J`
	`100 FORMAT (I2, TL, I2)`
	The preceding code will cause this error because an integer is expected after TL.

638	**severe (638): Initial left parenthesis expected in format**
	FOR$IOS_F6981. A format did not begin with a left parenthesis (( ).
639	**severe (639): Positive integer expected in format**
	FOR$IOS_F6982. A zero or negative integer value was used in a format. Negative integer values can appear only with the P edit descriptor. Integer values of 0 can appear only in the `d` and `m` fields of numeric edit descriptors.
640	**severe (640): Repeat count on nonrepeatable descriptor**
	FOR$IOS_F6983. One or more BN, BZ, S, SS, SP, T, TL, TR, /, $, :, or apostrophe (') edit descriptors had repeat counts associated with them.
641	**severe (641): Integer expected preceding H, X, or P edit descriptor**
	FOR$IOS_F6984. An integer did not precede a (nonrepeatable) H, X, or P edit descriptor.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation

The correct formats for these descriptors are *n*H, *n*X, and *k*P, respectively, where *n* is a positive integer and *k* is an optionally signed integer.

642 **severe (642): N or Z expected after B in format**

FOR$IOS_F6985. To control interpretation of embedded and trailing blanks within numeric input fields, you must specify BN (to ignore them) or BZ (to interpret them as zeros).

643 **severe (643): Format nesting limit exceeded**

FOR$IOS_F6986. More than sixteen sets of parentheses were nested inside the main level of parentheses in a format.

644 **severe (644): '.' expected in format**

FOR$IOS_F6987. No period appeared between the w and d fields of a D, E, F, or G edit descriptor.

645 **severe (645): Unexpected end of format**

FOR$IOS_F6988. An incomplete format was used.

Improperly matched parentheses, an unfinished Hollerith (H) descriptor, or another incomplete descriptor specification can cause this error.

646 **severe (646): Unexpected character in format**

FOR$IOS_F6989. A character that cannot be interpreted as part of a valid edit descriptor was used in a format. For example, consider the following:

```
      WRITE(*, 100) I, J
  100 FORMAT (I2, TL4.5, I2)
```

The code will generate this error because TL4.5 is not a valid edit descriptor. An integer must follow TL.

647 **severe (647): M field exceeds W field in I edit descriptor**

FOR$IOS_F6990. In syntax Iw.m, the value of m cannot exceed the value of w.

648 **severe (648): Integer out of range in format**

FOR$IOS_F6991. An integer value specified in an edit descriptor was too large to represent as a 4-byte integer.

649 **severe (649): format not set by ASSIGN**

FOR$IOS_F6992. The format specifier in a READ, WRITE, or PRINT statement was an integer variable, but an ASSIGN statement did not properly assign it the statement label of a FORMAT statement in the same program unit.

650 **severe (650): Separator expected in format**

FOR$IOS_F6993. Within format specifications, edit descriptors must be separated by commas or slashes (/).

651 **severe (651): %c or $: nonstandard edit descriptor in format**

FOR$IOS_F6994.

652 **severe (652): Z: nonstandard edit descriptor in format**

FOR$IOS_F6995. Z is not a standard edit descriptor in format.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	If you want to transfer hexadecimal values, you must use the edit descriptor form Z`w[.m]`, where `w` is the field width and `m` is the minimum number of digits that must be in the field (including leading zeros).
653	**severe (653): DOS graphics not supported under Windows NT** FOR$IOS_F6996.
654	**severe (654): Graphics error** FOR$IOS_F6997. An OPEN statement in which IOFOCUS was TRUE, either explicitly or by default, failed because the new window could not receive focus. The window handle may be invalid, or closed, or there may be a memory resource problem.
655	**severe (655): Using QuickWin is illegal in console application** FOR$IOS_F6998. A call to QuickWin from a console application was encountered during execution.
656	**severe (656): Illegal 'ADVANCE' value** FOR$IOS_F6999. The ADVANCE option can only take the values 'YES' and 'NO'. ADVANCE='YES' is the default. ADVANCE is a READ statement option.
657	**severe (657): DIM argument to SIZE out of range** FOR$IOS_F6702. The argument specified for DIM must be greater than or equal to 1, and less than or equal to the number of dimensions in the specified array. Consider the following: `i = SIZE (array, DIM = dim)` In this case, `1 <= dim <= n`, where *n* is the number of dimensions in array.
658	**severe (657): Undefined POINTER used as argument to ASSOCIATED function** FOR$IOS_F6703. A POINTER used as an argument to the ASSOCIATED function must be defined; that is, assigned to a target, allocated, or nullified.
659	**severe (659): Reference to uninitialized POINTER** FOR$IOS_F6704. Except in an assignment statement, a pointer must not be referenced until it has been initialized: assigned to a target, allocated or nullified.
660	**severe (660): Reference to POINTER which is not associated** FOR$IOS_F6705. Except in an assignment statement and certain procedure references, a pointer must not be referenced until it has been associated: either assigned to a target or allocated.
661	**severe (661): Reference to uninitialized POINTER 'pointer'** FOR$IOS_F6706. Except in an assignment statement, a pointer must not be referenced until it has been initialized: assigned to a target, allocated or nullified.
662	**severe (662): reference to POINTER 'pointer' which is not associated** FOR$IOS_F6707. Except in an assignment statement and certain procedure references, a pointer must not be referenced until it has been associated: either assigned to a target or allocated.
663	**severe (663): Out of range: substring starting position 'pos' is less than 1** FOR$IOS_F6708. A substring starting position must be a positive integer variable or expression that indicates a position in the string: at least 1 and no greater than the length of the string.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
664	**severe (664): Out of range: substring ending position 'pos' is greater than string length 'len'** FOR$IOS_F6709. A substring ending position must be a positive integer variable or expression that indicates a position in the string: at least 1 and no greater than the length of the string.
665	**severe (665): Subscript 'n' of 'str' (value 'val') is out of range ('first:last')** FOR$IOS_F6710. The subscript for a substring within a string is not a valid string position: at least 1 and no greater than the length of the string.
666	**severe (666): Subscript 'n' of 'str' (value 'val') is out of range ('first:*')** FOR$IOS_F6711. The subscript for a substring within a string is not a valid string position: at least 1 and no greater than the length of the string.
667	**severe (667): VECTOR argument to PACK has incompatible character length** FOR$IOS_F6712. The character length of elements in the VECTOR argument to PACK is not the same as the character length of elements in the array to be packed.
668	**severe (668): VECTOR argument to PACK is too small** FOR$IOS_F6713. The VECTOR argument to PACK must have at least as many elements as there are true elements in MASK (the array that controls packing).
669	**severe (669): SOURCE and PAD arguments to RESHAPE have different character lengths** FOR$IOS_F6714. The character length of elements in the SOURCE and PAD arguments to PACK must be the same.
670	**severe (670): Element 'n' of SHAPE argument to RESHAPE is negative** FOR$IOS_F6715. The SHAPE vector specifies the shape of the reshaped array. Since an array cannot have a negative dimension, SHAPE cannot have a negative element.
671	**severe (671): SOURCE too small for specified SHAPE in RESHAPE, and no PAD** FOR$IOS_F6716. If there is no PAD array, the SOURCE argument to RESHAPE must have enough elements to make an array of the shape specified by SHAPE.
672	**severe (672): Out of memory** FOR$IOS_F6717. The system ran out of memory while trying to make the array specified by RESHAPE. If possible, reset your virtual memory size through the Windows* Control Panel, or close unnecessary applications and deallocate all allocated arrays that are no longer needed.
673	**severe (673): SHAPE and ORDER arguments to RESHAPE have different sizes ('size1' and 'size2')** FOR$IOS_F6718. ORDER specifies the order of the array dimensions given in SHAPE, and they must be vectors of the same size.
674	**severe (674): Element 'n' of ORDER argument to RESHAPE is out of range ('range')** FOR$IOS_F6719. The ORDER argument specifies the order of the dimensions of the reshaped array, and it must be a permuted list of (1, 2, ..., *n*) where *n* is the highest dimension in the reshaped array.
675	**severe (675): Value 'val' occurs twice in ORDER argument to RESHAPE** FOR$IOS_F6720. The ORDER vector specifies the order of the dimensions of the reshaped array, and it must be a permuted list of (1, 2, ..., *n*) where *n* is the highest dimension in the reshaped array. No dimension can occur twice.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
676	**severe (676): Impossible nextelt overflow in RESHAPE** FOR$IOS_F6721.
677	**severe (677): Invalid value 'dim' for argument DIM for SPREAD of rank 'rank' source** FOR$IOS_F6722. The argument specified for DIM to SPREAD must be greater than or equal to 1, and less than or equal to one larger than the number of dimensions (rank) of SOURCE. Consider the following statement: `result = SPREAD (SOURCE= array, DIM = dim, NCOPIES = k)` In this case, 1 <= dim <= *n*+ 1, where *n*is the number of dimensions in array.
678	**severe (678): Complex zero raised to power zero** FOR$IOS_F6723. Zero of any type (complex, real, or integer) cannot be raised to zero power.
679	**severe (679): Complex zero raised to negative power** FOR$IOS_F6724. Zero of any type (complex, real, or integer) cannot be raised to a negative power. Raising to a negative power inverts the operand.
680	**severe (680): Impossible error in NAMELIST input** FOR$IOS_F6725.
681	**severe (681):DIM argument to CSHIFT ('dim') is out of range** FOR$IOS_F6726. The optional argument DIM specifies the dimension along which to perform the circular shift, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array to be shifted. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in the array to be shifted.
682	**severe (682): DIM argument ('dim') to CSHIFT is out of range (1:'n')** FOR$IOS_F6727. The optional argument DIM specifies the dimension along which to perform the circular shift, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array to be shifted. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in the array to be shifted.
683	**severe (683): Shape mismatch (dimension 'dim') between ARRAY and SHIFT in CSHIFT** FOR$IOS_F6728. The SHIFT argument to CSHIFT must be either scalar or an array one dimension smaller than the shifted array. If an array, the shape of the SHIFT must conform to the shape of the array being shifted in every dimension except the one being shifted along.
684	**severe (684): Internal error - bad arguments to CSHIFT_CA** FOR$IOS_F6729.
685	**severe (685): Internal error - bad arguments to CSHIFT_CAA** FOR$IOS_F6730.
686	**severe (686): DATE argument to DATE_AND_TIME is too short (LEN='len')** FOR$IOS_F6731. The character DATE argument must have a length of at least eight to contain the complete value.
687	**severe (687): TIME argument to DATE_AND_TIME is too short (LEN='len')** FOR$IOS_F6732. The character TIME argument must have a length of at least ten to contain the complete value.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
688	**severe (688): ZONE argument to DATE_AND_TIME is too short (LEN='len')** FOR$IOS_F6733. The character ZONE argument must have a length of at least five to contain the complete value.
689	**severe (689): VALUES argument to DATE_AND_TIME is too small ('size' elements)** FOR$IOS_F6734. The integer VALUES argument must be a one-dimensional array with a size of at least eight to hold all returned values.
690	**severe (690): Out of range: DIM argument to COUNT has value 'dim'** FOR$IOS_F6735. The optional argument DIM specifies the dimension along which to count true elements of MASK, and must be greater than or equal to 1 and less than or equal to the number of dimensions in MASK. That is, 1 <= DIM <= *n*, where *n* is the number of dimensions in MASK.
691	**severe (691): Out of range: DIM argument to COUNT has value 'dim' with MASK of rank 'rank'** FOR$IOS_F6736. The optional argument DIM specifies the dimension along which to count true elements of MASK, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) in MASK. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in MASK.
692	**severe (692): Out of range: DIM argument to PRODUCT has value 'dim'** FOR$IOS_F6737. The optional argument DIM specifies the dimension along which to compute the product of elements in an array, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in array holding the elements to be multiplied.
693	**severe (693): Out of range: DIM argument to PRODUCT has value 'dim' with ARRAY of rank 'rank'** FOR$IOS_F6738. The optional argument DIM specifies the dimension along which to compute the product of elements in an array, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) of the array. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in array holding the elements to be multiplied.
694	**severe (694): Out of range: DIM argument to SUM has value 'dim' with ARRAY of rank 'rank'** FOR$IOS_F6739. The optional argument DIM specifies the dimension along which to sum the elements of an array, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) of the array. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in array holding the elements to be summed.
695	**severe (695): Real zero raised to zero power** FOR$IOS_F6740. Zero of any type (real, complex, or integer) cannot be raised to zero power.
696	**severe (696): Real zero raised to negative power** FOR$IOS_F6741. Zero of any type (real, complex, or integer) cannot be raised to a negative power. Raising to a negative power inverts the operand.
697	**severe (697): Out of range: DIM argument to SUM has value 'dim'** FOR$IOS_F6742. The optional argument DIM specifies the dimension along which to sum the elements of an array, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in array holding the elements to be summed.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
698	**severe (698): DIM argument ('dim') to EOSHIFT is out of range (1:'n')** FOR$IOS_F6743. The optional argument DIM specifies the dimension along which to perform an end-off shift in an array, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in array holding the elements to be shifted.
699	**severe (699): Shape mismatch (dimension 'dim') between ARRAY and BOUNDARY in EOSHIFT** FOR$IOS_F6744. The BOUNDARY argument to EOSHIFT must be either scalar or an array one dimension smaller than the shifted array. If an array, the shape of the BOUNDARY must conform to the shape of the array being shifted in every dimension except the one being shifted along.
700	**severe (700): DIM argument to EOSHIFT is out of range ('dim')** FOR$IOS_F6745. The optional argument DIM specifies the dimension along which to perform an end-off shift in an array, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in array holding the elements to be shifted.
701	**severe (701): Shape mismatch (dimension 'dim') between ARRAY and SHIFT in EOSHIFT** FOR$IOS_F6746. The SHIFT argument to EOSHIFT must be either scalar or an array one dimension smaller than the shifted array. If an array, the shape of the SHIFT must conform to the shape of the array being shifted in every dimension except the one being shifted along.
702	**severe (702): BOUNDARY argument to EOSHIFT has wrong LEN ('len1 instead of len2')** FOR$IOS_F6747. The character length of elements in the BOUNDARY argument and in the array being end-off shifted must be the same.
703	**severe (703): BOUNDARY has LEN 'len' instead of 'len' to EOSHIFT** FOR$IOS_F6748.
704	**severe (704): Internal error - bad arguments to EOSHIFT** FOR$IOS_F6749.
705	**severe (705): GETARG: value of argument 'num' is out of range** FOR$IOS_F6750. The value used for the number of the command-line argument to retrieve with GETARG must be 0 or a positive integer. If the number of the argument to be retrieved is greater than the actual number of arguments, blanks are returned, but no error occurs.
706	**severe (706): FLUSH: value of LUNIT 'num' is out of range** FOR$IOS_F6751. The unit number specifying which I/O unit to flush to its associated file must be an integer between 0 and 2**31-1, inclusive. If the unit number is valid, but the unit is not opened, error F6752 is generated.
707	**severe (707): FLUSH: Unit 'n' is not connected** FOR$IOS_F6752. The I/O unit specified to be flushed to its associated file is not connected to a file.
708	**severe (708): Invalid string length ('len') to ICHAR** FOR$IOS_F6753. The character argument to ICHAR must have length of one.
709	**severe (709): Invalid string length ('len') to IACHAR**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	FOR$IOS_F6754. The character argument to IACHAR must have length of one.
710	**severe (710): Integer zero raised to negative power**
	FOR$IOS_F6755. Zero of any type (integer, real, or complex) cannot be raised to a negative power. Raising to a negative power inverts the operand.
711	**severe (711): INTEGER zero raised to zero power**
	FOR$IOS_F6756. Zero of any type (integer, real, or complex) cannot be raised to zero power.
712	**severe (712): SIZE argument ('size') to ISHFTC intrinsic out of range**
	FOR$IOS_F6757. The argument SIZE must be positive and must not exceed the bit size of the integer being shifted. The bit size of this integer can be determined with the function BIT_SIZE.
713	**severe (713): SHIFT argument ('shift') to ISHFTC intrinsic out of range**
	FOR$IOS_F6758. The argument SHIFT to ISHFTC must be an integer whose absolute value is less than or equal to the number of bits being shifted: either all bits in the number being shifted or a subset specified by the optional argument SIZE.
714	**severe (714): Out of range: DIM argument to LBOUND has value 'dim'**
	FOR$IOS_F6759. The optional argument DIM specifies the dimension whose lower bound is to be returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, 1 <= DIM <= *n*, where *n* is the number of dimensions in array.
715	**severe (715): Out of range: DIM argument ('dim') to LBOUND greater than ARRAY rank 'rank'**
	FOR$IOS_F6760. The optional argument DIM specifies the dimension whose lower bound is to be returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) in the array. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in array.
716	**severe (716): Out of range: DIM argument to MAXVAL has value 'dim'**
	FOR$IOS_F6761. The optional argument DIM specifies the dimension along which maximum values are returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, 1 <= DIM <= *n*, where *n* is the number of dimensions in array.
717	**severe (717): Out of range: DIM argument to MAXVAL has value 'dim' with ARRAY of rank 'rank'**
	FOR$IOS_F6762. The optional argument DIM specifies the dimension along which maximum values are returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) in the array. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in array.
718	**severe (718): Cannot allocate temporary array -- out of memory**
	FOR$IOS_F6763. There is not enough memory space to hold a temporary array. Dynamic memory allocation is limited by several factors, including swap file size and memory requirements of other applications that are running. If you encounter an unexpectedly low limit, you may need to reset your virtual memory size through the Windows Control Panel or redefine the swap file size. Allocated arrays that are no longer needed should be deallocated.
719	**severe (719): Attempt to DEALLOCATE part of a larger object**
	FOR$IOS_F6764. An attempt was made to DEALLOCATE a pointer to an array subsection or an element within a derived type. The whole data object must be deallocated; parts cannot be deallocated.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
720	**severe (720): Pointer in DEALLOCATE is ASSOCIATED with an ALLOCATABLE array** FOR$IOS_F6765. Deallocating a pointer associated with an allocatable target is illegal. Instead, deallocate the target the pointer points to, which frees memory and disassociates the pointer.
721	**severe (721): Attempt to DEALLOCATE an object which was not allocated** FOR$IOS_F6766. You cannot deallocate an array unless it has been previously allocated. You cannot deallocate a pointer whose target was not created by allocation. The intrinsic function ALLOCATED can be used to determine whether an allocatable array is currently allocated.
722	**severe (722): Cannot ALLOCATE scalar POINTER -- out of memory** FOR$IOS_F6767. There is not enough memory space to allocate the pointer. Dynamic memory allocation is limited by several factors, including swap file size and memory requirements of other applications that are running. If you encounter an unexpectedly low limit, you may need to reset your virtual memory size through the Windows* Control Panel or redefine the swap file size. Allocated arrays that are no longer needed should be deallocated.
723	**severe (723): DEALLOCATE: object not allocated/associated** FOR$IOS_F6768. You cannot deallocate an array unless it has been previously allocated. You cannot deallocate a pointer whose target was not created by allocation, or a pointer that has undefined association status. The intrinsic function ALLOCATED can be used to determine whether an allocatable array is currently allocated.
724	**severe (724): Cannot ALLOCATE POINTER array -- out of memory** FOR$IOS_F6769. There is not enough memory space to allocate the POINTER array. Dynamic memory allocation is limited by several factors, including swap file size and memory requirements of other applications that are running. If you encounter an unexpectedly low limit, you may need to reset your virtual memory size through the Windows* Control Panel or redefine the swap file size. Allocated arrays that are no longer needed should be deallocated.
725	**severe (725): DEALLOCATE: Array not allocated** FOR$IOS_F6770. It is illegal to DEALLOCATE an array that is not allocated. You can check the allocation status of an array before deallocating with the ALLOCATED function.
726	**severe (726): DEALLOCATE: Character array not allocated** FOR$IOS_F6771. It is illegal to DEALLOCATE an array that is not allocated. You can check the allocation status of an array before deallocating with the ALLOCATED function.
727	**severe (727): Cannot ALLOCATE allocatable array -- out of memory** FOR$IOS_F6772. There is not enough memory space to hold the array. Dynamic memory allocation is limited by several factors, including swap file size and memory requirements of other applications that are running. If you encounter an unexpectedly low limit, you may need to reset your virtual memory size through the Windows* Control Panel or redefine the swap file size. Allocated arrays that are no longer needed should be deallocated.
728	**severe (728): Cannot allocate automatic object -- out of memory** FOR$IOS_F6773. There is not enough memory space to hold the automatic data object. Dynamic memory allocation is limited by several factors, including swap file size and memory requirements of other applications that are running. If you encounter an unexpectedly low limit, you may need to reset your virtual memory size through the Windows* Control Panel or redefine the swap file size. Allocated arrays that are no longer needed should be deallocated.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation

An automatic data object is an object that is declared in a procedure subprogram or interface, is not a dummy argument, and depends on a nonconstant expression. For example:

```
SUBROUTINE  EXAMPLE (N)
  DIMENSION A (N, 5), B(10*N)
```

The arrays `A` and `B` in the example are automatic data objects.

729 **severe (729): DEALLOCATE failure: ALLOCATABLE array is not ALLOCATED**

FOR$IOS_F6774. It is illegal to DEALLOCATE an array that is not allocated. You can check the allocation status of an array before deallocating with the ALLOCATED function.

730 **severe (730): Out of range: DIM argument to MINVAL has value 'dim'**

FOR$IOS_F6775. The optional argument DIM specifies the dimension along which minimum values are returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in array.

731 **severe (731): Out of range: DIM argument to MINVAL has value 'dim' with ARRAY of rank 'rank'**

FOR$IOS_F6776. The optional argument DIM specifies the dimension along which minimum values are returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) in the array. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in array.

732 **severe (732): P argument to MOD is double precision zero**

FOR$IOS_F6777. `MOD(A, P)` is computed as *A* - INT(*A*,*P*) * *P*. *P* cannot be zero.

733 **severe (733): P argument to MOD is integer zero**

FOR$IOS_F6778. `MOD(A, P)` is computed as *A* - INT(*A*,*P*) * *P*. *P* cannot be zero.

734 **severe (734): P argument to MOD is real zero**

FOR$IOS_F6779. `MOD(A, P)` is computed as *A* - INT(*A*,*P*) * *P*. *P* cannot be zero.

735 **severe (735): P argument to MODULO is real zero**

FOR$IOS_F6780. `MODULO(A, P)` for real numbers is computed as *A* - FLOOR(*A*,*P*) * P. So, *P* cannot be zero.

736 **severe (736): P argument to MODULO is zero**

FOR$IOS_F6781. In the function, `MODULO(A, P)`, *P* cannot be zero.

737 **severe (737): Argument S to NEAREST is zero**

FOR$IOS_F6782. The sign of the *S* argument to `NEAREST(X, S)` determines the direction of the search for the nearest number to *X*, and cannot be zero.

738 **severe (738): Heap storage exhausted**

FOR$IOS_F6783.

739 **severe (739): PUT argument to RANDOM_SEED is too small**

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation

FOR$IOS_F6784. The integer array `PUT` must be greater than or equal to the number of integers the processor uses to set the seed value. This number can be determined by calling RANDOM_SEED with the SIZE argument. For example:

```
INTEGER, ALLOCATABLE SEED
CALL RANDOM_SEED( )           ! initialize processor
CALL RANDOM_SEED(SIZE = K)    ! get size of seed
ALLOCATE SEED(K)              ! allocate array
CALL RANDOM_SEED(PUT = SEED)  ! set the seed
```

NOTE
RANDOM_SEED can be called with at most one argument at a time.

740 **severe (740): GET argument to RANDOM_SEED is too small**

FOR$IOS_F6785. The integer array GET must be greater than or equal to the number of integers the processor uses to set the seed value. This number can be determined by calling RANDOM_SEED with the SIZE argument. For example:

```
INTEGER, ALLOCATABLE SEED
CALL RANDOM_SEED( )           ! initialize processor
CALL RANDOM_SEED(SIZE = K)    ! get size of seed
ALLOCATE SEED(K)              ! allocate array
CALL RANDOM_SEED(GET = SEED)  ! get the seed
```

NOTE
RANDOM_SEED can be called with at most one argument at a time.

741 **severe (741): Recursive I/O reference**

FOR$IOS_F6786.

742 **severe (742): Argument to SHAPE intrinsic is not PRESENT**

FOR$IOS_F6787.

743 **severe (743): Out of range: DIM argument to UBOUND had value 'dim'**

FOR$IOS_F6788. The optional argument DIM specifies the dimension whose upper bound is to be returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions in the array. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in array.

744 **severe (744): DIM argument ('dim') to UBOUND greater than ARRAY rank 'rank'**

FOR$IOS_F6789. The optional argument DIM specifies the dimension whose upper bound is to be returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) in the array. That is, 1 <= DIM <= *n*, where *n*is the number of dimensions in array.

745 **severe (745): Out of range: UBOUND of assumed-size array with DIM==rank ('rank')**

FOR$IOS_F6790. The optional argument DIM specifies the dimension whose upper bound is to be returned.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	An assumed-size array is a dummy argument in a subroutine or function, and the upper bound of its last dimension is determined by the size of actual array passed to it. Assumed-size arrays have no determined shape, and you cannot use UBOUND to determine the extent of the last dimension. You can use UBOUND to determine the upper bound of one of the fixed dimensions, in which case you must pass the dimension number along with the array name.
746	**severe (746): Out of range: DIM argument ('dim') to UBOUND greater than ARRAY rank** FOR$IOS_F6791. The optional argument DIM specifies the dimension whose upper bound is to be returned, and must be greater than or equal to 1 and less than or equal to the number of dimensions (rank) in the array. That is, 1 <= DIM <= *n*, where *n* is the number of dimensions in array.
747	**severe (747): Shape mismatch: Dimension 'shape' extents are 'ext1' and 'ext2'** FOR$IOS_F6792.
748	**severe (748): Illegal POSITION value** FOR$IOS_F6793. An illegal value was used with the POSITION specifier. POSITION accepts the following values: • 'ASIS' (the default) • 'REWIND' - on Fortran I/O systems, this is the same as 'ASIS' • 'APPEND'
749	**severe (749): Illegal ACTION value** FOR$IOS_F6794. An illegal value was used with the ACTION specifier. ACTIO accepts the following values: • 'READ' • 'WRITE' • 'READWRITE' - the default
750	**severe (750): DELIM= specifier not allowed for an UNFORMATTED file** FOR$IOS_F6795. The DELIM specifier is only allowed for files connected for formatted data transfer. It is used to delimit character constants in list-directed an namelist output.
751	**severe (751): Illegal DELIM value** FOR$IOS_F6796. An illegal value was used with the DELIM specifier. DELIM accepts the following values: • 'APOSTROPHE' • 'QUOTE' • 'NONE' - the default
752	**severe (752): PAD= specifier not allowed for an UNFORMATTED file** FOR$IOS_F6797. The PAD specifier is only allowed for formatted input records. It indicates whether the formatted input record is padded with blanks when an input list and format specification requires more data than the record contains.
753	**severe (753): Illegal PAD= value** FOR$IOS_F6798. An illegal value was used with the PAD specifier. PAD accepts the following values: • 'NO'

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
	• 'YES' - the default
754	**severe (754): Illegal CARRIAGECONTROL=value** FOR$IOS_F6799. An illegal value was used with the CARRIAGECONTROL specifier. CARRIAGECONTROL accepts the following values: • 'FORTRAN' - default if the unit is connected to a terminal or console • 'LIST' - default for formatted files • 'NONE' - default for unformatted files
755	**severe (755): SIZE= specifier only allowed with ADVANCE='NO'** FOR$IOS_F6800. The SIZE specifier can only appear in a formatted, sequential READ statement that has the specifier ADVANCE='NO' (indicating non-advancing input).
756	**severe (756): Illegal character in binary input** FOR$IOS_F6801.
757	**severe (757): Illegal character in octal input** FOR$IOS_F6802.
758	**severe (758): End of record encountered** FOR$IOS_F6803.
759	**severe (759): Illegal subscript in namelist input record** FOR$IOS_F6804.
760	**severe (760): Error reported by 'EnumSystemLocales'** FOR$IOS_F6805.
761	**severe (761): Cannot set environment variable %s** FOR$IOS_F6806.
762	**info(762): Error freeing internal data structure.** FOR$IOS_F6807.
772	**severe (772): Image number %d is not a valid image number; valid numbers are 1 to %d** FOR$IOS_F6817. A reference has been made to an image number that is not a valid image number.
774	**severe (774): Image-set array expression must not contain repeated values** FOR$IOS_F6819. A SYNC IMAGES <image-list> statement was attempted. The <image-list> contains duplicate values. This is not permitted by the standard.
775	**severe (775): The lock variable in a LOCK statement is already locked by the executing image** FOR$IOS_F6820. An attempt was made to use a LOCK statement on a lock. However, that lock has already been locked by this image.
776	**severe (776): The lock variable in an UNLOCK statement is not already locked by the executing image** FOR$IOS_F6821. An attempt was made to use an UNLOCK statement on a lock. However, that lock is currently unlocked; it has not been locked by this image.

Number	Severity Level, Number, and Message Text; Condition Symbol and Explanation
777	**severe (777): The lock variable in a LOCK statement is already locked by another image** FOR$IOS_F6822. An attempt was made to use a LOCK statement on a lock. However, that lock is already locked by another image.
778	**severe (778): One of the images to be synchronized with has terminated** FOR$IOS_F6823. The code has tried to synchronize with a set of images using a SYNC statement. One of the images to be synchronized with has already terminated.
779	**info (779): In coarray image %d\n** FOR$IOS_F6824. This is issued as part of the stack traceback from a fatal error. The image listed is the one in which the error happened.
780	**severe (780): The lock variable in an UNLOCK statement is locked by another image** FOR$IOS_F6825. An attempt was made to use a coarray UNLOCK operation on a lock. However, that lock is locked by another image. This may be the result of an error in the program that causes the code to think it has a lock when it does not.
781	**error (781): Only image 1 may read from unit '*'** FOR$IOS_F6826. It is a coarray rule that only image 1 may read from the 'console'.

[1] Identifies errors not returned by IOSTAT.

Signal Handling (Linux* and macOS* only)

A `signal` is an abnormal event generated by one of various sources, such as:

- A user of a terminal.
- Program or hardware error.
- Request of another program.
- When a process is stopped to allow access to the control terminal.

You can optionally set certain events to issue signals, for example:

- When a process resumes after being stopped
- When the status of a child process changes
- When input is ready at the terminal

Some signals terminate the receiving process if no action is taken (optionally creating a `core` file), while others are simply ignored unless the process has requested otherwise.

Except for certain signals, calling the `signal` or `sigaction` routine allows specified signals to be ignored or causes an interrupt (transfer of control) to the location of a user-written signal handler.

You can establish one of the following actions for a signal with a call to `signal`:

- Ignore the specified signal (identified by number).
- Use the default action for the specified signal, which can reset a previously established action.
- Transfer control from the specified signal to a procedure to receive the signal, specified by name.

Calling the `signal` routine lets you change the action for a signal, such as intercepting an operating system signal and preventing the process from being stopped.

The table below shows the signals that the Intel® Fortran RTL arranges to catch when a program is started:

Signal	Intel® Fortran RTL message
SIGFPE	`Floating-point exception` (number 75)
SIGINT	`Process interrupted` (number 69)
SIGIOT	`IOT trap signal` (number 76)
SIGQUIT	`Process quit` (number 79)
SIGSEGV	`Segmentation fault` (number 174)
SIGTERM	`Process killed` (number 78)

Calling the `signal` routine (specifying the numbers for these signals) results in overwriting the signal-handling facility set up by the Intel® Fortran RTL. The only way to restore the default action is to save the returned value from the first call to `signal`.

When using a debugger, it may be necessary to enter a command to allow the Intel® Fortran RTL to receive and handle the appropriate signals.

Overriding the Default Run-Time Library Exception Handler

To override the default run-time library exception handler on Linux* and macOS*, your application must call `signal` to change the action for the signal of interest.

For example, assume that you want to change the signal action to cause your application to call `abort()` and generate a `core` file.

The following example adds a function named `clear_signal_` to call `signal()` and change the action for the `SIGABRT` signal:

```
#include <signal.h>
  void clear_signal_() { signal (SIGABRT, SIG_DFL); }

  int myabort_() {
    abort();
    return 0;
}
```

A call to the `clear_signal()` local routine must be added to main. Make sure that the call appears before any call to the local `myabort()` routine:

```
program aborts
integer i

call clear_signal()

i = 3
if (i < 5) then
call myabort()
end if
end
```

Advanced Exception and Termination Handling

Advanced Exception and Termination Handling Overview

This section provides information about exception and termination handling issues.

To employ some of the exception handling techniques presented, you will need a C language compiler, which has support for `try-except` constructs or some other form of support for structured exception handling.

Providing Your Own Exception Termination Handler

General Default Exception Handling

The Intel® Visual Fortran run-time system provides minimal default support for exception handling, console event handling, and application termination rundown.

The default exception handling support provided depends on the type of application (project type) being developed:

- A default exception handler is included with Fortran Console, Fortran QuickWin, and Fortran Standard Graphics applications.
- No default exception handler is included with Fortran Windows or Fortran DLL applications or with C Console applications that contain Fortran procedures.

When you use the default exception handler, all events are enabled. You cannot connect or disconnect individual events from the default Fortran exception handler. However, you can disable the Fortran exception handler, and enable your own. To disable the exception handler, set the `FOR_IGNORE_EXCEPTIONS` environment variable to TRUE.

Most exceptions captured by the Intel® Visual Fortran default handler are dealt with as severe errors. When an exception occurs, the Fortran run-time system will display an error message and traceback output as described in Understanding Run-Time Errors. A run-time error with a severe error (as described in Run-Time Message Display and Format) causes the Intel® Visual Fortran run-time system to terminate the application. Most I/O programming errors are also severe and will terminate an application.

I/O programming errors are not exceptions and cannot be caught by an exception handler. An unhandled I/O programming error is reported through a different mechanism in the Intel® Visual Fortran run-time system. Regardless of the application (project) type, unhandled I/O programming error will generate an error message and traceback output.

Run-Time Message Display and Format
Understanding Run-Time Errors
project type

Default Console Event Handling

When the Fortran run-time system is initialized, it establishes a default console event handler through the `SetConsoleCtrlHandler` Windows API routine. The default handler will respond to the following event types:

- `CTRL_C_EVENT`
- `CTRL_BREAK_EVENT`
- `CTRL_CLOSE_EVENT`

These event types will result in an orderly program abort with an appropriate diagnostic message. To disable this default call to `SetConsoleCtrlHandler`, set an environment variable named `FOR_DISABLE_CONSOLE_CTRL_HANDLER` to the value YES (Y or y), or TRUE (T or t), or a number greater than zero.

Other console events such as a `CTRL_LOGOFF_EVENT` or `CTRL_SHUTDOWN_EVENT` are not handled by the default handler. The handler is notified of these events but returns FALSE to the operating system. This allows an Intel® Visual Fortran application activated as a Windows* service to continue execution when a user logs off.

See Also

Establishing Console Event Handlers

General Default Termination Handling

When a Fortran Console, Fortran QuickWin, or Fortran Standard Graphics application terminates execution, either by normal termination or due to a severe error or exception, the following actions are taken by the Fortran run-time system:

- Any Open files are closed and the requested `DISPOSITION` operations are performed.
- With a QuickWin application, any open QuickWin windows are closed.
- The C run-time `exit()` routine is called with the status code to return to the operating system. The C run-time `exit()` routine will call the Windows API routine `ExitProcess` to terminate the process. (See `crt0dat.c` in the C run-time sources).

In a Fortran DLL or Fortran Windows* application, any unhandled I/O programming errors will cause the following actions:

- Any Open files are closed and the requested `DISPOSITION` operations are performed.
- The C run-time `exit()` routine is called with the status code to return to the operating system. The C run-time `exit()` routine will call the Windows API routine `ExitProcess` to terminate the process. (See `crt0dat.c` in the C run-time sources.)

Any unhandled exceptions that occur in a Fortran DLL or Fortran Windows application will have application dependent behavior. Since there is no Fortran default handler present, the behavior depends on what you provide for a handler. If you do not explicitly provide a handler, the default mechanisms provided in your main program will determine the behavior. In a Fortran Windows* application, the C run-time system will terminate the application.

Handlers for the Application (Project) Types

To understand how Intel® Fortran handlers are incorporated into your application, and how you might incorporate your own handlers, you should understand how each application type is constructed. This section describes handlers for the various application (project) types.

Fortran Console Applications

Fortran Console applications resemble C applications, with the Intel® Fortran run-time system providing the C `main()` function.

The entry point for a console application is specified as the C library's `mainCRTStartup()` routine (see module `crt0.c` in the C run-time sources). This initializes the C run-time system, wraps the Fortran run-time system `main()` in a try-except construct using the C run-time's exception filter (`_XcptFilter()`), and calls the Fortran run-time system `main()` routine in run-time module `for_main.c`. In simplified form, it looks like this:

```
 mainCRTStartup() {
  C initialization code here
  __try {
       more initialization code here
       mainret = main()      /* calls Fortran run-time main() */
       exit(mainret)
  } __except ( _XcptFilter() )
         { _exit ( GetExceptionCode() ) }
}
```

In the Fortran run-time system, `main()` initializes the Fortran run-time system (if not already initialized), wraps a try-except construct around `MAIN__` (the entry point to the Fortran code) with a filter expression that invokes the Fortran run-time system default handler on exceptions, and calls `MAIN__`. It also wraps a try-finally construct around all of this so run-time system clean up gets done (with for_rtl_finish_) when the program exits. In simplified form, it looks like this:

```
main() {
  __try {
     __try {
           for_rtl_init()
           MAIN__
     } __except ( expression-invoking-fortran-default-handler )
              { }
  } __finally { for_rtl_finish() }
}
```

In the Fortran code, symbol `MAIN__` is the entry point called by the run-time system's main() routine. `MAIN__` has the code to do any further run-time initialization or checks. For example, if the user compiled with the non-default `fpe[:]0` option, there would be a call to FOR_SET_FPE to tell the run-time system how to setup/react to floating-point exceptions.

Fortran QuickWin and Standard Graphics Applications

A Fortran QuickWin (including Fortran Standard Graphics) application is a specialized windows application where Intel® Visual Fortran provides the `WinMain()` function.

The entry point for a QuickWin application is specified as the C library `WinMainCRTStartup()` routine (see module `crt0.c` in the C run-time sources). This gets the C run-time initialized, wraps the Intel® Visual Fortran defined `WinMain()` in a try-except construct using the C run-time exception filter (`_XcptFilter()`) and calls the Intel® Visual Fortran defined `WinMain()` routine. In simplified form, it looks like this:

```
WinMainCRTStartup() {
  C initialization code here
  __try {
        more initialization code here
        mainret = WinMain()      /* calls qwin library WinMain() */
        exit(mainret)
  } __except ( _XcptFilter() )
           { _exit ( GetExceptionCode() ) }
}
```

In the QuickWin library, `WinMain()` performs some initialization specific to QuickWin, creates a new thread which begins execution at `QWINForkMain`, and then sits in a message loop directing the action. The message loop is wrapped in a try-except-finally construct which invokes the Fortran run-time system default handler if an exception occurs, and calls for_rtl_finish_ at exit. `QWINForkMain()` running in the other thread calls the Fortran run-time system `main()`, which in turn calls `MAIN__`. In simplified form, it looks like this:

```
WinMain() {
  Initialization code here
  BeginThreadEx (..., QWINForkMain, ... )
  __try {
     __try {
           the message loop...
           for_rtl_finish()
           return (msg.wParam)
     } __except ( expression-invoking-default-fortran-handler )
              { }
  } __finally {
        for_rtl_finish()
```

```
        return (msg.wParam)
    }
  }
```

`QWINForkMain` resembles the following:

```
  QWINForkMain() {
    main()      /* calls the CVF rtl main() which calls MAIN__ */
    cleanup and exit...
  }
```

The routines `main()` and `MAIN__` are the same as previously described for a Fortran Console application.

Fortran DLL Applications

A Fortran DLL is a collection of one or more routines that you generally call from some other main program. As such, the routines execute in the structure and environment created by the code which calls into the DLL. You can provide DLL initialization through a `DllMain()` function, but you probably would control general application initialization from the main program.

There are no automatic provisions for any exception handler in a DLL. There is no environment initialization except what you provide. Of course, if your main application is also written in Fortran, you will get the default Fortran handlers provided by that application type.

Fortran Windows* Applications

A Fortran Windows* application has as its entry point `WinMainCRTStartup()` and each user writes the code for the `WinMain` function declaration and interface. Examples are provided to show how to do this in Fortran code. The compiler still generates symbol `MAIN__` with the initialization code in place, but nothing calls `MAIN__`. Also, nothing connects up to the run-time system's `main()` so there's no try-except construct to hook in the default Intel® Fortran handler, and no run-time system initialization or cleanup. In simplified form, it looks like this:

```
  WinMainCRTStartup() {
    C initialization code
    __try {
          more initialization code
          mainret = WinMain()      /* calls the user's WinMain() */
          exit(mainret)
    } __except ( _XcptFilter() )
              { _exit ( GetExceptionCode() ) }
  }
```

The Fortran code contains:

```
  integer(4) function WinMain( HANDLE, HANDLE, LPSTR, int )
  ...
  ! whatever Fortran the user codes here...
  ...
  end
```

Providing Your Own Exception/Termination Handler

For Fortran Console, Fortran QuickWin, and Fortran Standard Graphics applications, the default exception and termination handlers are probably sufficient to meet most needs. As described in Handlers for the Application (Project) Types, Fortran DLL and Fortran Windows* applications do not have default handlers.

Whenever the default exception and termination handlers do not meet all your needs, consider providing your own handler. This is really a question you need to answer for each specific application. Some examples:

- Suppose your application creates some files during the course of its execution and you do not want to leave them on the disk if an unexpected error or exception occurs. The default termination actions only cause the files to be closed if you specifically opened them with DISPOSE='DELETE'. But suppose you do not want them deleted under normal termination. If an unexpected event occurs, you need to get control so you can clean up these files as needed.
- Perhaps your application can recover from a particular situation, for example, an integer divide-by-zero operation. You want to gain control if that exception occurs and deal with it.
- Perhaps you just want to output an application-specific error message when an exception occurs.
- You are building a Fortran DLL to run under a Visual Basic* GUI and you do not want the DLL to crash the application if an exception occurs in the DLL.
- Your code takes a lock on a global resource and you want to be sure and release the resource if an unexpected event occurs.

The list of possibilities is endless and only the application developer can anticipate particular needs.

The most general way to establish your own handler is to use Windows* structured exception handling capabilities (SEH). For lighter-weight exception handling requirements, you can use SIGNALQQ.

Using Windows* Structured Exception Handling (SEH) Overview
List of Run-Time Error Messages

Using Windows* Structured Exception Handling (SEH)

Using Windows* Structured Exception Handling (SEH) Overview

Windows* provides a robust exception and termination handling mechanism called Structured Exception Handling (SEH). Structured exception handling requires support in both the operating system and compilers. Unfortunately, Intel® Fortran does not include extensions for SEH support, but you can still take advantage of this powerful tool. By introducing a bit of C code in your application, you can use SEH to meet your exception handling needs.

A good reference on this subject is Chapter 16 in the book *Advanced Windows* (Third Edition) by Jeffrey Richter.

Custom Handlers for Fortran Console, Fortran QuickWin, and Fortran Standard Graphics Applications

Fortran Console and Fortran QuickWin (and Fortran Standard Graphics) applications have the full benefit of the Fortran default exception and error handling processing facilities. You may, however, want to supplement or replace the default facilities.

Custom Handlers for Fortran DLL Applications

There are two aspects to creating custom handlers for Fortran DLL applications:

- Containing errors and exceptions
- Enabling floating-point traps

Containing Errors and Exceptions in Fortran DLLs

If you are building a Fortran DLL and intend to call it from a main program written in some other language, you want to be careful that errors and exceptions in the DLL do not crash your main application.

Here are a few basic principles to keep in mind if you are building a Fortran DLL:

- Construct your library routines so that they return a status to the caller and let the caller decide what to do.
- To return an expected status to the caller, you need to be defensive in your library code, so consider these other principles:
- Where it makes sense, have the library code check input arguments passed in from the caller to make sure they are valid for whatever the library routine is going to do with them. For example, suppose the routine implements some numerical algorithm that has a valid domain of inputs it can act on and still produce well defined behavior. You can check the input arguments before you execute the algorithm and avoid unexpected behavior that might otherwise result (like unexpected floating-point exceptions). You might use Fortran intrinsic procedures like ISNAN and FP_CLASS to detect exceptional IEEE numbers. Your DLL code needs to return a status to the caller indicating the problem and let the caller take the appropriate action (gracefully shut down the application, try again with different input, etc.).
- In your library code, *always* check the success or failure of calls to I/O routines and dynamic memory allocation/deallocation. In Fortran, the I/O statements have optional ERR, END, EOR, and IOSTAT arguments that you can use to determine if the I/O requested was successful. Dynamic memory ALLOCATE and DEALLOCATE statements have an optional STAT specifier that allows you to obtain the status of the dynamic memory allocation/deallocation and prevent program termination.
- If you do not specify an action to take on an error, the Fortran run-time system has no choice but to deal with the error as an unhandled severe error and terminate the program. For a specific example of using IOSTAT and ERR to deal gracefully with an OPEN statement that gets a file-not-found error, see Using the IOSTAT Specifier and Fortran Exit Codes. You can do the same sort of thing in your code, but just return the status back to your Visual Basic* or other non-Fortran main program and let it decide what to do.
- Try to write your DLL code so unexpected program exceptions cannot occur, but devise a strategy for dealing with unexpected exceptions if they do happen. The most effective alternative for dealing with an exception is to use Windows Structured Exception Handling support to gain control when an exception happens. Wrap all your DLL routine calls in C try/except constructs and have the `except()` filter expression call a routine you define which determines how to respond.

Enabling Floating-Point Traps in Fortran DLLs

Before you can worry about how you will handle a floating-point trap condition occurring in a DLL, you have to consider the problem of unmasking those traps so they can occur. If you are compiling with `fpe[:]3` and polling the floating-point status word to check for exceptions, you do not have to worry about the problem of unmasking traps. You do not want traps unmasked in that case.

If your strategy is to compile with `fpe[:]0` and allow traps on floating-point exceptions, you need to take action to unmask the traps in the floating-point control word because most other languages mask traps by default.

Recall that a Fortran Console or Fortran QuickWin (or Standard Graphics) application would have unmasked traps for you automatically because the Fortran run-time system provides the main program and calls your `MAIN__` which executes some prolog code before the actual application code starts. You do not have that in a Fortran DLL called by some other language. Different languages establish different initial environments. You must provide the desired initial environment yourself.

Custom Handlers for Fortran Windows* Applications

Fortran Windows* applications are not hooked up to the Fortran default exception handling processing facilities. Fortran Windows* applications are considered to be an area devoted to full customization, and the Fortran run-time system tries to "stay out of the way," so you can do whatever you want in your code.

Establishing Console Event Handlers

Control-C event handling is basically not reliable due to the threaded nature of processes executing on the Windows operating systems. Depending on what is happening at the instant a user types the Control-C, an event handler may or may not get the opportunity to execute. In any case, there are two ways to establish a handler if you want to do so. You can use the Windows* API routine `SetConsoleCtrlHandler` directly or you can use SIGNALQQ to establish a handler for the C `SIGINT` or `SIGBREAK` signals.

The Fortran run-time system establishes a console event handler through a call to `SetConsoleCtrlHandler` as part of its run-time initialization processing. See Default Console Event Handling for a description of this handler's behavior.

If you call `SetConsoleCtrlHandler` to establish your own event handler, your handler will be called first on console events.

If you establish a handler through SIGNALQQ with `SIGINT` or `SIGBREAK`, the C run-time system will establish its own internal handler for console events through a call to `SetConsoleCtrlHandler`, and it will record your routine as the desired action to take upon occurrence of an event. When an event is delivered to the C run-time handler, it will reset the action for the signal to `SIG_DFL` and then call your handler routine.

You must call SIGNALQQ again to reset the action to your routine if you want to continue from the control event. Your handler is called with the signal code (either `SIGINT` or `SIGBREAK`) as the argument. After your routine returns to the C run-time event handler, the C handler will return the value TRUE to the operating system indicating the event has been handled.

SIGNALQQ
Default Console Event Handling

Using SIGNALQQ

For lightweight exception handling requirements, a handler established with SIGNALQQ may meet your needs. This section describes how signal handling with SIGNALQQ works in detail and also how the Fortran run-time routine GETEXCEPTIONPTRSQQ works.

Reference is made to C run-time sources provided with Microsoft* Visual C++*. The discussion is worth reviewing even if you do not have Visual C++* available.

C-Style Signal Handling Overview

Many Fortran applications were developed on UNIX* systems where C-style signal handling was the usual way of dealing with exceptions. When ported to Windows*, these applications can continue to use the C signal interface. SIGNALQQ will work with any application type using pure Fortran or mixed Fortran and C code.

SIGNALQQ is just a Fortran jacket to the C run-time `signal()` function. When you call SIGNALQQ, you are actually registering your signal handler (or action) for a particular signal with the C run-time system. The C run-time system simply stores your handler (or action) in an internal exception action table or variable where it associates your handler with the desired signal. The operating system has no knowledge of this association.

If you have Visual C++* available, you can look at the code for the C run-time signal routine in `. . . \MICROSOFT VISUAL STUDIO .NET\VC7\CRT\SRC\WINSIG.C` and see how the table is managed. The table itself is defined and initialized in source file `WINXFLTR.C`, available in the same folder. When a signal occurs, the C run-time system checks its internal table to see if you have registered a handler for the particular signal. It calls your routine if you have assigned a handler.

Signal is Really SEH Again

Notice that it is the C run-time system that calls your handler when a signal occurs, not the operating system. So how did the C run-time get the exception delivered to it? Recall that the entry point of your image is either mainCRTStartup or WinMainCRTStartup, depending on the application type. Refer to Handlers for the Application (Project) Types and look at these entry points (or look at source file `Crt0.c` in the C run-time sources). Notice that they wrap a try-except construct around a call to either `main()` or `WinMain()` and that the filter expression associated with the __except construct calls a function `_XcptFilter`. `_XcptFilter` is passed two arguments which are the operating system supplied exception information.

When an exception occurs, the operating system looks at the list of exception filters and, starting with the inner-most nested try-except construct, evaluates except filter expressions until it finds one which does not return `EXCEPTION_CONTINUE_SEARCH`. If your application type includes main from the Fortran run-time system and thus the except construct associated with main, the Fortran run-time filter will be evaluated before the C run-time filter. The Fortran filter expression will check to see if you have established your own handler with SIGNALQQ. If it finds there is such a handler, or if you have set the environment variable `FOR_IGNORE_EXCEPTIONS`, it will return `EXCEPTION_CONTINUE_SEARCH` to allow the C run-time exception filter the opportunity to deal with the exception and find your handler. If you have not established your own handler or set the environment variable, the Fortran run-time will perform its default exception handling processing.

The C filter function, `_XcptFilter`, compares the exception code from the operating system with its mapping of operating system exceptions to C signal codes. If it finds a match in the table, it uses the exception action entry in the table corresponding to the signal code. This is the same table where your SIGNALQQ handler is recorded as the action for the requested signal code. If you have established a handler, it will be called from `_XcptFilter`. Before your handler is called, `_XcptFilter` resets the specified action for the signal to SIG_DFL in the exception action table. If you try to continue from the exception and you want your handler invoked on the next occurrence of the signal, you must call SIGNALQQ again to reestablish your handler as the action for that signal. When your handler routine is finished executing and returns to `_XcptFilter`, the value `EXCEPTION_CONTINUE_EXECUTION` is returned to the operating system by `_XcptFilter`. The operating system will then resume execution at the point of the exception. If you do not want to continue execution, your handler should take appropriate action to shut down the application.

Not every operating system exception code maps to a C signal code. You can see the mapping in source `WINXFLTR.C` if you have it. Here is the list if you do not have `WINXFLTR.C`:

Operating System Exception Code	C Signal Number
STATUS_ACCESS_VIOLATION	SIGSEGV
STATUS_ILLEGAL_INSTRUCTION	SIGILL
STATUS_PRIVILEGED_INSTRUCTION	SIGILL
STATUS_FLOAT_DENORMAL_OPERAND	SIGFPE
STATUS_FLOAT_DIVIDE_BY_ZERO	SIGFPE
STATUS_FLOAT_INEXACT_RESULT	SIGFPE
STATUS_FLOAT_INVALID_OPERATION	SIGFPE
STATUS_FLOAT_OVERFLOW	SIGFPE
STATUS_FLOAT_STACK_CHECK	SIGFPE
STATUS_FLOAT_UNDERFLOW	SIGFPE

How GETEXCEPTIONPTRSQQ Works

When the C run-time exception filter function `_XcptFilter` calls your handler that you established with SIGNALQQ, the only argument passed to your handler is the C signal number. The C run-time system also saves a pointer to the exception information supplied by the operating system. This pointer is named `_pxcptinfoptrs` and you can retrieve it through the Fortran run-time routine GETEXCEPTIONPTRSQQ (W*32). See C header file `signal.h` for the public definition of `_pxcptinfoptrs`.

The value returned by GETEXCEPTIONPTRSQQ can be used in your handler routine to generate a traceback with TRACEBACKQQ. GETEXCEPTIONPTRSQQ just returns `_pxcptinfoptrs`. This pointer is only valid while you are executing within the evaluation of the C run-time filter function `_XcptFilter` because the exception information is on the program stack, so do not use GETEXCEPTIONPTRSQQ in any other context.

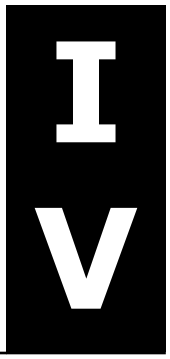
Part



Language Reference

This document contains the complete description of the Intel® Fortran programming language, which includes Fortran 2008, Fortran 2003, Fortran 95, Fortran 90, and some Fortran 2018 language features. It contains information on language syntax and semantics, on adherence to various Fortran standards, and on extensions to those standards.

For information about the Fortran standards, visit the Fortran standards technical committee website at http://j3-fortran.org/.

This manual is intended for experienced applications programmers who have a basic understanding of Fortran concepts and the Standard Fortran language.

Some familiarity with your operating system is helpful. This manual is not a Fortran or programming tutorial.

This document contains the following sections:

New Language Features	Describes the major new features for this release.
Program Elements and Source Forms	Describes program elements, the Fortran standard character set, and source forms.
Data Types, Constants, and Variables	Describes intrinsic and derived data types, constants, variables (scalars and arrays), and substrings.
Expressions and Assignment Statements	Summarizes Fortran expressions and assignment statements, which are used to define or redefine variables.
Specification Statements	Summarizes specification statements, which are used to declare the attributes of data objects.
Dynamic Allocation	Summarizes statements used in dynamic allocation: ALLOCATE, DEALLOCATE, and NULLIFY. It also describes the effects of allocation and deallocation.
Execution Control	Summarizes constructs and statements that can transfer control within a program.
Program Units and Procedures	Describes program units (including modules), subroutines and functions, and procedure interfaces.
Intrinsic Procedures	Describes argument keywords used in intrinsic procedures and provides an overview of intrinsic procedures.
Data Transfer I/O Statements	Summarizes data transfer input/output (I/O) statements.

I/O Formatting	Describes the rules for I/O formatting.
File Operation I/O Statements	Summarizes auxiliary I/O statements you can use to perform file operations.
Compilation Control Statements	Summarizes compilation control statements INCLUDE and OPTIONS.
Directive Enhanced Compilation	Describes general directives and OpenMP* Fortran compiler directives.
Scope and Association	Describes scope, which refers to the area in which a name is recognized, and association, which is the language concept that allows different names to refer to the same entity in a particular region of a program.
Deleted and Obsolescent Language Features	Describes deleted features in Fortran 2003 and obsolescent language features in Fortran 2003.
Additional Language Features	Describes some statements and language features supported for programs written in older versions of Fortran.
Additional Character Sets	Describes the additional character sets available on Windows*, Linux*, and macOS* systems.
Data Representation Models	Describes data representation models for numeric intrinsic functions.
Library Modules and Run-Time Library Routines	Summarizes the library modules and run-time library routines.
Summary of Language Extensions	Summarizes Intel Fortran extensions to the Fortran 2003 Standard.
A to Z Reference	Contains language summary tables and descriptions of all Intel® Fortran statements, intrinsics, directives, and module library routines, which are listed in alphabetical order.
Glossary	Contains abbreviated definitions of some commonly used terms in this manual.

Other books in this documentation set provide details about the features of the compilers, how to improve the run-time performance of Fortran programs, floating-point support, and compiler options.

For information on conventions used in this document, see Conventions.

For a summary of the latest Fortran 2003 features in this release, see Fortran 2003 Features.

For a summary of Fortran 2008 features in this release, see Fortran 2008 Features.

For a summary of Fortran 2018 features in this release, see Fortran 2018 Features.

New Language Features

The major new features for this release are as follows:

- Compiler option `assume [no]old_inquire_recl`

  Determines the value of the RECL= specifier on an INQUIRE statement for an unconnected unit or a unit connected for stream access. For more information, see assume.

- Compiler option `assume [no]old_ldout_zero`

  Determines the format of a floating-point zero produced by list-directed output. old_ldout_zero uses exponential format, noold_ldout_zero uses fractional format. For more information, see assume.
- Compiler option `check [no]udio_iostat`

  Determines whether standard conformance checking occurs when user defined derived type input/output procedures are executed. For more information, see check.
- Compiler option `warn [no]externals`

  Determines whether warnings occur for any dummy procedures or procedure calls that have on explicit interface or have not been declared EXTERNAL. For more information, see warn.

The following are new OpenMP* features:

- Extension to the OpenMP* SIMD directive

  You can now specify an IF clause for this directive. For more information, see SIMD Directive (OpenMP* API).
- Extension to the OpenMP* SIMD directive

  You can now specify a NONTEMPORAL clause for this directive. For more information, see SIMD Directive (OpenMP* API).
- The SCAN directive

  You can now specify the SCAN directive, which specifies a scan computation that updates each list item in each iteration of the loop the directive appears in. For more information, see SCAN.

For a summary of new Fortran 2018 features, see Fortran 2018 Features.

For a summary of new Fortran 2008 features, see Fortran 2008 Features.

For a summary of Fortran 2003 features, see Fortran 2003 Features.

For information on new compiler options in this release, see New Options in the *Compiler Options* reference.

For information about the Fortran standards, visit the Fortran standards technical committee website at http://j3-fortran.org/.

For information about the OpenMP* standards, see the OpenMP website at http://www.openmp.org/.

Program Elements and Source Forms

A Fortran program consists of one or more program units. A program unit is usually a sequence of statements that define the data environment and the steps necessary to perform calculations; it is terminated by an END statement.

A keyword in a Fortran program can either be a part of the syntax of a statement (statement keyword), or it can be the name of a dummy argument (argument keyword).

Names identify entities within a Fortran program unit. In earlier versions of Fortran, names were called "symbolic names".

Character sets show the characters you can use in Fortran programs.

Fortran programs can be in free, fixed, or tab format.

For more information, see the individual topics in this section.

Program Units

A Fortran program consists of one or more program units. A *program unit* is usually a sequence of statements that define the data environment and the steps necessary to perform calculations; it is terminated by an END statement.

A program unit can be either a main program, an external subprogram, a module, a submodule, or a block data program unit. An executable program contains one main program, and, optionally, any number of the other kinds of program units. Program units can be separately compiled.

An *external subprogram* is a function or subroutine that is not contained within a main program, a module, a submodule, or another subprogram. It defines a procedure to be performed and can be invoked from other program units of the Fortran program. Modules, submodules, and block data program units are not executable, so they are not considered to be procedures. (Modules and submodules can contain module procedures, though, which are executable.)

Modules contain definitions that can be made accessible to other program units: data and type definitions, definitions of procedures (called *module subprograms*), and *procedure interfaces*. Module subprograms can be either functions or subroutines. They can be invoked by other module subprograms in the module, or by other program units that access the module.

A *submodule* extends a module or another submodule. It can contain the definitions of procedures declared in a module or submodule.

A *block data program unit* specifies initial values for data objects in named common blocks. In Standard Fortran, this type of program unit can be replaced by a module program unit.

Main programs, external subprograms, and module subprograms can contain *internal subprograms*. The entity that contains the internal subprogram is its *host*. Internal subprograms can be invoked only by their host or by other internal subprograms in the same host. Internal subprograms must not contain internal subprograms.

The following sections discuss Statements, Names, and Keywords.

See Also

Program Units and Procedures

Statements

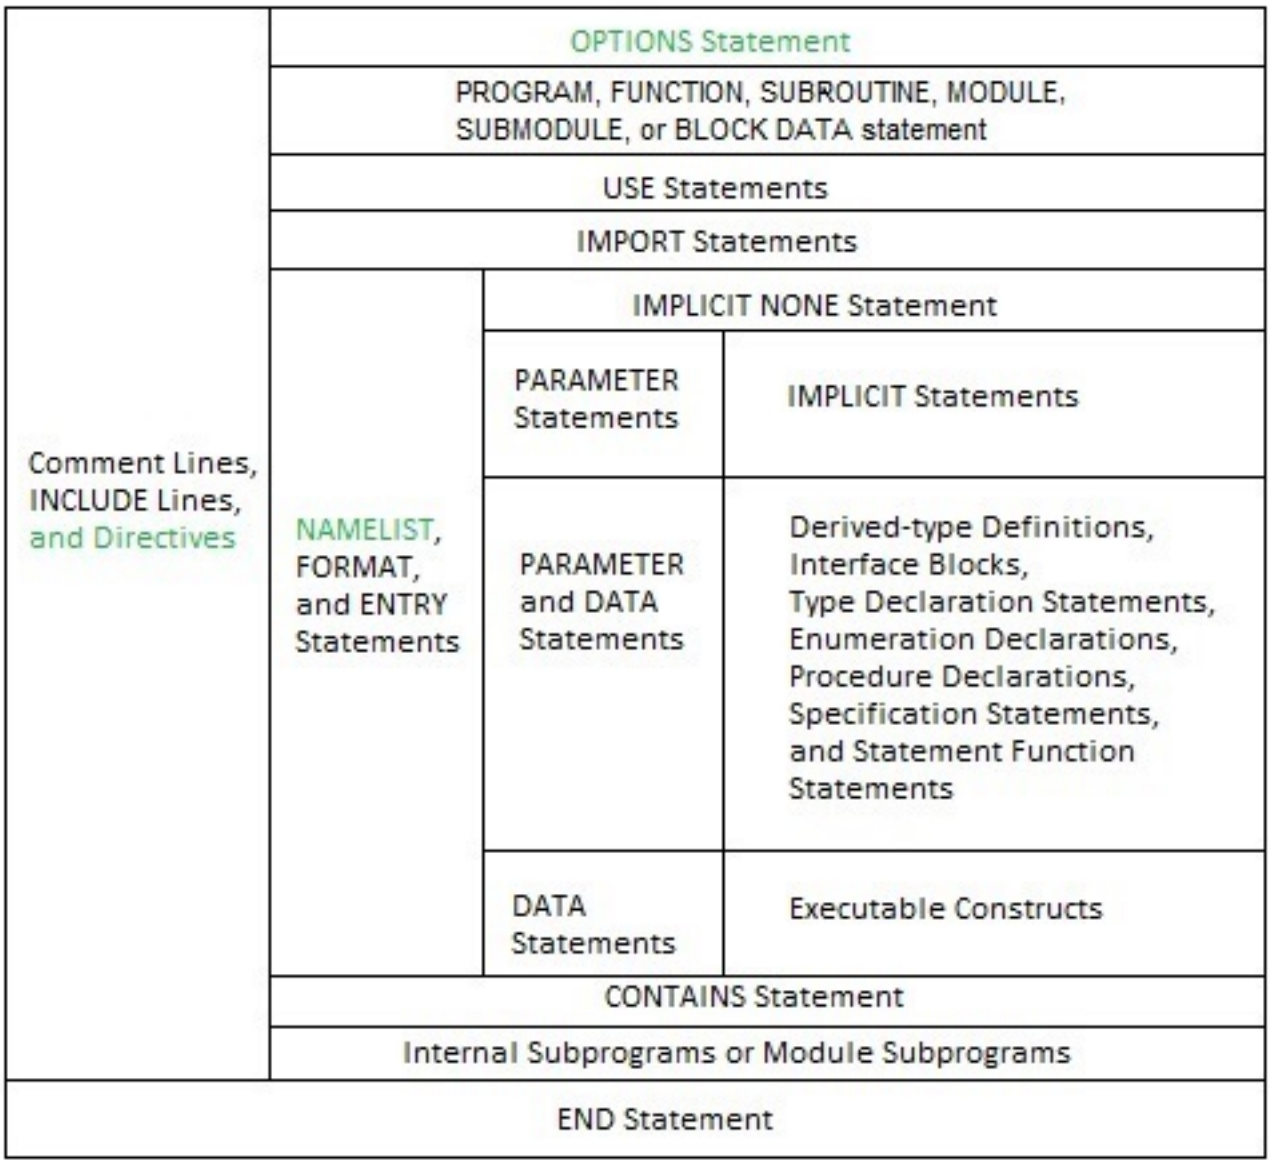
Program statements are grouped into two general classes: executable and nonexecutable. An *executable statement* specifies an action to be performed. A *nonexecutable statement* describes program attributes, such as the arrangement and characteristics of data, as well as editing and data-conversion information.

Order of Statements in a Program Unit

The following figure shows the required order of statements in a Fortran program unit. In this figure, vertical lines separate statement types that can be interspersed. For example, you can intersperse DATA statements with executable constructs.

Horizontal lines indicate statement types that cannot be interspersed. For example, you cannot intersperse DATA statements with CONTAINS statements.

Required Order of Statements



PUBLIC and PRIVATE statements are only allowed in the scoping units of modules. In Standard Fortran, NAMELIST statements can appear only among specification statements. However, Intel® Fortran allows them to also appear among executable statements.

The following table shows other statements restricted from different types of scoping units.

Statements Restricted in Scoping Units

Scoping Unit	Restricted Statements
Main program	ENTRY, IMPORT, and RETURN statements
Module[1]	ENTRY, FORMAT, IMPORT, OPTIONAL, and INTENT statements, statement functions, and executable statements

Scoping Unit	Restricted Statements
Submodule[1]	ENTRY, FORMAT, IMPORT, OPTIONAL, and INTENT statements, statement functions, and executable statements
Block data program unit	CONTAINS, ENTRY, IMPORT, and FORMAT statements, interface blocks, statement functions, and executable statements
Internal subprogram	CONTAINS, IMPORT, and ENTRY statements
Interface body	CONTAINS, DATA, ENTRY, IMPORT[2], SAVE, and FORMAT statements, statement functions, and executable statements
BLOCK construct	CONTAINS, DATA, ENTRY, and IMPORT statements, statement functions, and these specification statements: COMMON, EQUIVALENCE, IMPLICIT, INTENT (or its equivalent attribute), NAMELIST, OPTIONAL (or its equivalent attribute), and VALUE (or its equivalent attribute)

[1] The scoping unit of a module does not include any module subprograms that the module contains.

[2] An IMPORT statement can appear only in an interface body that is not a separate module procedure interface body.

See Also

Scope for details on scoping units

Keywords

A keyword can either be a part of the syntax of a statement (statement keyword), or it can be the name of a dummy argument (argument keyword). Examples of statement keywords are WRITE, INTEGER, DO, and OPEN. Examples of argument keywords are arguments to the intrinsic functions.

In the intrinsic function UNPACK (*vector*, *mask*, *field*), for example, *vector*, *mask*, and *field* are argument keywords. They are dummy argument names, and any variable may be substituted in their place. Dummy argument names and real argument names are discussed in topic Program Units and Procedures.

Keywords are not reserved. The compiler recognizes keywords by their context. For example, a program can have an array named IF, read, or Goto, even though this is not good programming practice. The only exception is the keyword PARAMETER. If you plan to use variable names beginning with PARAMETER in an assignment statement, you need to use compiler option altparam.

Using keyword names for variables makes programs harder to read and understand. For readability, and to reduce the possibility of hard-to-find bugs, avoid using names that look like parts of Fortran statements. Rules that describe the context in which a keyword is recognized are discussed in topic Program Units and Procedures.

Argument keywords are a feature of Standard Fortran that let you specify dummy argument names when calling intrinsic procedures, or anywhere an interface (either implicit or explicit) is defined. Using argument keywords can make a program more readable and easy to follow. This is described more fully in topic Program Units and Procedures. The syntax statements in the A-Z Reference show the dummy keywords you can use for each Fortran procedure.

See Also

altparam compiler option

Program Units and Procedures

Names

Names identify entities within a Fortran program unit (such as variables, function results, common blocks, named constants, procedures, program units, namelist groups, and dummy arguments). In FORTRAN 77, names were called "symbolic names".

A name can contain letters, digits, underscores (_), and the dollar sign ($) special character. The first character must be a letter or a dollar sign.

In Fortran 2008, a name can contain up to 63 characters.

The length of a module name (in MODULE and USE statements) may be restricted by your file system.

NOTE
Be careful when defining names that contain dollar signs. A dollar sign can be a symbol for command or symbol substitution in various shell and utility commands.

In an executable program, the names of the following entities are global and must be unique in the entire program:

- Program units
- External procedures
- Common blocks
- Modules

Examples

The following examples demonstrate valid and invalid names

Valid Names

```
NUMBER

FIND_IT

X
```

Invalid Names

`5Q`	Begins with a numeral.
`B.4`	Contains a special character other than _ or $.
`_WRONG`	Begins with an underscore.

The following are all valid examples of using names:

```
INTEGER (SHORT) K       !K names an integer variable
SUBROUTINE EXAMPLE      !EXAMPLE names the subroutine
LABEL: DO I = 1,N       !LABEL names the DO block
```

Character Sets

Intel® Fortran supports the following characters:

- The Fortran character set, which consists of the following:
  - All uppercase and lowercase letters (A through Z and a through z)
  - The numerals 0 through 9
  - The underscore (_)
  - The following special characters:

Character	Name	Character	Name
blank or <Tab>	Blank (space) or tab	;	Semicolon
=	Equal sign	!	Exclamation point
+	Plus sign	"	Quotation mark or quote
-	Minus sign	%	Percent sign
*	Asterisk	&	Ampersand
/	Slash	~	Tilde
\	Backslash	<	Less than
(	Left parenthesis	>	Greater than
)	Right parenthesis	?	Question mark
[	Left square bracket	'	Apostrophe
]	Right square bracket	`	Grave accent
{	Left curly bracket	^	Circumflex accent
}	Right curly bracket	|	Vertical line
,	Comma	$	Dollar sign (currency symbol)
.	Period or decimal point	#	Number sign
:	Colon	@	Commercial at

- Other printable characters

  Printable characters include the tab character (09 hex), ASCII characters with codes in the range 20(hex) through 7E(hex), and characters in certain special character sets.

  Printable characters that are not in the Standard Fortran character set can only appear in comments, character constants, Hollerith constants, character string edit descriptors, and input/output records.

Uppercase and lowercase letters are treated as equivalent when used to specify program behavior (except in character constants and Hollerith constants).

See Also

Data Types, Constants, and Variables for further details on character sets and default character types

ASCII and Key Code Charts for Windows*

ASCII Character Set for Linux* and macOS*

Source Forms

Within a program, source code can be in free, fixed, or tab form. Fixed or tab forms must not be mixed with free form in the same source program, but different source forms can be used in different source programs.

All source forms allow lowercase characters to be used as an alternative to uppercase characters.

Several characters are indicators in source code (unless they appear within a comment or a Hollerith or character constant). The following are rules for indicators in all source forms:

- Comment indicator

A comment indicator can precede the first statement of a program unit and appear anywhere within a program unit. If the comment indicator appears within a source line, the comment extends to the end of the line.

An all blank line is also a comment line.

Comments have no effect on the interpretation of the program unit.

For more information, see comment indicators in free source form, or fixed and tab source forms.

- Statement separator

  More than one statement (or partial statement) can appear on a single source line if a statement separator is placed between the statements. The statement separator is a semicolon character (;).

  Consecutive semicolons (with or without intervening blanks) are considered to be one semicolon.

  If a semicolon is the first character on a line, the last character on a line, or the last character before a comment, it is ignored.
- Continuation indicator

  A statement can be continued for more than one line by placing a continuation indicator on the line. Intel Fortran allows at least 511 continuation lines for a fixed or tab source program. Although Standard Fortran permits up to 256 continuation lines in free-form programs, Intel® Fortran allows up to 511 continuation lines.

  Comments can occur within a continued statement, but comment lines cannot be continued.

  For more information, see continuation indicators in free source form, or fixed and tab source forms.

The following table summarizes characters used as indicators in source forms.

Indicators in Source Forms

Source Item	Indicator [1]	Source Form	Position
Comment	!	All forms	Anywhere in source code
Comment line	!	Free	At the beginning of the source line
	!, C, or *	Fixed	In column 1
		Tab	In column 1
Continuation line [2]	&	Free	At the end of the source line
	Any character except zero or blank	Fixed	In column 6
	Any digit except zero	Tab	After the first tab
Statement separator	;	All forms	Between statements on the same line
Statement label	1 to 5 decimal digits	Free	Before a statement
		Fixed	In columns 1 through 5
		Tab	Before the first tab
A debugging statement[3]	D	Fixed	In column 1
		Tab	In column 1

Source Item	Indicator [1]	Source Form	Position

[1] If the character appears in a Hollerith or character constant, it is not an indicator and is ignored.

[2] For fixed or tab source form, at least 511 continuation lines are allowed. For free source form, at least 255 continuation lines are allowed.

[3] Fixed and tab forms only.

Source form and line length can be changed at any time by using the FREEFORM, NOFREEFORM, or FIXEDFORMLINESIZE directives. The change remains in effect until the end of the file, or until changed again.

You can also select free source form by using compiler option free.

Source code can be written so that it is useable for all source forms.

Statement Labels

A *statement label* (or statement number) identifies a statement so that other statements can refer to it, either to get information or to transfer control. A label can precede any statement that is not part of another statement.

A statement label must be one to five decimal digits long; blanks and leading zeros are ignored. An all-zero statement label is invalid, and a blank statement cannot be labeled.

Labeled FORMAT and labeled executable statements are the only statements that can be referred to by other statement. FORMAT statements are referred to only in the format specifier of an I/O statement or in an ASSIGN statement. Two statements within a scoping unit cannot have the same label.

See Also

free compiler option

Free Source Form

In free source form, statements are not limited to specific positions on a source line. In Standard Fortran, a free form source line can contain from 0 to 132 characters. Intel® Fortran allows the line to be of any length.

Blank characters are significant in free source form. The following are rules for blank characters:

- Blank characters must not appear in lexical tokens, except within a character context. For example, there can be no blanks between the exponentiation operator **. Blank characters can be used freely between lexical tokens to improve legibility.
- Blank characters must be used to separate names, constants, or labels from adjacent keywords, names, constants, or labels. For example, consider the following statements:

```
INTEGER NUM
GO TO 40
20 DO K=1,8
```

  The blanks are required after INTEGER, TO, 20, and DO.
- Some adjacent keywords must have one or more blank characters between them. Others do not require any; for example, BLOCK DATA can also be spelled BLOCKDATA. The following list shows which keywords have optional or required blanks:

Optional Blanks	Required Blanks
BLOCK DATA	ABSTRACT INTERFACE
DOUBLE COMPLEX	CASE DEFAULT
DOUBLE PRECISION	CLASS DEFAULT

Optional Blanks	Required Blanks
ELSE IF	CLASS IS
ELSE WHERE	DO CONCURRENT
END ASSOCIATE	DO WHILE
END BLOCK	ERROR STOP
END BLOCK DATA	EVENT POST
END CRITICAL	EVENT WAIT
END DO	FAIL IMAGE
END ENUM	IMPLICIT *type-specifier*
END FILE	IMPLICIT NONE
END FORALL	INTERFACE ASSIGNMENT
END FUNCTION	INTERFACE OPERATOR
END IF	MODULE PROCEDURE
END INTERFACE	*prefix*[1] [*prefix* ...] FUNCTION
END MODULE	*prefix*[1] [*prefix* ...] *type-specifier* [*prefix*...] FUNCTION
END PROCEDURE	*prefix*[1] [*prefix* ...] SUBROUTINE
END PROGRAM	SYNC ALL
END SELECT	SYNC IMAGES
END SUBMODULE	SYNC MEMORY
END SUBROUTINE	*type-specifier* FUNCTION
END TYPE	*type-specifier prefix*[1] [*prefix* ...] FUNCTION
END WHERE	
GO TO	
IN OUT	
SELECT CASE	
SELECT TYPE	

[1]*prefix* is ELEMENTAL or IMPURE or MODULE or NON_RECURSIVE or PURE or RECURSIVE. No *prefix* can be specified more than once. You cannot specify both IMPURE and PURE. You cannot specify both NON_RECURSIVE and RECURSIVE.

For information on statement separators (;) in all forms, see Source Forms.

Comment Indicator

In free source form, the exclamation point character (!) indicates a comment if it is within a source line, or a comment line if it is the first character in a source line.

Continuation Indicator

In free source form, the ampersand character (&) indicates a continuation line (unless it appears in a Hollerith or character constant, or within a comment). The continuation line is the first noncomment line following the ampersand. Although Standard Fortran permits up to 256 continuation lines in free-form programs, Intel® Fortran allows up to 511 continuation lines.

The following shows a continued statement:

```
TCOSH(Y) = EXP(Y) + &    ! The initial statement line
  EXP(-Y)                ! A continuation line
```

If the first nonblank character on the next noncomment line is an ampersand, the statement continues at the character following the ampersand. For example, the preceding example can be written as follows:

```
TCOSH(Y) = EXP(Y) + &
 & EXP(-Y)
```

If a lexical token must be continued, the first nonblank character on the next noncomment line must be an ampersand followed immediately by the rest of the token. For example:

```
   TCOSH(Y) = EXP(Y) + EX&
&P(-Y)
```

If you continue a character constant, an ampersand must be the first non-blank character of the continued line; the statement continues with the next character following the ampersand. For example:

```
ADVERTISER = "Davis, O'Brien, Chalmers & Peter&
        &son"
ARCHITECT  = "O'Connor, Emerson, and Dickinson&
      &  Associates"
```

If the ampersand is omitted on the continued line, the statement continues with the first non-blank character in the continued line. So, in the preceding example, the whitespace before "Associates" would be ignored.

The ampersand cannot be the only nonblank character in a line, or the only nonblank character before a comment; an ampersand in a comment is ignored.

See Also

Source Forms for details on the general rules for all source forms

Fixed and Tab Source Forms

In the Fortran standard, fixed source form is identified as obsolescent.

In fixed and tab source forms, there are restrictions on where a statement can appear within a line.

By default, a statement can extend to character position 72. In this case, any text following position 72 is ignored and no warning message is printed. You can specify compiler option extend-source to extend source lines to character position 132.

Except in a character context, blanks are not significant and can be used freely throughout the program for maximum legibility.

Some Fortran compilers use blanks to pad short source lines out to 72 characters. By default, Intel® Fortran does not. If portability is a concern, you can use the concatenation operator to prevent source lines from being padded by other Fortran compilers (see the example in "Continuation Indicator" below) or you can force short source lines to be padded by using compiler option pad-source.

Comment Indicator

In fixed and tab source forms, the exclamation point character (!) indicates a comment if it is within a source line. It must not appear in column 6 of a fixed form line; that column is reserved for a continuation indicator.

The letter C (or c), an asterisk (*), or an exclamation point (!) indicates a comment line when it appears in column 1 of a source line.

Continuation Indicator

In fixed and tab source forms, a continuation line is indicated by one of the following:

- For fixed form: Any character (except a zero or blank) in column 6 of a source line
- For tab form: Any digit (except zero) after the first tab

The compiler considers the characters following the continuation indicator to be part of the previous line. Although Standard Fortran permits up to 19 continuation lines in a fixed-form program, Intel® Fortran allows up to 511 continuation lines.

If a zero or blank is used as a continuation indicator, the compiler considers the line to be an initial line of a Fortran statement.

The statement label field of a continuation line must be blank (except in the case of a debugging statement).

When long character or Hollerith constants are continued across lines, portability problems can occur. Use the concatenation operator to avoid such problems. For example:

```
      PRINT *, 'This is a very long character constant '//
     +         'which is safely continued across lines'
```

Use this same method when initializing data with long character or Hollerith constants. For example:

```
      CHARACTER*(*) LONG_CONST
      PARAMETER (LONG_CONST = 'This is a very long '//
     + 'character constant which is safely continued '//
     + 'across lines')
      CHARACTER*100 LONG_VAL
      DATA LONG_VAL /LONG_CONST/
```

Hollerith constants must be converted to character constants before using the concatenation method of line continuation.

The Fortran Standard requires that, within a program unit, the END statement cannot be continued, and no other statement in the program unit can have an initial line that appears to be the program unit END statement. In these instances, Intel Fortran produces warnings when standards checking is requested.

Debugging Statement Indicator

In fixed and tab source forms, the statement label field can contain a statement label, a comment indicator, or a debugging statement indicator.

The letter D indicates a debugging statement when it appears in column 1 of a source line. The initial line of the debugging statement can contain a statement label in the remaining columns of the statement label field.

If a debugging statement is continued onto more than one line, every continuation line must begin with a D and a continuation indicator.

By default, the compiler treats debugging statements as comments. However, you can specify compiler option d-lines to force the compiler to treat debugging statements as source text to be compiled.

Fixed-format lines
Tab-format lines
Source Forms for details on the general rules for all source forms
d-lines compiler option
extend-source compiler option
pad-source compiler option

Fixed-Format Lines

In fixed source form, a source line has columns divided into fields for statement labels, continuation indicators, statement text, and sequence numbers. Each column represents a single character.

The column positions for each field follow:

Field	Column
Statement label	1 through 5
Continuation indicator	6
Statement	7 through 72 (or 132 with compiler option extend-source)
Sequence number	73 through 80

By default, a sequence number or other identifying information can appear in columns 73 through 80 of any fixed-format line in an Intel® Fortran program. The compiler ignores the characters in this field.

If you extend the statement field to position 132, the sequence number field does not exist.

> **NOTE**
> If you use the sequence number field, do not use tabs anywhere in the source line, or the compiler may interpret the sequence numbers as part of the statement field in your program.

See Also

Source Forms
Fixed and Tab Source Forms
extend-source compiler option

Tab-Format Lines

In tab source form, you can specify a statement label field, a continuation indicator field, and a statement field, but not a sequence number field.

The following figure shows equivalent source lines coded with tab and fixed source form.

Line Formatting Example

Format using TAB Character

C TAB FIRST VALUE

10 TAB I = J + 5*K +

TAB 1 L*M

TAB IVAL = I+2

Character-per-Column Format

1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17	18	19	20
C						F	I	R	S	T		V	A	L	U	E			
1	0					I		=		J		+		5	*	K		+	
					1		L	*	M										
						I	V	A	L		=	I	+	2					

ZK-0614-GE

The statement label field precedes the first tab character. The continuation indicator field and statement field follow the first tab character.

The continuation indicator is any nonzero digit. The statement field can contain any Fortran statement. A Fortran statement cannot start with a digit.

If a statement is continued, a continuation indicator must be the first character (following the first tab) on the continuation line.

Many text editors and terminals advance the terminal print carriage to a predefined print position when you press the <Tab> key. However, the Intel® Fortran compiler does not interpret the tab character in this way. It treats the tab character in a statement field the same way it treats a blank character. In the source listing that the compiler produces, the tab causes the character that follows to be printed at the next tab stop (usually located at columns 9, 17, 25, 33, and so on).

NOTE
If you use the sequence number field, do not use tabs anywhere in the source line, or the compiler may interpret the sequence numbers as part of the statement field in your program.

Source Forms for details on the general rules for all source forms
Fixed and Tab Source Forms for details on the general rules for fixed and tab source forms

Source Code Useable for All Source Forms

To write source code that is useable for all source forms (free, fixed, or tab), follow these rules:

Blanks	Treat as significant (see Free Source Form).

Statement labels	Place in column positions 1 through 5 (or before the first tab character).
Statements	Start in column position 7 (or after the first tab character).
Comment indicator	Use only !. Place anywhere *except* in column position 6 (or immediately after the first tab character).
Continuation indicator	Use only &. Place in column position 73 of the initial line and each continuation line, and in column 6 of each continuation line (no tab character can precede the ampersand in column 6).

The following example is valid for all source forms:

```
Column:
12345678...
                                                                      73
_______________________________________________________________________

! Define the user function MY_SIN
      DOUBLE PRECISION FUNCTION MY_SIN(X)
        MY_SIN = X - X**3/FACTOR(3) + X**5/FACTOR(5)                    &
     &           - X**7/FACTOR(7)
      CONTAINS
        INTEGER FUNCTION FACTOR(N)
         FACTOR = 1
         DO 10 I = N, 1, -1
  10     FACTOR = FACTOR * I
        END FUNCTION FACTOR
      END FUNCTION MY_SIN
```

Data Types, Constants, and Variables

Each constant, variable, array, expression, or function reference in a Fortran statement has a data type. The data type of these items can be inherent in their construction, implied by convention, or explicitly declared.

Each *data type* has the following properties:

- A name

  The names of the intrinsic data types are predefined, while the names of derived types are defined in derived-type definitions. Data objects (constants, variables, or parts of constants or variables) are declared using the name of the data type.
- A set of associated values

  Each data type has a set of valid values. Integer and real data types have a range of valid values. Complex and derived types have sets of values that are combinations of the values of their individual components.
- A way to represent constant values for the data type

  A *constant* is a data object with a fixed value that cannot be changed during program execution. The value of a constant can be a numeric value, a logical value, or a character string.

  A constant that does not have a name is a *literal constant*. A literal constant must be of intrinsic type and it cannot be array-valued.

A constant that has a name is a *named constant*. A named constant can be of any type, including derived type, and it can be array-valued. A named constant has the PARAMETER attribute and is specified in a type declaration statement or PARAMETER statement.

- A set of operations to manipulate and interpret these values

  The data type of a variable determines the operations that can be used to manipulate it. Besides intrinsic operators and operations, you can also define operators and operations.

Expressions for details on valid operations for data types

Intrinsic Data Types

Intel® Fortran provides the following intrinsic data types:

- INTEGER

  The following kind parameters are available for data of type integer:

  - INTEGER([KIND=]1) or INTEGER*1
  - INTEGER([KIND=]2) or INTEGER*2
  - INTEGER([KIND=]4) or INTEGER*4
  - INTEGER([KIND=]8) or INTEGER*8
- REAL

  The following kind parameters are available for data of type real:

  - REAL([KIND=]4) or REAL*4
  - REAL([KIND=]8) or REAL*8
  - REAL([KIND=]16) or REAL*16
- DOUBLE PRECISION

  No kind parameter is permitted for data declared with type DOUBLE PRECISION. This data type is the same as REAL([KIND=]8).
- COMPLEX

  The following kind parameters are available for data of type complex:

  - COMPLEX([KIND=]4) or COMPLEX*8
  - COMPLEX([KIND=]8) or COMPLEX*16
  - COMPLEX([KIND=]16) or COMPLEX*32
- DOUBLE COMPLEX

  No kind parameter is permitted for data declared with type DOUBLE COMPLEX. This data type is the same as COMPLEX([KIND=]8).
- LOGICAL

  The following kind parameters are available for data of type logical:

  - LOGICAL([KIND=]1) or LOGICAL*1
  - LOGICAL([KIND=]2) or LOGICAL*2
  - LOGICAL([KIND=]4) or LOGICAL*4
  - LOGICAL([KIND=]8) or LOGICAL*8
- CHARACTER

  There is one kind parameter available for data of type character: CHARACTER([KIND=]1).
- BYTE

  This is a 1-byte value; the data type is equivalent to INTEGER([KIND=]1).

The intrinsic function KIND can be used to determine the kind type parameter of a representation method.

For more portable programs, you should not use the forms INTEGER([KIND=]n) or REAL([KIND=]n). You should instead define a PARAMETER constant using the SELECTED_INT_KIND or SELECTED_REAL_KIND function, whichever is appropriate. For example, the following statements define a PARAMETER constant for an INTEGER kind that has 9 digits:

```
INTEGER, PARAMETER :: MY_INT_KIND = SELECTED_INT_KIND(9)
  ...
INTEGER(MY_INT_KIND) :: J
  ...
```

Note that the syntax :: is used in type declaration statements.

The following sections describe the intrinsic data types and forms for literal constants for each type.

See Also

KIND intrinsic function

Declaration Statements for Noncharacter Types for details on declaration statements for intrinsic data types

Declaration Statements for Character Types for details on declaration statements for intrinsic data types

Expressions for details on operations for intrinsic data types

Data Type Storage Requirements table for details on storage requirements for intrinsic data types

Integer Data Types

Integer data types can be specified as follows:

INTEGER

INTEGER([KIND=]*n*)

INTEGER**n*

n	Is a constant expression that evaluates to kind 1, 2, 4, or 8.

If a kind parameter is specified, the integer has the kind specified. If a kind parameter is not specified, integer constants are interpreted as follows:

- If the integer constant is within the default integer kind range, the kind is default integer.
- If the integer constant is outside the default integer kind range, the kind of the integer constant is the smallest integer kind that holds the constant.

Default integer is affected by compiler option integer-size, the INTEGER compiler directive, and the OPTIONS statement.

The intrinsic inquiry function KIND returns the kind type parameter, if you do not know it. You can use the intrinsic function SELECTED_INT_KIND to find the kind values that provide a given range of integer values. The decimal exponent range is returned by the intrinsic function RANGE.

Examples

The following examples show ways an integer variable can be declared.

An entity-oriented example is:

```
INTEGER, DIMENSION(:), POINTER :: days, hours
INTEGER(2), POINTER :: k, limit
INTEGER(1), DIMENSION(10) :: min
```

An attribute-oriented example is:

```
INTEGER days, hours
INTEGER(2) k, limit
INTEGER(1) min
DIMENSION days(:), hours(:), min (10)
POINTER days, hours, k, limit
```

An integer can be used in certain cases when a logical value is expected, such as in a logical expression evaluating a condition, as in the following:

```
INTEGER I, X
READ (*,*) I
IF (I) THEN
  X = 1
END IF
```

Integer Constants
integer-size compiler option

Integer Constants

An *integer constant* is a whole number with no decimal point. It can have a leading sign and is interpreted as a decimal number.

Integer constants take the following form:

[*s*]*n*[*n*...][_*k*]

s	Is a sign; required if negative (-), optional if positive (+).
n	Is a decimal digit (0 through 9). Any leading zeros are ignored.
k	Is the optional kind parameter: 1 for INTEGER(1), 2 for INTEGER(2), 4 for INTEGER(4), or 8 for INTEGER(8). It must be preceded by an underscore (_).

An unsigned constant is assumed to be nonnegative.

Integer constants are interpreted as decimal values (base 10) by default. To specify a constant that is not in base 10, use the following extension syntax:

[*s*] [[*base*] #] *nnn*...

s	Is an optional plus (+) or minus (-) sign.
base	Is any constant from 2 through 36. If *base* is omitted but # is specified, the integer is interpreted in base 16. If both *base* and # are omitted, the integer is interpreted in base 10. For bases 11 through 36, the letters A through Z represent numbers greater than 9. For example, for base 36, A represents 10, B represents 11, C represents 12, and so on, through Z, which represents 35. The case of the letters is not significant. The value of *nnn* cannot be bigger than 2**31-1. The value is extended with zeroes on the left or truncated on the left to make it the correct size. A minus sign for *s* negates the value.

Note that compiler option `integer-size` can affect the KIND type parameter of INTEGER data and integer constants.

Examples

Valid Integer (base 10) Constants

0
-127
+32123
47_2

Invalid Integer (base 10) Constants

9999999999999999999	Number too large.
3.14	Decimal point not allowed; this is a valid REAL constant.
32,767	Comma not allowed.
33_3	3 is not a valid kind type for integers.

The following seven integers are all assigned a value equal to 3,994,575 decimal:

```
I = 2#11110011111001111001111
m = 7#45644664
J = +8#17171717
K = #3CF3CF
n = +17#2DE110
L = 3994575
index = 36#2DM8F
```

The following seven integers are all assigned a value equal to -3,994,575 decimal:

```
I = -2#11110011111001111001111
m = -7#45644664
J = -8#17171717
K = -#3CF3CF
n = -17#2DE110
L = -3994575
index = -36#2DM8F
```

You can use integer constants to assign values to data. The following table shows assignments to different data and lists the integer and hexadecimal values in the data:

```
Fortran Assignment     Integer Value in Data    Hexadecimal Value in Data

LOGICAL(1)X
INTEGER(1)X
X = -128                         -128                Z'80'
X =  127                          127                Z'7F'
X =  255                           -1                Z'FF'

LOGICAL(2)X
INTEGER(2)X
X = 255                           255                Z'FF'
X = -32768                     -32768                Z'8000'
X = 32767                       32767                Z'7FFF'
X = 65535                          -1                Z'FFFF'
```

Numeric Expressions
integer-size compiler option

Real Data Types

Real data types can be specified as follows:

REAL

REAL([KIND=]*n*)

REAL**n*

DOUBLE PRECISION

n	Is a constant expression that evaluates to kind 4, 8, or 16.

If a kind parameter is specified, the real constant has the kind specified. If a kind parameter is not specified, the kind is default real.

Default real is affected by compiler options specifying real size and by the REAL directive.

The default KIND for DOUBLE PRECISION is affected by compiler option double-size. If this compiler option is not specified, default DOUBLE PRECISION is REAL(8).

No kind parameter is permitted for data declared with type DOUBLE PRECISION.

The intrinsic inquiry function KIND returns the kind type parameter. The intrinsic inquiry function RANGE returns the decimal exponent range, and the intrinsic function PRECISION returns the decimal precision. You can use the intrinsic function SELECTED_REAL_KIND to find the kind values that provide a given precision and exponent range.

Examples

The following examples show how real variables can be declared.

An entity-oriented example is:

```
REAL (KIND = high), OPTIONAL :: testval
REAL, SAVE :: a(10), b(20,30)
```

An attribute-oriented example is:

```
REAL (KIND = high) testval
REAL a(10), b(20,30)
OPTIONAL testval
SAVE a, b
```

REAL(16) Constants
real-size

General Rules for Real Constants

A *real constant* approximates the value of a mathematical real number. The value of the constant can be positive, zero, or negative.

The following is the general form of a real constant with no exponent part:

[*s*]*n*[*n*...][_*k*]

A real constant with an exponent part has one of the following forms:

[*s*]*n*[*n*...]E[*s*]*nn*...[_*k*]

[*s*]*n*[*n*...]D[*s*]*nn*...

[*s*]*n*[*n*...]Q[*s*]*nn*...

s	Is a sign; required if negative (-), optional if positive (+).
n	Is a decimal digit (0 through 9). A decimal point must appear if the real constant has no exponent part.
k	Is the optional kind parameter: 4 for REAL(4), 8 for REAL(8), or 16 for REAL(16). It must be preceded by an underscore (_).

Description

Leading zeros (zeros to the left of the first nonzero digit) are ignored in counting significant digits. For example, in the constant 0.00001234567, all of the nonzero digits, and none of the zeros, are significant. (See the following sections for the number of significant digits each kind type parameter typically has).

The exponent represents a power of 10 by which the preceding real or integer constant is to be multiplied (for example, 1.0E6 represents the value 1.0 * 10**6).

A real constant with no exponent part and no kind type parameter is (by default) a single-precision (REAL(4)) constant. You can change the default behavior by specifying compiler option fpconstant.

If the real constant has no exponent part, a decimal point must appear in the string (anywhere before the optional kind parameter). If there is an exponent part, a decimal point is optional in the string preceding the exponent part; the exponent part must not contain a decimal point.

The exponent letter E denotes a single-precision real (REAL(4)) constant, unless the optional kind parameter specifies otherwise. For example, -9.E2_8 is a double-precision constant (which can also be written as -9.D2).

The exponent letter D denotes a double-precision real (REAL(8)) constant.

The exponent letter Q denotes a quad-precision real (REAL(16)) constant.

A minus sign must appear before a negative real constant; a plus sign is optional before a positive constant. Similarly, a minus sign must appear between the exponent letter (E, D, or Q) and a negative exponent, whereas a plus sign is optional between the exponent letter and a positive exponent.

If the real constant includes an exponent letter, the exponent field cannot be omitted, but it can be zero.

To specify a real constant using both an exponent letter and a kind parameter, the exponent letter must be E, and the kind parameter must follow the exponent part.

See Also

fpconstant compiler option

REAL(4) Constants

A single-precision REAL constant occupies four bytes of memory. The number of digits is unlimited, but typically only the leftmost seven digits are significant.

IEEE* IEEE binary32 format is used.

Note that compiler option real-size can affect REAL data.

Examples

Valid REAL(4) Constants

```
3.14159

3.14159_4
```

```
621712._4

-.00127

+5.0E3

2E-3_4
```

Invalid REAL(4) Constants

`1,234,567.`	Commas not allowed.
`325E-47`	Too small for REAL; this is a valid DOUBLE PRECISION constant.
`-47.E47`	Too large for REAL; this is a valid DOUBLE PRECISION constant.
`625._6`	6 is not a valid kind for reals.
`100`	Decimal point is missing; this is a valid integer constant.
`$25.00`	Special character not allowed.

real-size compiler option

Compiler Reference > Data and I/O section: *Data Representation*

REAL(8) or DOUBLE PRECISION Constants

A REAL(8) or DOUBLE PRECISION constant has more than twice the accuracy of a REAL(4) number, and greater range.

A REAL(8) or DOUBLE PRECISION constant occupies eight bytes of memory. The number of digits that precede the exponent is unlimited, but typically only the leftmost 15 digits are significant.

IEEE* binary64 format is used.

Note that compiler option double-size can affect DOUBLE PRECISION data.

The default KIND for DOUBLE PRECISION is affected by compiler option double-size.

Examples

Valid REAL(8) or DOUBLE PRECISION Constants

```
123456789D+5

123456789E+5_8

+2.7843D00

-.522D-12

2E200_8

2.3_8

3.4E7_8
```

Invalid REAL(8) or DOUBLE PRECISION Constants

`-.25D0_2`	2 is not a valid kind for reals.
`+2.7182812846182`	No D exponent designator is present; this is a valid single-precision constant.
`123456789.D400`	Too large for any double-precision format.
`123456789.D-400`	Too small for any double-precision format.

See Also

General Rules for Real Constants

double-size compiler option

Compiler Reference > Data and I/O section: *Data Representation*

REAL(16) Constants

A REAL(16) constant has more than four times the accuracy of a REAL(4) number, and a greater range.

A REAL(16) constant occupies 16 bytes of memory. The number of digits that precede the exponent is unlimited, but typically only the leftmost 33 digits are significant.

IEEE* binary128 format is used.

Examples

Valid REAL(16) Constants

```
123456789Q4000

-1.23Q-400

+2.72Q0

1.88_16
```

Invalid REAL(16) Constants

`1.Q5000`	Too large.
`1.Q-5000`	Too small.

General Rules for Real Constants

Compiler Reference > Data and I/O section: *Data Representation*

Complex Data Types

Complex data types can be specified as follows:

COMPLEX

COMPLEX([KIND=]*n*)

COMPLEX**s*

DOUBLE COMPLEX

n	Is a constant expression that evaluates to kind 4, 8, or 16.

s	Is 8, 16, or 32. COMPLEX(4) is specified as COMPLEX*8; COMPLEX(8) is specified as COMPLEX*16; COMPLEX(16) is specified as COMPLEX*32.

If a kind parameter is specified, the complex constant has the kind specified. If no kind parameter is specified, the kind of both parts is default real, and the constant is of type default complex.

Default real is affected by compiler option real-size and by the REAL directive.

The default KIND for DOUBLE COMPLEX is affected by compiler option `double-size`. If the compiler option is not specified, default DOUBLE COMPLEX is COMPLEX(8).

No kind parameter is permitted for data declared with type DOUBLE COMPLEX.

A complex number of any kind is made up of a real part and an imaginary part. The REAL and AIMAG intrinsic functions return the real and imaginary parts of a complex number respectively. The CMPLX intrinsic constructs a complex number from two real numbers. The %re and %im complex part designators access the real and imaginary parts of a complex number respectively.

Examples

The following examples show how complex variables can be declared.

An entity-oriented example is:

```
COMPLEX (4), DIMENSION (8) :: cz, cq
```

An attribute-oriented example is:

```
COMPLEX(4) cz, cq
DIMENSION(8) cz, cq
```

The following shows an example of the parts of a complex number:

```
COMPLEX (4) :: ca = (1.0, 2.0)
REAL (4) :: ra = 3.0, rb = 4.0
PRINT *, REAL (ca), ca%RE            ! prints 1.0, 1.0
PRINT *, AIMAG (ca), ca%IM           ! prints 2.0, 2.0
PRINT *, CMPLX (ra, rb)              ! prints (3.0, 4.0)
ca = CMPLX (ra, AIMAG (ca))
PRINT *, ca                          ! prints (3.0, 2.0)
ca%im = rb
PRINT *, ca                          ! prints (3.0, 4.0)
```

CMPLX intrinsic
COMPLEX(4) Constants
COMPLEX(8) or DOUBLE COMPLEX Constants
REAL intrinsic

General Rules for Complex Constants

A *complex constant* approximates the value of a mathematical complex number. The constant is a pair of real or integer values, separated by a comma, and enclosed in parentheses. The first constant represents the real part of that number; the second constant represents the imaginary part.

The following is the general form of a complex constant:

(*c*,*c*)

c	Is as follows:

- For COMPLEX(4) constants, *c* is an integer or REAL(4) constant.
- For COMPLEX(8) constants, *c* is an integer, REAL(4) constant, or DOUBLE PRECISION (REAL(8)) constant. At least one of the pair must be DOUBLE PRECISION.
- For COMPLEX(16) constants, *c* is an integer, REAL(4) constant, REAL(8) constant, or REAL(16) constant. At least one of the pair must be a REAL(16) constant.

Note that the comma and parentheses are required.

COMPLEX(4) Constants

A COMPLEX(4) constant is a pair of integer or single-precision real constants that represent a complex number.

A COMPLEX(4) constant occupies eight bytes of memory and is interpreted as a complex number.

If the real and imaginary part of a complex literal constant are both real, the kind parameter value is that of the part with the greater decimal precision.

The rules for REAL(4) constants apply to REAL(4) constants used in COMPLEX constants. (See General Rules for Complex Constants and REAL(4) Constants for the rules on forming REAL(4) constants.)

The REAL(4) constants in a COMPLEX constant have IEEE* binary32 format.

Note that compiler option real-size can affect REAL data.

Examples

Valid COMPLEX(4) Constants

```
(1.7039,-1.70391)

(44.36_4,-12.2E16_4)

(+12739E3,0.)

(1,2)
```

Invalid COMPLEX(4) Constants

`(1.23,)`	Missing second integer or single-precision real constant.
`(1.0, 2H12)`	Hollerith constant not allowed.

See Also

General Rules for Complex Constants
real-size compiler option

COMPLEX(8) or DOUBLE COMPLEX Constants

A COMPLEX(8) or DOUBLE COMPLEX constant is a pair of constants that represents a complex number. One of the pair must be a double-precision real constant, the other can be an integer, single-precision real, or double-precision real constant.

A COMPLEX(8) or DOUBLE COMPLEX constant occupies 16 bytes of memory and is interpreted as a complex number.

The rules for DOUBLE PRECISION (REAL(8)) constants also apply to the double precision portion of COMPLEX(8) or DOUBLE COMPLEX constants. (See General Rules for Complex Constants and REAL(8) or DOUBLE PRECISION Constants for the rules on forming DOUBLE PRECISION constants.)

The DOUBLE PRECISION constants in a COMPLEX(8) or DOUBLE COMPLEX constant have IEEE* binary64 format.

The default KIND for DOUBLE COMPLEX is affected by compiler option `double-size`.

Examples

Valid COMPLEX(8) or DOUBLE COMPLEX Constants

```
(1.7039,-1.7039D0)

(547.3E0_8,-1.44_8)

(1.7039E0,-1.7039D0)

(+12739D3,0.D0)
```

Invalid COMPLEX(8) or DOUBLE COMPLEX Constants

`(1.23D0,)`	Second constant missing.
`(1D1,2H12)`	Hollerith constants not allowed.
`(1,1.2)`	Neither constant is DOUBLE PRECISION; this is a valid single-precision constant.

General Rules for Complex Constants
double-size

COMPLEX(16) Constants

A COMPLEX(16) constant is a pair of constants that represents a complex number. One of the pair must be a REAL(16) constant, the other can be an integer, single-precision real, double-precision real, or REAL(16) constant.

A COMPLEX(16) constant occupies 32 bytes of memory and is interpreted as a complex number.

The rules for REAL(16) constants apply to REAL(16) constants used in COMPLEX constants. (See General Rules for Complex Constants and REAL(16) Constants for the rules on forming REAL(16) constants.)

The REAL(16) constants in a COMPLEX constant have IEEE* binary128 format.

Note that compiler option real-size can affect REAL data.

Examples

Valid COMPLEX(16) Constants

```
(1.7039,-1.7039Q2)

(547.3E0_16,-1.44)

(+12739D3,0.Q0)
```

Invalid COMPLEX(16) Constants

`(1.23Q0,)`	Second constant missing.
`(1D1,2H12)`	Hollerith constants not allowed.
`(1.7039E0,-1.7039D0)`	Neither constant is REAL(16); this is a valid double-precision constant.

General Rules for Complex Constants

real-size compiler option

Logical Data Types

Logical data types can be specified as follows:

LOGICAL

LOGICAL([KIND=]*n*)

LOGICAL*_n_

n	Is a constant expression that evaluates to kind 1, 2, 4, or 8.

If a kind parameter is specified, the logical constant has the kind specified. If no kind parameter is specified, the kind of the constant is default logical.

Examples

The following examples show how logical variables can be declared.

An entity-oriented example is:

```
LOGICAL, ALLOCATABLE :: flag1, flag2
LOGICAL (KIND = byte), SAVE :: doit, dont
```

An attribute-oriented example is:

```
LOGICAL flag1, flag2
LOGICAL (KIND = byte) doit, dont
ALLOCATABLE flag1, flag2
SAVE doit, dont
```

See Also

Logical Constants

Logical Constants

A logical constant represents only the logical values true or false, and takes one of the following forms:

.TRUE.[_*k*]

.FALSE.[_*k*]

k	Is the optional kind parameter: 1 for LOGICAL(1), 2 for LOGICAL(2), 4 for LOGICAL(4), or 8 for LOGICAL(8). It must be preceded by an underscore (_).

The numeric value of .TRUE. and .FALSE. can be -1 and 0 or 1 and 0 depending on compiler option fpscomp [no]logicals. Logical data can take on integer data values. Logical data type ranges correspond to their comparable integer data type ranges. For example, the LOGICAL(2) range is the same as the INTEGER(2) range.

Character Data Type

The character data type can be specified as follows:

CHARACTER ([LEN=] *len*)

CHARACTER (LEN= *len*, KIND= *n*)

CHARACTER (len, [KIND=] *n*)

CHARACTER (KIND= *n* [, LEN= *len*])

CHARACTER* *len* [,]

n	Is a constant expression that evaluates to kind 1.
len	Is a string length (not a kind). For more information, see Declaration Statements for Character Types.

If no kind type parameter is specified, the kind of the constant is default character.

On Windows systems, several Multi-Byte Character Set (MBCS) functions are available to manipulate special non-English characters.

Character Data Type

Character Constants

A *character constant* is a character string enclosed in delimiters (apostrophes or quotation marks). It takes one of the following forms:

[*k*_]'[*ch*...]' [*C*]

[*k*_]"[*ch*...]" [*C*]

k	Is the optional kind parameter: 1 (the default). It must be followed by an underscore (_). Note that in character constants, the kind must precede the constant.
ch	Is an ASCII character.
C	Is a C string specifier. C strings can be used to define NUL-terminated strings. For more information, see C Strings in Character Constants.

Description

The value of a character constant is the string of characters between the delimiters. The value does not include the delimiters, but does include all blanks or tabs within the delimiters.

If a character constant is delimited by apostrophes, use two consecutive apostrophes (`''`) to place an apostrophe character in the character constant.

Similarly, if a character constant is delimited by quotation marks, use two consecutive quotation marks ("") to place a quotation mark character in the character constant.

The length of the character constant is the number of characters between the delimiters, but two consecutive delimiters are counted as one character.

The length of a character constant must be in the range of 0 to 7188. Each character occupies one byte of memory.

If a character constant appears in a numeric context (such as an expression on the right side of an arithmetic assignment statement), it is considered a Hollerith constant.

A zero-length character constant is represented by two consecutive apostrophes or quotation marks.

Examples

Valid Character Constants

```
"WHAT KIND TYPE? "

'TODAY''S DATE IS: '
```

```
"The average is: "

''
```

Invalid Character Constants

`'HEADINGS`	No trailing apostrophe.
`'Map Number:"`	Beginning delimiter does not match ending delimiter.

Declaration Statements for Character Types

C Strings in Character Constants

String values in the C language are terminated with null characters (CHAR(0)) and can contain nonprintable characters (such as backspace).

Nonprintable characters are specified by escape sequences. An escape sequence is denoted by using the backslash (\) as an escape character, followed by a single character indicating the nonprintable character desired.

This type of string is specified by using a standard string constant followed by the character C. The standard string constant is then interpreted as a C-language constant. Backslashes are treated as escapes, and a null character is automatically appended to the end of the string (even if the string already ends in a null character).

The following table shows the escape sequences that are allowed in character constants:

C-Style Escape Sequences

Escape Sequence	Represents
\a or \A	A bell
\b or \B	A backspace
\f or \F	A formfeed
\n or \N	A new line
\r or \R	A carriage return
\t or \T	A horizontal tab
\v or \V	A vertical tab
\x*hh* or \X*hh*	A hexadecimal bit pattern
ooo	An octal bit pattern
\0	A null character
\\	A backslash

If a string contains an escape sequence that isn't in this table, the backslash is ignored.

A C string must also be a valid Fortran string. If the string is delimited by apostrophes, apostrophes in the string itself must be represented by two consecutive apostrophes (`''`).

For example, the escape sequence `\'string` causes a compiler error because Fortran interprets the apostrophe as the end of the string. The correct form is `\''string`.

If the string is delimited by quotation marks, quotation marks in the string itself must be represented by two consecutive quotation marks ("").

The sequences \ooo and \x*hh* allow any ASCII character to be given as a one- to three-digit octal or a one- to two-digit hexadecimal character code. Each octal digit must be in the range 0 to 7, and each hexadecimal digit must be in the range 0 to F. For example, the C strings `'\010'C` and `'\x08'C` both represent a backspace character followed by a null character.

The C string `'\\abcd'C` is equivalent to the string `'\abcd'` with a null character appended. The string `''C` represents the ASCII null character.

Character Substrings

A *character substring* is a contiguous segment of a character string. It takes one of the following forms:

v ([*e1*]:[*e2*])

a (*s* [, *s*] . . .) ([*e1*]:[*e2*])

v	Is a character scalar constant, or the name of a character scalar variable or character structure component.
e1	Is a scalar integer (or other numeric) expression specifying the leftmost character position of the substring; the *starting* point.
e2	Is a scalar integer (or other numeric) expression specifying the rightmost character position of the substring; the *ending* point.
a	Is the name of a character array.
s	Is a subscript expression.

Both *e1* and *e2* must be within the range 1,2, ..., *len*, where *len* is the length of the parent character string. If *e1* exceeds *e2*, the substring has length zero.

Description

Character positions within the parent character string are numbered from left to right, beginning at 1.

If the value of the numeric expression *e1* or *e2* is not of type integer, it is converted to integer before use (any fractional parts are truncated).

If *e1* is omitted, the default is 1. If *e2* is omitted, the default is *len*. For example, NAMES(1,3)(:7) specifies the substring starting with the first character position and ending with the seventh character position of the character array element NAMES(1,3).

Examples

Consider the following example:

```
CHARACTER*8 C, LABEL
LABEL = 'XVERSUSY'
C = LABEL(2:7)
```

LABEL(2:7) specifies the substring starting with the second character position and ending with the seventh character position of the character variable assigned to LABEL, so C has the value `'VERSUS'`.

Consider the following example:

```
TYPE ORGANIZATION
  INTEGER ID
  CHARACTER*35 NAME
END TYPE ORGANIZATION
TYPE(ORGANIZATION) DIRECTOR
CHARACTER*25 BRANCH, STATE(50)
```

The following are valid substrings based on this example:

```
BRANCH(3:15)           ! parent string is a scalar variable
STATE(20) (1:3)        ! parent string is an array element
DIRECTOR%NAME(:)       ! parent string is a structure component
```

Consider the following example:

```
CHARACTER(*), PARAMETER :: MY_BRANCH = "CHAPTER 204"
CHARACTER(3) BRANCH_CHAP
BRANCH_CHAP = MY_BRANCH(9:11)   ! parent string is a character constant
```

BRANCH_CHAP is a character string of length 3 that has the value `'204'`.

Derived Data Types

You can create derived data types from intrinsic data types or previously defined derived types.

A derived type is resolved into "ultimate" components that are either of intrinsic type or are pointers.

The set of values for a specific derived type consists of all possible sequences of component values permitted by the definition of that derived type. Structure constructors are used to specify values of derived types.

Nonintrinsic assignment for derived-type entities must be defined by a subroutine with an ASSIGNMENT interface. Any operation on derived-type entities must be defined by a function with an OPERATOR interface. Arguments and function values can be of any intrinsic or derived type.

A derived type can be parameterized by type parameters. Each type parameter is defined to be either a kind or a length type parameter, and can have a default value.

Derived-Type Definition Overview

A derived-type definition specifies the name of a user-defined type and the types of its components. For more information on the syntax of a derived-type definition, see TYPE. For more information on derived-type definitions for polymorphic objects, see CLASS.

Default Initialization

Default initialization occurs if initialization appears in a derived-type component definition.

The specified initialization of the component will apply even if the definition is PRIVATE.

Default initialization applies to dummy arguments with INTENT(OUT). It does not imply the derived-type component has the SAVE attribute.

Explicit initialization in a type declaration statement overrides default initialization.

To specify default initialization of an array component, use a constant expression that includes one of the following:

- An array constructor
- A single scalar that becomes the value of each array element

Pointers can have an association status of associated, disassociated, or undefined. If no default initialization status is specified, the status of the pointer is undefined. To specify disassociated status for a pointer component, use =>NULL( ). To default initialize a pointer component as associated with the target T, use => T.

Examples

You do not have to specify initialization for each component of a derived type. For example:

```
TYPE REPORT
  CHARACTER (LEN=20) REPORT_NAME
  INTEGER DAY
  CHARACTER (LEN=3) MONTH
  INTEGER :: YEAR = 1995        ! Only component with default
END TYPE REPORT                 !      initialization
```

Consider the following:

```
TYPE (REPORT), PARAMETER :: NOV_REPORT = REPORT ("Sales", 15, "NOV", 1996)
```

In this case, the explicit initialization in the type declaration statement overrides the YEAR component of NOV_REPORT.

The default initial value of a component can also be overridden by default initialization specified in the type definition. For example:

```
TYPE MGR_REPORT
  TYPE (REPORT) :: STATUS = NOV_REPORT
  INTEGER NUM
END TYPE MGR_REPORT
TYPE (MGR_REPORT) STARTUP
```

In this case, the STATUS component of STARTUP gets its initial value from NOV_REPORT, overriding the initialization for the YEAR component.

Initialization expressions

Procedure Pointers as Derived-Type Components

A component of derived type can be a procedure pointer. A procedure pointer component definition takes the following form:

`PROCEDURE` ([*proc-interface*]), *proc-attr* [, *proc-attr*]... :: *proc-decl-list*

proc-interface — (Optional) Is the name of an interface or a type specifier.

proc-attr — Is one of the following attributes:

- PUBLIC
- PRIVATE
- POINTER (required)
- NOPASS or PASS [(*arg-name*)]

  where *arg-name* is the name of a dummy argument.

  PASS and NOPASS refer to passed-object dummy arguments. They are mutually exclusive. You can only specify one or the other in a *proc-attr* list, not both.

If you specify NOPASS, procedures will not have have passed-object dummy arguments. NOPASS is required if the interface is implicit.

The PASS attribute can be used to confirm the default (as the first argument), The NOPASS attribute prevents passing the object as an argument.

Each *proc-attr* can only appear once in a given component definition.

proc-decl-list Is one or more of the following:

procedure-name [=> *null-init*]

where *null-init* is a reference to intrinsic function NULL with no arguments.

If => null-init appears, the procedure must have the POINTER attribute.

Examples

The following example defines a type that represents a list of procedures with the same interface, which can be called at some future time:

```
TYPE PROCEDURE_LIST
  PROCEDURE (PROC_INTERFACE), POINTER :: PROC
  TYPE (PROCEDURE_LIST), POINTER :: NEXT => NULL()
END TYPE PROCEDURE_LIST
ABSTRACT INTERFACE
  SUBROUTINE PROC_INTERFACE
  ...
  END SUBROUTINE PROC_INTERFACE
END INTERFACE
```

A procedure pointer can be pointer-assigned to a procedure pointer variable, invoked directly, or passed as an actual argument. For example:

```
TYPE (PROCEDURE_LIST) :: a, b(6)
PROCEDURE (PROC_INTERFACE), POINTER :: R
...
R => a%PROC
CALL SUBROUTINE_NEXT(a%PROC)
CALL b(i)%PROC
```

Type-Bound Procedures

In a derived-type definition, you can optionally specify a type-bound-procedure-part, which consists of a CONTAINS statement, optionally followed by a PRIVATE statement, and one or more procedure binding statements. Specific, GENERIC, and FINAL procedure bindings are defined below.

A *type-bound-procedure-part* in a derived-type definition declares one or more type-bound procedures. It takes the following form:

```
CONTAINS
[PRIVATE]
proc-binding-stmt
[ proc-binding-stmt]...
```

proc-binding-stmt Is one of the following:

- *specific-binding*
- *generic-binding*
- *final-binding*

The default accessibility of type-bound procedures is public even if the components are private. You can change this by including the PRIVATE statement following the CONTAINS statement.

specific-binding
A specific type-bound procedure binds a procedure to a type or it specifies a deferred binding to an abstract type. It takes the following form:

PROCEDURE (*interface-name*), *binding-attr-list* :: *binding-name* [, *binding-name*]...

PROCEDURE [[, *binding-attr-list*] ::] *binding-name* [=> *procedure-name*] [, [*binding-name* [=> *procedure-name*]]…]

interface-name
(Optional) Is the interface for the procedure. It must be the name of an abstract interface or a procedure that has an explicit interface. *interface-name* can only be specified if the binding has the DEFERRED attribute.

binding-attr-list
(Optional) Is one or more of the following. The same attribute can only appear once for the same binding:

- PASS [(*arg-name*)]

  Defines the "passed-object dummy argument" of the procedure. If *arg-name* is specified, the interface of the binding must have a dummy argument named *arg-name*.
- NOPASS

  Indicates that the procedure has no passed-object dummy argument. Use this keyword if the procedure pointer component has an implicit interface or has no arguments. PASS and NOPASS can not both be specified for the same binding.
- *access-spec*

  Is the PUBLIC or PRIVATE attribute.
- NON_OVERRIDABLE

  Determines whether a binding can be overridden in an extended type. You must not specify NON_OVERRIDABLE for a binding with the DEFERRED attribute.
- DEFERRED

  Indicates that the procedure is deferred. Deferred bindings must only be specified for derived-type definitions with the ABSTRACT attribute. A procedure with the DEFERRED binding attribute must specify an *interface-name*. An overriding binding can have the DEFERRED attribute only if the binding it overrides is deferred. The NON_OVERRIDABLE and DEFERRED binding attributes must not both be specified for the same procedure.

binding-name
Is the name of the type-bound procedure. It is referred to in the same way as a component of a type.

procedure-name
(Optional) Is the name of the actual procedure which implements *binding-name*. It is the name of an accessible module procedure or an external procedure that has an explicit interface. It defines the interface for the procedure, and the procedure to be executed when the procedure is referenced.

If neither =>procedure-name nor interface-name appears, the *procedure-name* is the same as the binding-name. If =>procedure-name appears, you must specify the double-colon separator and you must not specify an interface-name.

In general, the invoking variable, the passed-object dummy argument, is passed as an additional argument. By default, this is the first dummy argument of the actual procedure. So, the first argument in the argument list becomes the second argument, etc.

A passed-object dummy argument can be changed by declaring the type-bound procedure with the PASS(arg-name) attribute. In this case, the variable is passed as the named argument. The PASS attribute can also be used to confirm the default as the first argument. The NOPASS attribute prevents passing the object as an argument.

Consider the following:

```
TYPE MY_TYPE
...   ! Component declarations
CONTAINS
  PROCEDURE :: PROC1 => MY_PROC
  PROCEDURE :: PROC2, PROC3 => MY_PROC3
  PROCEDURE :: PROC4 => MY_PROC4, PROC5 => MY_PROC5
END TYPE MY_TYPE
```

This binds MY_PROC with the PROC1.

If B is a scalar variable of type MY_TYPE, an example of a type-bound call is:

```
CALL B%PROC1(C, D)
```

When PASS is in effect, the call passes B to the first argument of the procedure, C to the second argument, and D to the third argument.

generic-binding
A generic type-bound procedure defines a generic interface that is bound to the type. For more information, see the GENERIC statement.

final-binding
An extensible derived type can have one or more "final subroutines" associated with it. A final subroutine can be executed to perform clean-up operations after a data entity of that type is finalized (ceases to exist). For more information, see the FINAL statement.

TYPE

Passed-Object Dummy Arguments

PROCEDURE statement

Type Extension

Type extension lets you create new derived types by extending pre-existing derived types.

Any derived type can be extended using the EXTENDS keyword, except for types with the SEQUENCE or BIND(C) attributes. SEQUENCE types and BIND(C) types (as well as intrinsic types) are non-extensible.

The extended type either inherits or overrides each type-bound procedure of the parent type. An overriding procedure must be compatible with the parent procedure; in particular, each dummy argument must have the same type except for the passed-object dummy argument which must have the new type. A type-bound procedure that is declared to be NON_OVERRIDABLE cannot be overridden during type extension.

The extended type inherits all the components and parameters of the parent type and they are known by the same name. The extended type can also specify additional components.

For example, consider the following derived-type definition:

```
TYPE PERSON_INFO
  INTEGER :: AGE
  CHARACTER (LEN = 60) :: NAME
END TYPE PERSON_INFO
```

Derived type PERSON_INFO (the parent type) can be extended to create a new type as follows:

```
TYPE, EXTENDS (PERSON_INFO) :: EMPLOYEE_DATA
  INTEGER :: ID
  REAL :: SALARY
END TYPE EMPLOYEE_DATA
```

Extended type EMPLOYEE_DATA inherits all the components in type PERSON_INFO, as well as additional components ID and SALARY.

TYPE

Passed-Object Dummy Arguments

Parameterized Derived-Type Declarations

A derived type is parameterized if the derived TYPE statement has type parameter names or it inherits any type parameters.

The type parameters must be listed in the type definition. You must specify a type and you must specify whether they are KIND or LEN parameters. A type parameter definition takes the following form:

`INTEGER` [*kind-selector*], *type-param-attr-spec* :: *type-param-decl-list*

kind-selector	(Optional) Is one of the kind type parameter numbers allowed for integer data types. For more information, see Integer Data Types. If you do not specify *kind-selector*, default integer kind is assumed.
type-param-attr-spec	Is KIND or LEN.
type-param-decl-list	Is one or more of the following separated by commas: *type-param-name* [= *init-spec*]
type-param-name	Is the name of the type parameter. Each *type-param-name* must match one of the *type-param-name* parameters listed in the derived TYPE statement.
init-spec	(Optional) Must be a scalar integer constant expression.

If *init-spec* is specified, the type parameter has a default value that is specified by the expression *init-spec*. If necessary, the value of *init-spec* is converted to an integer value of the same kind as the type parameter in accordance with the rules of intrinsic assignment.

Explicit values for the type parameters are normally specified when an object of the parameter type is declared.

Within the type definition, kind type parameters may be used in constant expressions and specification expressions. Length type parameters may be used in specification expressions but not in constant expressions. The type parameters need not be used anywhere in the derived type.

Kind type parameters also participate in generic resolution Unambiguous Generic Procedure References. A single generic can include two specific procedures that have interfaces distinguished only by the value of a kind type parameter of a dummy argument.

An explicit interface is required if a parameterized derived type is used as a dummy argument. In a SELECT TYPE construct, the kind type parameter values of a type guard statement must be the same as those of the dynamic type of the selector. A BIND(C) type and a SEQUENCE type must not have type parameters.

Advantages to Using This Feature

Adding type parameters to a derived type allows you to declare objects of similar types that differ depending on the kind and length parameters used in the object declaration. For example, the type definition `matrix` below has two type parameters, a kind parameter `k` and a length parameter `b`.

```
TYPE matrix ( k, b )
  INTEGER,     KIND :: k = 4
  INTEGER (8), LEN  :: b
  REAL (k)          :: element (b,b)
END TYPE matrix
```

The user can declare a matrix named `square` of 10 by 10 elements of REAL(8) with the following declaration:

```
TYPE (matrix (8, 10)) :: square
```

The user can declare another matrix named `big_square` of 100 by 100 elements of REAL(4) with the following declaration:

```
TYPE (matrix (10)) :: square    ! k defaults to 4
```

Parameterized TYPE Statements
SELECT TYPE
SEQUENCE

Parameterized TYPE Statements

A derived *type-spec* (see Type Declarations) in a parameterized type declaration has the general form:

type-name [(*type-param-spec-list*)]

type-name	Is an accessible derived type.
type-param-spec-list	Is one or more of the following separate by commas: [*keyword* =] *type-param-value*
keyword	Is the name of a type parameter for the type *type-name*.
type-param-value	Is a scalar integer expression or an asterisk "*" or a colon ":".

A *type-param-spec-list* must appear only if the type is parameterized. There must be at most one *type-param-spec* corresponding to each parameter of the type. If a type parameter does not have a default value, there must be a *type-param-spec* corresponding to that type parameter.

The following topics in this section include cumulative examples demonstrating various kinds of parameterized TYPE statements.

Examples

Consider the following:

```
TYPE matrix (k, d1, d2)
  INTEGER, KIND :: k = kind (0.0)                  ! k has a default value
  INTEGER (selected_int_kind (12)), LEN :: d1, d2  ! Non-default kind for d1
  REAL (k) :: element (d1 ,d2)
END TYPE
! dim is an integer variable
TYPE(matrix(k = KIND(0d0), d1=200+5, d2=dim)) :: my_matrix1
! k has a default value and so the type-param-spec can be omitted
TYPE(matrix(d1=2*dim, d2=dim)) :: my_matrix2
TYPE(matrix(KIND(0d0), :, :)), pointer :: my_deferred_matrix
TYPE(matrix(KIND(0d0), *, *)) :: my_assumed_matrix
```

Each keyword must be the name of one of the parameters of the type. Similar to keyword arguments in procedure calls, "keyword=" can be omitted only if "keyword=" has been omitted for each preceding type parameter. If a keyword appears, the value corresponds to the type parameter named by the keyword. If keywords do not appear, the value corresponds to type parameters in type parameter order. If necessary, the value is converted according to the rules of intrinsic assignment to a value of the same kind as the type parameter.

Parameterized Derived-Type Declarations

Structure Constructors for Parameterized Derived Types

A *type-param-spec-list* must be given when constructing a parameterized derived type. See Parameterized TYPE Statements.

The syntax takes the following form:

derived-type-spec ([*comp-spec-list*])

derived-type-spec	Is a derived *type-spec*. See Type Declarations for details on derived type specifications.
comp-spec-list	Is a list of one or more component specifications.

Example

```
Matrix (kind (0.0),1,3) :: my_matrix
my_matrix =  matrix (kind (0.0),1,3) ([1.0,2.0,3.0])
```

See Also

Parameterized Derived-Type Declarations
Parameterized TYPE Statements
Structure Constructors

Type Parameter Order for Parameterized Derived Types

The type parameter order of a non-extended type is the order of the type parameter list in the derived type definition. The type parameter order of an extended type consists of the order of its parent type followed by the order of the type parameter list in the derived type definition.

A type parameter declared in an extended type must not have the same name as any accessible component or type parameter of its parent type.

Examples

Consider the following:

```
Type :: t1 (k1,k2)
  Integer, kind :: k1,k2
  Real(k1) ::  a(k2)
End type

Type, extends (t1) :: t2(k3)
  Integer, kind :: k3
  Logical(k3) flag
End type
```

The type parameter order for type `t1` is `k1`, then `k2`.

The type parameter order for type `t2` is `k1`, then `k2`, then `k3`.

See Also

Parameterized Derived-Type Declarations
Parameterized TYPE Statements

Deferred-Length Type Parameters for Parameterized Derived Types

Similar to deferred character lengths and deferred array bounds, the length type parameters of a derived type can be deferred. A deferred-length type parameter is specified when *type-param-value* in the *type-param-spec* is a colon (":").

A derived type object with a deferred-length type parameter must have an ALLOCATABLE or POINTER attribute. The value of a deferred type parameter is deferred until allocation or association.

When the dummy argument is allocatable or a pointer, the actual argument must have deferred the same type parameters as the dummy argument.

```
TYPE(matrix(k=KIND(0.0), d1= :, d2= :)), pointer :: my_mtrx_ptr, my_mtrx_alloc
TYPE(matrix(KIND(0.0), 100, 200)), target :: my_mtrx_tgt
TYPE(matrix(KIND(0.0), 1, 2)) :: my_mtrx_src
```

```
my_mtrx_ptr => my_mtrx_tgt   ! Gets values from target
! my_mtrx_ptr has d1= 100 and d2 = 200.

ALLOCATE(matrix(KIND(0.0), 10, 20) :: my_mtrx_alloc)  ! Gets values from allocation
! my_mtrx_alloc has d1=10 and d2=20
DEALLOCATE(my_mtrx_alloc)

ALLOCATE(my_mtrx_alloc, source=my_mtrx_src)  ! Gets values from allocation
! my_mtrx_alloc has d1=1 and d2=2
```

All *non-deferred* type parameter values of the declared type of the pointer object that correspond to non-deferred type parameters of the pointer target must agree. If a pointer object has non-deferred type parameters that correspond to deferred type parameters of a pointer target, the pointer target must not have undefined association status.

Deferred type parameters of functions, including function procedure pointers, have no values. Instead, they indicate that those type parameters of the function result will be determined by execution of the function, if it returns an allocated allocatable result or an associated pointer result.

If an ALLOCATE statement specifies a derived type object with deferred type parameters, it must either have the derived-type specification or a *source-expr* (a scalar expression). The kind type parameter values and the non-deferred length type parameter values in the derived-type specification or *source-expr* must be the same as the corresponding values of the derived type object.

```
TYPE(matrix(k=KIND(0.0), d1= 100, d2= :)), pointer :: my_mtrx_alloc
TYPE(matrix(KIND(0.0), 1, 2)) :: my_mtrx_src

ALLOCATE(my_mtrx_alloc, source=my_mtrx_src)  ! Illegal - d1 is not deferred
! my_mtrx_src must have the same value for d1
```

POINTER - Fortran

Assumed-Length Type Parameters for Parameterized Derived Types

The length type parameter is assumed when an asterisk is used as a *type-param-value* in a *type-param-spec*. An asterisk may be used only in the declaration of a dummy argument, in the associate name in a SELECT TYPE statement, or in the allocation of a dummy argument. The value is taken from that of the actual argument.

```
Type(matrix(KIND(0d0), 10, :)), pointer :: y(:)
Call print_matrix(y)
...
Subroutine print_matrix(x)

  ! d1 here is assumed and its value '10' is obtained from the actual argument
  Type(matrix(k= KIND(0d0), d1=*, d2=:), pointer :: x(:)
  ALLOCATE(matrix(KIND(0.0), *, 10) :: x(10))
  ...
End Subroutine
```

All length type parameters of the dummy argument must be assumed for a final subroutine. All length type parameters of the first dummy argument to a user-defined I/O subroutine must be assumed. All of the length type parameters of a passed-object dummy argument must be assumed. In a SELECT TYPE construct, each length type parameter in a *type-guard-stmt* must be assumed.

Array Constructors

If *type-spec* in an array constructor specifies a parameterized derived type, all *ac-value* expressions in the array constructor must be of that derived type and must have the same kind type parameter values as specified by *type-spec*. Also, *type-spec* specifies the declared type and type parameters of the array constructor.

Each *ac-value* expression in the array constructor must be compatible with intrinsic assignment to a variable of this type and type parameter. Each value is converted to the type parameters of the array constructor in accordance with the rules of intrinsic assignment.

If *type-spec* is omitted, each *ac-value* expression in the array constructor must have the same length type parameters; in which case, the declared type and type parameters of the array constructor are those of the *ac-value* expressions.

Type Parameter Inquiry

The value of a derived-type parameter can be accessed from outside the type definition, using the same notation as component access.

```
print *,'No: of Rows =',my_matrix%d1
print *,'No: of Columns =',my_matrix%d2
```

Unlike components, a type parameter inquiry cannot be used on the left-hand side of an assignment, and type parameters are effectively always public. The value of a deferred type parameter of an unallocated allocatable, or of a pointer that is not associated with a target, is undefined and must not be inquired about. The length type parameters of an optional dummy argument that is not present must not be the subject of an inquiry.

The type parameters of intrinsic types can also be inquired using this syntax. The result is always scalar, even if the object is an array.

```
REAL(selected_real_kind(10,20)) :: z(100)
..
PRINT *,z%kind ! A single value is printed
```

This is same as calling KIND(z). However, the type parameter inquiry can be used even when the intrinsic function is not available.

```
Subroutine write_centered(ch, len)
  Character(*), intent(inout) :: ch
  Integer, intent(in) :: len
  Integer :: i
  Do i=1, (len - ch%len)/2
  ...
! The inquiry ch%len cannot be replaced with len(ch) since len is the
! name of a dummy argument
```

SELECT TYPE

Structure Components

A reference to a component of a derived-type structure takes the following form:

parent [(*s-list*)] [*image-selector*] [%*component* [(*s-list*)] [*image-selector*]] ... %*component* [(*s-list*)] [*image-selector*]

parent	Is the name of a scalar or array of derived type. The percent sign (%) is called a component selector.
component	Is the name of a component of the immediately preceding parent or component.
s-list	Is a list of one or more subscripts. If the list contains subscript triplets or vector subscripts, the reference is to an array section. Each subscript must be a scalar integer (or other numeric) expression with a value that is within the bounds of its dimension. The number of subscripts in any *s-list* must equal the rank of the immediately preceding parent or component.
image-selector	Is an image selector if the parent or component is a coarray. For more information, see Image Selectors.

Description

Each parent or component (except the rightmost) must be of derived type.

The parent or one of the components can have nonzero rank (be an array). Any component to the right of a parent or component of nonzero rank must not have the POINTER attribute.

The rank of the structure component is the rank of the part (parent or component) with nonzero rank (if any); otherwise, the rank is zero. The type and type parameters (if any) of a structure component are those of the rightmost part name.

The structure component must not be referenced or defined before the declaration of the parent object.

If the parent object has the INTENT, TARGET, or PARAMETER attribute, the structure component also has the attribute.

If the rightmost component is of type C_PTR or C_FUNPTR from the intrinsic module ISO_C_BINDING, each parent or component must not have an *image-selector*.

Examples

The following example shows a derived-type definition with two components:

```
TYPE EMPLOYEE
  INTEGER ID
  CHARACTER(LEN=40) NAME
END TYPE EMPLOYEE
```

The following shows how to declare CONTRACT to be of type EMPLOYEE:

```
TYPE(EMPLOYEE) :: CONTRACT
```

Note that both examples started with the keyword TYPE. The first (initial) statement of a derived-type definition is called a derived-type statement, while the statement that declares a derived-type object is called a TYPE statement.

The following example shows how to reference component ID of parent structure CONTRACT:

```
CONTRACT%ID
```

The following example shows a derived type with a component that is a previously defined type:

```
TYPE DOT
  REAL X, Y
END TYPE DOT
....
```

```
TYPE SCREEN
  TYPE(DOT) C, D
END TYPE SCREEN
```

The following declares a variable of type SCREEN:

```
TYPE(SCREEN) M
```

Variable M has components M%C and M%D (both of type DOT); M%C has components M%C%X and M%C %Y of type REAL.

The following example shows a derived type with a component that is an array:

```
TYPE CAR_INFO
  INTEGER YEAR
  CHARACTER(LEN=15), DIMENSION(10) :: MAKER
  CHARACTER(LEN=10) MODEL, BODY_TYPE*8
  REAL PRICE
END TYPE
...
TYPE(CAR_INFO) MY_CAR
```

Note that MODEL has a character length of 10, but BODY_TYPE has a character length of 8. You can assign a value to a component of a structure; for example:

```
MY_CAR%YEAR = 1985
```

The following shows an array structure component:

```
MY_CAR%MAKER
```

In the preceding example, if a subscript list (or substring) was appended to MAKER, the reference would not be to an array structure component, but to an array element or section.

Consider the following:

```
MY_CAR%MAKER(2) (4:10)
```

In this case, the component is substring 4 to 10 of the second element of array MAKER.

Consider the following:

```
TYPE CHARGE
   INTEGER PARTS(40)
   REAL LABOR
   REAL MILEAGE
 END TYPE CHARGE

 TYPE(CHARGE) MONTH
 TYPE(CHARGE) YEAR(12)
```

Some valid array references for this type follow:

```
MONTH%PARTS(I)           ! An array element
MONTH%PARTS(I:K)         ! An array section
YEAR(I)%PARTS            ! An array structure component (a whole array)
YEAR(J)%PARTS(I)         ! An array element
YEAR(J)%PARTS(I:K)       ! An array section
YEAR(J:K)%PARTS(I)       ! An array section
YEAR%PARTS(I)            ! An array section
```

The following example shows a derived type with a pointer component that is of the type being defined:

```
TYPE NUMBER
  INTEGER NUM

  TYPE(NUMBER), POINTER :: START_NUM => NULL( )
  TYPE(NUMBER), POINTER :: NEXT_NUM => NULL( )

END TYPE
```

A type such as this can be used to construct linked lists of objects of type NUMBER. Note that the pointers are given the default initialization status of disassociated.

The following example shows a private type:

```
TYPE, PRIVATE :: SYMBOL
  LOGICAL TEST
  CHARACTER(LEN=50) EXPLANATION
END TYPE SYMBOL
```

This type is private to the module. The module can be used by another scoping unit, but type SYMBOL is not available.

The following example shows how to dereference an array of structures with a coarray structure component that is a real array:

```
TYPE REAL_ARRAY
  REAL,ALLOCATABLE    :: RA(:)
END TYPE

TYPE CO_ARRAY
  TYPE(REAL_ARRAY)    :: CA[*]
END TYPE

TYPE STRUCT
  TYPE(CO_ARRAY)      :: COMP
END TYPE

TYPE(STRUCT)          :: ARRAY(10, 10)

ALLOCATE(ARRAY(5,10)%COMP%CA%RA(10))
ARRAY(5,10)%COMP%CA[5]%RA(:) = 0
```

Structure Constructors

A structure constructor lets you specify scalar values of a derived type. It takes the following form:

d-name (*comp-spec*)

d-name	Is the name of the derived type. It cannot be an abstract type.
comp-spec	Is a component specification. Only one *comp-spec* can be specified for a component. However, you can specify more than one *comp-spec* in a constructor. A component specification takes the following form: [*keyword*=] *comp-data-source*

keyword	Is the name of a component of the derived type *d-name*.
comp-data-source	Is one of the following: • *expr* • *data-target* • *proc-target*
expr	Is an expression specifying component values. The values must agree in number and order with the components of the derived type. If necessary, values are converted (according to the rules of assignment), to agree with their corresponding components in type and kind parameters.
data-target	Is a data pointer component. It must have the same rank as its corresponding component.
proc-target	Is a procedure pointer component.

Description

A structure constructor must not appear before its derived type is defined.

If *keyword*= appears, any *expr* is assigned to the component named by the keyword. If *keyword*= is omitted, each *comp-data-source* is assigned to the corresponding component in component order. The *keyword*= can be omitted from a *comp-spec* only if the *keyword*= has been omitted from each preceding *comp-spec* in the constructor, if any.

If a component of the derived type is an array, the shape in the expression list must conform to the shape of the component array.

If a component of the derived type is a pointer, the value in the expression list must evaluate to an object that would be a valid target in a pointer assignment statement. (A constant is not a valid target in a pointer assignment statement.)

If all the values in a structure constructor are constant expressions, the constructor is a derived-type constant expression.

The type name and all components of the type for which a *comp-spec* appears must be accessible in the scoping unit containing the structure constructor.

For a pointer component, the corresponding *comp-data-source* must be an allowable *data-target* or *proc-target* for such a pointer in a pointer assignment statement. If the *comp-data-source* is a pointer, the association of the component is that of the pointer; otherwise, the component is pointer-associated with the *comp-data-source*.

If a component with default initialization has no corresponding *comp-data-source*, then the default initialization is applied to that component.

If a component of a derived type is allocatable, the corresponding constructor expression must either be a reference to the intrinsic function NULL with no arguments or an allocatable entity of the same rank, or it must evaluate to an entity of the same rank.

If the expression is a reference to the intrinsic function NULL, the corresponding component of the constructor has a status of unallocated.

If the expression is an allocatable entity, the corresponding component of the constructor has the same allocation status as that allocatable entity. If the entity is allocated, the constructor component has the same dynamic type, bounds, and value. If a length parameter of the component is deferred, its value is the same as the corresponding parameter of the expression. Otherwise the corresponding component of the constructor has an allocation status of allocated and has the same bounds and value as the expression.

Examples

Consider the following derived-type definition:

```
TYPE EMPLOYEE
  INTEGER ID
  CHARACTER(LEN=40) NAME
END TYPE EMPLOYEE
```

This can be used to produce the following structure constructor:

```
EMPLOYEE(3472, "John Doe")
```

The following example shows a type with a component of derived type:

```
TYPE ITEM
  REAL COST
  CHARACTER(LEN=30) SUPPLIER
  CHARACTER(LEN=20) ITEM_NAME
END TYPE ITEM

TYPE PRODUCE
  REAL MARKUP
  TYPE(ITEM) FRUIT
END TYPE PRODUCE
```

In this case, you must use an embedded structure constructor to specify the values of that component; for example:

```
PRODUCE(.70, ITEM (.25, "Daniels", "apple"))
```

Binary, Octal, Hexadecimal, and Hollerith Constants

Binary, octal, hexadecimal, and Hollerith constants are nondecimal constants. They have no intrinsic data type, but assume a numeric data type depending on their use.

Standard Fortran allows unsigned binary, octal, and hexadecimal constants to be used in DATA statements; the constant must correspond to an integer scalar variable. These constants may also appear as arguments to certain standard intrinsic functions as indicated in their individual descriptions.

Each digit of a binary, octal, or hexadecimal literal constant represents a sequence of bits, according to its numerical interpretation (see Model for Bit Data) with *s* in the model equal to the following:

- one for binary constants
- three for octal constants
- four for hexadecimal constants

A binary, octal, or hexadecimal literal constant represents a sequence of bits that consists of the concatenation of the sequences of bits represented by its digits, in the order that the digits are specified. The positions of bits in the sequence are numbered from right to left, with the position of the rightmost bit being zero.

The length of a sequence of bits is the number of bits in the sequence. The position of the leftmost nonzero bit is interpreted to be at least *m* - 1, where *m* is the maximum value that could result from invoking the intrinsic function STORAGE SIZE with an argument that is a real or an integer scalar of any kind supported by the processor.

In Intel® Fortran, binary, octal, hexadecimal, and Hollerith constants can appear wherever numeric constants are allowed.

Determining the Data Type of Nondecimal Constants
Bit Sequence Comparisons

Binary Constants

A *binary constant* is an alternative way to represent a numeric constant. A binary constant takes one of the following forms:

B'*d*[*d*...]'

B"*d*[*d*...]"

d	Is a binary (base 2) digit (0 or 1).

You can specify up to 128 binary digits in a binary constant.

Examples

Valid Binary Constants

```
B'0101110'

B"1"
```

Invalid Binary Constants

`B'0112'`	The character 2 is invalid.
`B10011'`	No apostrophe after the B.
`"1000001"`	No B before the first quotation mark.

See Also

Alternative Syntax for Binary, Octal, and Hexadecimal Constants

Octal Constants

An *octal constant* is an alternative way to represent numeric constants. An octal constant takes one of the following forms:

O'*d*[*d*...]'

O"*d*[*d*...]"

d	Is an octal (base 8) digit (0 through 7).

You can specify up to 128 bits (43 octal digits) in octal constants.

Examples

Valid Octal Constants

```
O'07737'

O"1"
```

Invalid Octal Constants

`O'7782'`	The character 8 is invalid.
`O7772'`	No apostrophe after the O.

"0737"	No O before the first quotation mark.

See Also

Alternative Syntax for Binary, Octal, and Hexadecimal Constants

Hexadecimal Constants

A *hexadecimal constant* is an alternative way to represent numeric constants. A hexadecimal constant takes one of the following forms:

Z'*d*[*d*...]'

Z"*d*[*d*...]"

d	Is a hexadecimal (base 16) digit (0 through 9, or an uppercase or lowercase letter in the range of A to F).

You can specify up to 128 bits (32 hexadecimal digits) in hexadecimal constants.

Examples

Valid Hexadecimal Constants

```
Z'AF9730'

Z"FFABC"

Z'84'
```

Invalid Hexadecimal Constants

Z'999.'	Decimal not allowed.
ZF9"	No quotation mark after the Z.

See Also

Alternative Syntax for Binary, Octal, and Hexadecimal Constants

Hollerith Constants

A *Hollerith constant* is a string of printable ASCII characters preceded by the letter H. Before the H, there must be an unsigned, nonzero default integer constant stating the number of characters in the string (including blanks and tabs).

Hollerith constants are strings of 1 to 2000 characters. They are stored as byte strings, one character per byte.

Examples

Valid Hollerith Constants

```
16HTODAY'S DATE IS:

1HB

4H ABC
```

Invalid Hollerith Constants

3HABCD	Wrong number of characters.

0H	Hollerith constants must contain at least one character.

Determining the Data Type of Nondecimal Constants

Binary, octal, hexadecimal, and Hollerith constants have no intrinsic data type. In most cases, the default integer data type is assumed.

However, these constants can assume a numeric data type depending on their use. When the constant is used with a binary operator (including the assignment operator), the data type of the constant is the data type of the other operand. For example:

Statement	Data Type of Constant	Length of Constant (in bytes)
INTEGER(2) ICOUNT		
INTEGER(4) JCOUNT		
INTEGER(4) N		
REAL(8) DOUBLE		
REAL(4) RAFFIA, RALPHA		
RAFFIA = B'1001100111111010011'	REAL(4)	4
RAFFIA = Z'99AF2'	REAL(4)	4
RALPHA = 4HABCD	REAL(4)	4
DOUBLE = B'1111111111100110011010'	REAL(8)	8
DOUBLE = Z'FFF99A'	REAL(8)	8
DOUBLE = 8HABCDEFGH	REAL(8)	8
JCOUNT = ICOUNT + B'011101110111'	INTEGER(2)	2
JCOUNT = ICOUNT + O'777'	INTEGER(2)	2
JCOUNT = ICOUNT + 2HXY	INTEGER(2)	2
IF (N .EQ. B'1010100') GO TO 10	INTEGER(4)	4
IF (N .EQ. O'123') GO TO 10	INTEGER(4)	4
IF (N. EQ. 1HZ) GO TO 10	INTEGER(4)	4

When a specific data type (generally integer) is required, that type is assumed for the constant. For example:

Statement	Data Type of Constant	Length of Constant (in bytes)
Y(IX) = Y(O'15') + 3.	INTEGER(4)	4
Y(IX) = Y(1HA) + 3.	INTEGER(4)	4

When a nondecimal constant is used as an actual argument, the following occurs:

- When binary, octal, and hexadecimal constants are specified as arguments to intrinsic functions, and the description of the function specifies the interpretation of such constants, that specified interpretation is used.
- For binary, octal, and hexadecimal constants in other actual argument contexts, if the value fits in a default integer, that integer kind is used. Otherwise, the smallest integer kind large enough to hold the value is used.
- For Hollerith constants, a numeric data type of sufficient size to hold the length of the constant is assumed.

For example:

Statement	Data Type of Constant	Length of Constant (in bytes)
`CALL APAC(Z'34BC2')`	INTEGER(4)	4
`CALL APAC(9HABCDEFGHI)`	REAL(16)	9

When a binary, octal, or hexadecimal constant is used in any other context, the default integer data type is assumed. In the following examples, default integer is INTEGER(4):

Statement	Data Type of Constant	Length of Constant (in bytes)
`IF (Z'AF77') 1,2,3`	INTEGER(4)	4
`IF (2HAB) 1,2,3`	INTEGER(4)	4
`I = O'7777' - Z'A39'`[1]	INTEGER(4)	4
`I = 1HC - 1HA`	INTEGER(4)	4
`J = .NOT. O'73777'`	INTEGER(4)	4
`J = .NOT. 1HB`	INTEGER(4)	4

[1] When two typeless constants are used in an operation, they both take default integer type.

When nondecimal constants are not the same length as the length implied by a data type, the following occurs:

- Binary, octal, and hexadecimal constants

  These constants can specify up to 16 bytes of data. When the length of the constant is less than the length implied by the data type, the leftmost digits have a value of zero.

  When the length of the constant is greater than the length implied by the data type, the constant is truncated on the left. An error results if any nonzero digits are truncated.

  The Data Type Storage Requirements table lists the number of bytes that each data type requires.
- Hollerith constants

  When the length of the constant is less than the length implied by the data type, blanks are appended to the constant on the right.

  When the length of the constant is greater than the length implied by the data type, the constant is truncated on the right. If any characters other than blank characters are truncated, a warning occurs.

  Each Hollerith character occupies one byte of memory.

Enumerations and Enumerators

An enumeration defines the name of a group of related values and the name of each value within the group. It takes the following form:

ENUM, BIND(C)

  ENUMERATOR [::] *c1* [= *expr*][, *c2* [= *expr*]]...

[ENUMERATOR [::] *c3* [= *expr*][, *c4* [= *expr*]]...]...

END ENUM

c1,*c2*,*c3*,*c4*	Is the name of the enumerator being defined.
expr	Is an optional scalar integer constant expression specifying the value for the enumerator.

If = appears in an enumerator, a double-colon separator must appear before the enumerator or list of enumerators.

The compiler ensures that the integer kind declared for the enumerator is compatible with the integer type used by the corresponding C enumeration. The processor uses the same representation for the types declared by all C enumeration specifiers that specify the same values in the same order.

An enumerator is treated as if it were explicitly declared with the PARAMETER attribute.

The order in which the enumerators appear in an enumerator definition is significant.

If you do not explicitly assign each enumerator a value by specifying an *expr*, the compiler assigns a value according to the following rules:

- If the enumerator is the first enumerator in the enumerator definition, the enumerator has the value 0.
- If the enumerator is not the first enumerator in the enumerator definition, its value is the result of adding one to the value of the immediately preceding enumerator in the enumerator definition.

You can define the enumerators in multiple ENUMERATOR statements or in one ENUMERATOR statement. The order in which the enumerators are declared in an enumeration definition is significant, but the number of ENUMERATOR statements is not.

Examples

The following example shows an enumeration definition:

```
ENUM, BIND(C)
  ENUMERATOR ORANGE
  ENUMERATOR :: RED = 5, BLUE = 7
  ENUMERATOR GREEN
END ENUM
```

The kind type parameter for this enumeration is processor dependent, but the processor must select a kind sufficient to represent the values of the enumerators.

The order of the enumerators is significant if the values are not assigned explicitly. In the above example, the value of ORANGE becomes defined as a named constant with the value zero and the value of GREEN becomes defined as a named constant with the value 8. Note that if RED was the enumerator preceding GREEN, the value of GREEN would be 6 rather than 8.

The following declaration may be considered to be equivalent to the above enumeration definition:

```
INTEGER(SELECTED_INT_KIND(4)), PARAMETER :: ORANGE = 0, RED = 5, BLUE = 7, GREEN = 8
```

An entity of the same kind type parameter value can be declared using the intrinsic function KIND with one of the enumerators as its argument, for example:

```
INTEGER(KIND(BLUE)) :: X
```

Variables

A variable is a data object whose value can be changed (defined or redefined) at any point in a program. A variable can be any of the following:

- A scalar

  A *scalar* is a single object that has a single value; it can be of any intrinsic or derived (user-defined) type.
- An array

An *array* is a collection of scalar elements of any intrinsic or derived type. All elements must have the same type and kind parameters.

- A subobject designator

  A subobject is part of an object. The following are subobjects:

  An array element

  An array section

  A structure component

  A character substring

  For example, B(3) is a subobject (array element) designator for array B. A subobject cannot be a variable if its parent object is a constant.
- A reference to a function that returns a data pointer

  A reference to a function that returns a data pointer is treated as a variable and is permitted in any variable-definition context .

The name of a variable is associated with a single storage location.

A *designator* is a name followed by zero or more component selectors, complex part selectors, array section selectors, array element selectors, image selectors, and substring selectors.

Variables are classified by data type, as constants are. The data type of a variable indicates the type of data it contains, including its precision, and implies its storage requirements. When data of any type is assigned to a variable, it is converted to the data type of the variable (if necessary).

A variable is *defined* when you give it a value. A variable can be defined before program execution by a DATA statement or a type declaration statement. During program execution, variables can be defined or redefined in assignment statements and input statements, or undefined (for example, if an I/O error occurs). When a variable is undefined, its value is unpredictable.

When a variable becomes undefined, all variables associated by storage association also become undefined.

An object with subobjects, such as an array, can only be defined when all of its subobjects are defined. Conversely, when at least one of its subobjects are undefined, the object itself, such as an array or derived type, is undefined.

This section also discusses the Data Types of Scalar Variables and Arrays.

See Also

Type Declarations

DATA statement
Data Type of a Numeric Expressions
Storage Association for details on storage association of variables

Data Types of Scalar Variables

The data type of a scalar variable can be explicitly declared in a type declaration statement. If no type is declared, the variable has an implicit data type based on predefined typing rules or definitions in an IMPLICIT statement.

An explicit declaration of data type takes precedence over any implicit type. Implicit type specified in an IMPLICIT statement takes precedence over predefined typing rules.

See Also

Specification of Data Type
Implicit Typing Rules

Specification of Data Type

Type declaration statements explicitly specify the data type of scalar variables. For example, the following statements associate VAR1 with a 16-byte complex storage location, and VAR2 with an 8-byte double-precision storage location:

```
COMPLEX(8) VAR1
REAL(8) VAR2
```

NOTE
If no kind parameter is specified for a data type, the default kind is used. The default kind can be affected by compiler options that affect the size of variables.

You can explicitly specify the data type of a scalar variable only once.

If no explicit data type specification appears, any variable with a name that begins with the letter in the range specified in the IMPLICIT statement becomes the data type of the variable.

Character type declaration statements specify that given variables represent character values with the length specified. For example, the following statements associate the variable names INLINE, NAME, and NUMBER with storage locations containing character data of lengths 72, 12, and 9, respectively:

```
CHARACTER(72) INLINE
CHARACTER NAME*12, NUMBER*9
```

In single subprograms, assumed-length character arguments can be used to process character strings with different lengths. The assumed-length character argument has its length specified with an asterisk, for example:

```
CHARACTER(*) CHARDUMMY
```

The argument CHARDUMMY assumes the length of the actual argument.

Type Declarations

Assumed-length character arguments
IMPLICIT statement
Declaration Statements for Character Types

Implicit Typing Rules

By default, all variables, named constants, and functions with names beginning with I, J, K, L, M, or N are assumed to be of default integer type. Variables, named constants, and functions with names beginning with any other letter are assumed to be of default real type. For example:

Real Variables	Integer Variables
ALPHA	JCOUNT
BETA	ITEM_1
TOTAL_NUM	NTOTAL

Names beginning with a dollar sign ($) are implicitly INTEGER.

You can override the default data type implied in a name by specifying data type in either an IMPLICIT statement or a type declaration statement.

See Also

Type Declarations

IMPLICIT statement

Arrays

An array is a set of scalar elements that have the same type and kind parameters. Any object that is declared with an array specification is an array. Arrays can be declared by using a type declaration statement, or by using a DIMENSION, COMMON, ALLOCATABLE, POINTER, or TARGET statement.

An array can be referenced by element (using subscripts), by section (using a section subscript list), or as a whole. A subscript list (appended to the array name) indicates which array element or array section is being referenced.

A section subscript list consists of subscripts, subscript triplets, or vector subscripts. At least one subscript in the list must be a subscript triplet or vector subscript.

When an array name without any subscripts appears in an intrinsic operation (for example, addition), the operation applies to the whole array (all elements in the array).

An array has the following properties:

- Data type

  An array can have any intrinsic or derived type. The data type of an array (like any other variable) is specified in a type declaration statement or implied by the first letter of its name. All elements of the array have the same type and kind parameters. If a value assigned to an individual array element is not the same as the type of the array, it is converted to the array's type.
- Rank

  The rank of an array is the number of dimensions in the array. An array can have up to 31 dimensions. A rank-one array represents a column of data (a vector), a rank-two array represents a table of data arranged in columns and rows (a matrix), a rank-three array represents a table of data on multiple pages (or planes), and so forth.
- Bounds

  Arrays have a lower and upper bound in each dimension. These bounds determine the range of values that can be used as subscripts for the dimension. The value of either bound can be positive, negative, or zero.

  The bounds of a dimension are defined in an array specification.
- Size

  The size of an array is the total number of elements in the array (the product of the array's extents).

  The *extent* is the total number of elements in a particular dimension. It is determined as follows: upper bound - lower bound + 1. If the value of any of an array's extents is zero, the array has a size of zero.
- Shape

  The shape of an array is determined by its rank and extents, and can be represented as a rank-one array (vector) where each element is the extent of the corresponding dimension.

  Two arrays with the same shape are said to be *conformable*. A scalar is conformable to an array of any shape.

The name and rank of an array must be specified when the array is declared. The extent of each dimension can be constant, but does not need to be. The extents can vary during program execution if the array is a dummy argument array, an automatic array, an array pointer, or an allocatable array.

A whole array is referenced by the array name. Individual elements in a named array are referenced by a scalar subscript or list of scalar subscripts (if there is more than one dimension). A section of a named array is referenced by a section subscript.

This section also discusses:

- Whole Arrays
- Array Elements
- Array Sections
- Array Constructors

Examples

The following are examples of valid array declarations:

```
DIMENSION    A(10, 2, 3)           ! DIMENSION statement
ALLOCATABLE  B(:, :)               ! ALLOCATABLE statement
POINTER      C(:, :, :)            ! POINTER statement
REAL, DIMENSION (2, 5) :: D        ! Type declaration with
                                   !     DIMENSION attribute
```

Consider the following array declaration:

```
INTEGER L(2:11,3)
```

The properties of array L are as follows:

Data type:	INTEGER
Rank:	2 (two dimensions)
Bounds:	First dimension: 2 to 11 Second dimension: 1 to 3
Size:	30; the product of the extents: 10 x 3
Shape:	(/10,3/) (or 10 by 3); a vector of the extents 10 and 3

The following example shows other valid ways to declare this array:

```
DIMENSION L(2:11,3)
INTEGER, DIMENSION(2:11,3) :: L
COMMON L(2:11,3)
```

The following example shows references to array elements, array sections, and a whole array:

```
REAL B(10)            ! Declares a rank-one array with 10 elements

INTEGER C(5,8)        ! Declares a rank-two array with 5 elements in
                      !    dimension one and 8 elements in dimension two
...
B(3) = 5.0            ! Reference to an array element
B(2:5) = 1.0          ! Reference to an array section consisting of
                      !    elements: B(2), B(3), B(4), B(5)
...
C(4,8) = I            ! Reference to an array element
C(1:3,3:4) = J        ! Reference to an array section consisting of
                      !    elements:  C(1,3) C(1,4)
                      !               C(2,3) C(2,4)
                      !               C(3,3) C(3,4)/

B = 99                ! Reference to a whole array consisting of
                      !    elements: B(1), B(2), B(3), B(4), B(5),
                      !    B(6), B(7), B(8), B(9), and B(10)
```

Whole Arrays

A *whole array* is a named array; it is either a named constant or a variable. It is referenced by using the array name (without any subscripts).

If a whole array appears in a nonexecutable statement, the statement applies to the entire array. For example:

```
INTEGER, DIMENSION(2:11,3) :: L   ! Specifies the type and
                                  !    dimensions of array L
```

If a whole array appears in an executable statement, the statement applies to all of the elements in the array. For example:

```
 L = 10       ! The value 10 is assigned to all the
              !   elements in array L
 WRITE *, L   ! Prints all the elements in array L
```

Array Elements

An *array element* is one of the scalar data items that make up an array. A subscript list (appended to the array or array component) determines which element is being referred to. A reference to an array element takes the following form:

array(*subscript-list*)

array	Is the name of the array.
subscript-list	Is a list of one or more subscripts separated by commas. The number of subscripts must equal the rank of the array. Each subscript must be a scalar integer (or other numeric) expression with a value that is within the bounds of its dimension.

Description

Each array element inherits the type, kind type parameter, and certain attributes (INTENT, PARAMETER, and TARGET) of the parent array. An array element cannot inherit the POINTER attribute.

If an array element is of type character, it can be followed by a substring range in parentheses; for example:

```
 ARRAY_D(1,2) (1:3)    ! Elements are substrings of length 3
```

However, by convention, such an object is considered to be a substring rather than an array element.

The following are some valid array element references for an array declared as REAL B(10,20): B(1,3), B(10,10), and B(5,8).

You can use functions and array elements as subscripts. For example:

```
REAL A(3, 3)
REAL B(3, 3), C(89), R
B(2, 2) = 4.5                       ! Assigns the value 4.5 to element B(2, 2)
R = 7.0
C(INT®*2 + 1) = 2.0                 ! Element 15 of C = 2.0
A(1,2) = B(INT(C(15)), INT(SQRT®))  ! Element A(1,2) = element B(2,2) = 4.5
```

For information on forms for array specifications, see Declaration Statements for Arrays.

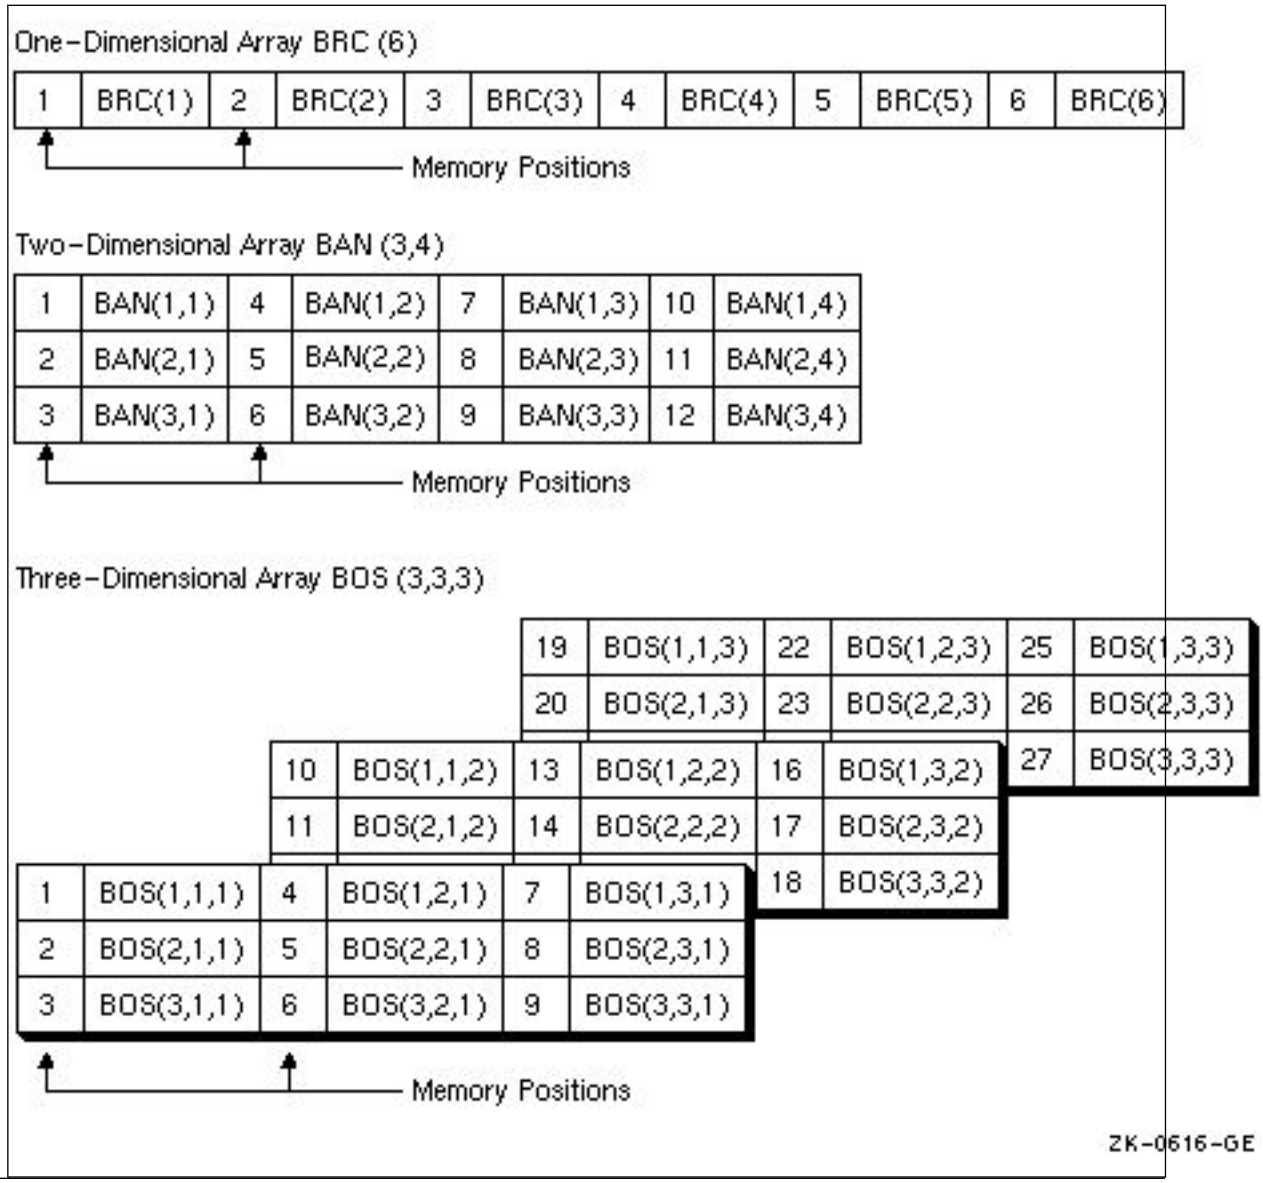
Array Element Order

The elements of an array form a sequence known as array element order. The position of an element in this sequence is its subscript order value.

The elements of an array are stored as a linear sequence of values. A one-dimensional array is stored with its first element in the first storage location and its last element in the last storage location of the sequence. A multidimensional array is stored so that the leftmost subscripts vary most rapidly. This is called the order of subscript progression.

The following figure shows array storage in one, two, and three dimensions:

Array Storage



For example, in two-dimensional array BAN, element BAN(1,2) has a subscript order value of 4; in three-dimensional array BOS, element BOS(1,1,1) has a subscript order value of 1.

In an array section, the subscript order of the elements is their order within the section itself. For example, if an array is declared as B(20), the section B(4:19:4) consists of elements B(4), B(8), B(12), and B(16). The subscript order value of B(4) in the array section is 1; the subscript order value of B(12) in the section is 3.

Array Sections

An *array section* is a portion of an array that is an array itself. It is an array subobject. A section subscript list (appended to the array or array component) determines which portion is being referred to. A reference to an array section takes the following form:

array(*sect-subscript-list*)

array	Is the name of the array.
sect-subscript-list	Is a list of one or more section subscripts (subscripts, subscript triplets, or vector subscripts) indicating a set of elements along a particular dimension. At least one of the items in the section subscript list must be a subscript triplet or vector subscript. A subscript triplet specifies array elements in increasing or decreasing order at a given stride. A vector subscript specifies elements in any order. Each subscript and subscript triplet must be a scalar integer (or other numeric) expression. Each vector subscript must be a rank-one integer expression.

Description

If *no* section subscript list is specified, the rank and shape of the array section is the same as the parent array.

Otherwise, the rank of the array section is the number of vector subscripts and subscript triplets that appear in the list. Its shape is a rank-one array where each element is the number of integer values in the sequence indicated by the corresponding subscript triplet or vector subscript.

If any of these sequences is empty, the array section has a size of zero. The subscript order of the elements of an array section is that of the array object that the array section represents.

Each array section inherits the type, kind type parameter, and certain attributes (INTENT, PARAMETER, and TARGET) of the parent array. An array section cannot inherit the POINTER attribute.

If an array (or array component) is of type character, it can be followed by a substring range in parentheses. Consider the following declaration:

```
CHARACTER(LEN=15) C(10,10)
```

In this case, an array section referenced as C(:,:) (1:3) is an array of shape (10,10), whose elements are substrings of length 3 of the corresponding elements of C.

The following shows valid references to array sections. Note that the syntax (/.../) denotes an array constructor.

```
REAL, DIMENSION(20) :: B
...
PRINT *, B(2:20:5)  ! The section consists of elements
                    !    B(2), B(7), B(12), and B(17)

K = (/3, 1, 4/)
B(K) = 0.0    ! Section B(K) is a rank-one array with shape (3) and
              !   size 3. (0.0 is assigned to B(1), B(3), and B(4).)
```

Subscript Triplets

A *subscript triplet* is a set of three values representing the lower bound of the array section, the upper bound of the array section, and the increment (stride) between them. It takes the following form:

[*first-bound*] : [*last-bound*] [:*stride*]

first-bound	Is a scalar integer (or other numeric) expression representing the first value in the subscript sequence. If omitted, the declared lower bound of the dimension is used.
last-bound	Is a scalar integer (or other numeric) expression representing the last value in the subscript sequence. If omitted, the declared upper bound of the dimension is used. When indicating sections of an assumed-size array, this subscript *must* be specified.
stride	Is a scalar integer (or other numeric) expression representing the increment between successive subscripts in the sequence. It must have a nonzero value. If it is omitted, it is assumed to be 1.

The stride has the following effects:

- If the stride is positive, the subscript range starts with the first subscript and is incremented by the value of the stride, until the largest value less than or equal to the second subscript is attained.

  For example, if an array has been declared as B(6,3,2), the array section specified as B(2:4,1:2,2) is a rank-two array with shape (3,2) and size 6. It consists of the following six elements:

```
B(2,1,2)    B(2,2,2)
B(3,1,2)    B(3,2,2)
B(4,1,2)    B(4,2,2)
```

  If the first subscript is greater than the second subscript, the range is empty.
- If the stride is negative, the subscript range starts with the value of the first subscript and is decremented by the absolute value of the stride, until the smallest value greater than or equal to the second subscript is attained.

  For example, if an array has been declared as A(15), the array section specified as A(10:3:-2) is a rank-one array with shape (4) and size 4. It consists of the following four elements:

```
A(10)
A(8)
A(6)
A(4)
```

  If the second subscript is greater than the first subscript, the range is empty.

If a range specified by the stride is empty, the array section has a size of zero.

A subscript in a subscript triplet need not be within the declared bounds for that dimension if all values used to select the array elements are within the declared bounds. For example, if an array has been declared as A(15), the array section specified as A(4:16:10) is valid. The section is a rank-one array with shape (2) and size 2. It consists of elements A(4) and A(14).

If the subscript triplet does not specify bounds or stride, but only a colon (:), the entire declared range for the dimension is used.

If you leave out all subscripts, the section defaults to the entire extent in that dimension. For example:

```
REAL A(10)
A(1:5:2) = 3.0   ! Sets elements A(1), A(3), A(5) to 3.0
A(:5:2) = 3.0    ! Same as the previous statement
                 !   because the lower bound defaults to 1
A(2::3) = 3.0    ! Sets elements A(2), A(5), A(8) to 3.0
                 ! The upper bound defaults to 10
A(7:9) = 3.0     ! Sets elements A(7), A(8), A(9) to 3.0
                 ! The stride defaults to 1
A(:) = 3.0       ! Same as A = 3.0; sets all elements of
                 !   A to 3.0
```

See Also

Array Sections

Vector Subscripts

A *vector subscript* is a one-dimensional (rank one) array of integer values (within the declared bounds for the dimension) that selects a section of a whole (parent) array. The elements in the section do not have to be in order and the section can contain duplicate values.

For example, A is a rank-two array of shape (4,6). B and C are rank-one arrays of shape (2) and (3), respectively, with the following values:

```
B = (/1,4/)           ! Syntax (/.../) denotes an array constructor
C = (/2,1,1/)         ! This constructor produces a many-one array section
```

Array section A(3,B) consists of elements A(3,1) and A(3,4). Array section A(C,1) consists of elements A(2,1), A(1,1), and A(1,1). Array section A(B,C) consists of the following elements:

```
A(1,2)    A(1,1)    A(1,1)
A(4,2)    A(4,1)    A(4,1)
```

An array section with a vector subscript that has two or more elements with the same value is called a *many-one array section*. For example:

```
REAL A(3, 3), B(4)
INTEGER K(4)
! Vector K has repeated values
K = (/3, 1, 1, 2/)
! Sets all elements of A to 5.0
A = 5.0
B = A(3, K)
```

The array section A(3,K) consists of the elements:

```
A(3, 3)  A(3, 1)  A(3, 1)  A(3, 2)
```

A many-one section must not appear on the left of the equal sign in an assignment statement, or as an input item in a READ statement.

The following assignments to C also show examples of vector subscripts:

```
INTEGER A(2), B(2), C(2)
...
B    = (/1,2/)
C(B) = A(B)
C    = A((/1,2/))
```

An array section with a vector subscript must not be any of the following:

- An internal file
- An actual argument associated with a dummy array that is defined or redefined (if the INTENT attribute is specified, it must be INTENT(IN))

- The target in a pointer assignment statement

If the sequence specified by the vector subscript is empty, the array section has a size of zero.

Array constructors

Array Constructors

An *array constructor* can be used to create and assign values to rank-one arrays and array constants. An array constructor takes one of the following forms:

(/*ac-spec*/)

[*ac-spec*]

ac-spec	Is one of the following: *type-spec* :: or [*type-spec* ::] *ac-value-list*
type-spec	Is a type specifier.
ac-value-list	Is a list of one or more expressions or implied-DO loops.

An implied-DO loop in an array constructor takes the following form:

(*ac-value-list*, *do-variable* = *expr*1, *expr*2 [,*expr*3])

do-variable	Is the name of a scalar integer variable. Its scope is that of the implied-DO loop.
expr	Is a scalar integer expression. The *expr1* and *expr2* specify a range of values for the loop; *expr3* specifies the stride. The *expr3* must be a nonzero value; if it is omitted, it is assumed to be 1.

Description

If *type-spec* is omitted, each *ac-value-list* expression must have the same type and kind type parameters, and the same length parameters. In this case, the array constructed has the same type as the *ac-value-list* expressions.

If *type-spec* appears, it specifies the type and type parameters of the array constructor. Each *ac-value-list* expression must be compatible with intrinsic assignment to a variable of this type and type parameters. Each value is converted to the type parameters of the array constructor in accordance with the rules of intrinsic assignment.

If *type-spec* specifies an intrinsic type, each *ac-value-list* expression must be of an intrinsic type that conforms with a variable of type type-spec.

If *type-spec* specifies a derived type, all *ac-value-list* expressions must be of that derived type and must have the same kind type parameter values as specified by *type-spec*.

If the sequence of values specified by the array constructor is empty (an empty array expression or the implied-DO loop produces no values), the rank-one array has a size of zero.

An *ac-value* is interpreted as follows:

Form of *ac-value*	Result
A scalar expression	Its value is an element of the new array.

Form of *ac-value*	Result
An array expression	The values of the elements in the expression (in array element order) are the corresponding sequence of elements in the new array.
An implied-DO loop	It is expanded to form a list of array elements under control of the DO variable (like a DO construct).

The following shows the three forms of an *ac-value*:

```
C1 = (/4,8,7,6/)                  ! A scalar expression
C2 = (/B(I, 1:5), B(I:J, 7:9)/)   ! An array expression
C3 = (/(I, I=1, 4)/)              ! An implied-DO loop
```

You can also mix these forms, for example:

```
C4 = (/4, A(1:5), (I, I=1, 4), 7/)
```

If every expression in an array constructor is a constant expression, the array constructor is a constant expression.

If *type-spec* is omitted, Intel® Fortran allows the numeric expressions to be of different kind types, but not different types. The resultant numeric array is the type and kind type of the first expression in the *ac-value-list*. For example:

```
 INTEGER, PARAMETER :: K(2) = [4, 8]
! The following line prints 4.000000       8.00000000000000
PRINT *, REAL (K(1), K(1)), REAL (K(2), K(2))
! The following line prints 4.000000       8.000000
PRINT *, [ (REAL (K(I), K(I)), I=1,20]
```

If *type-spec* is omitted, Intel® Fortran allows the character expressions to be of different character lengths. The length of the resultant character array is the maximum of the lengths of the individual character expressions. For example:

```
print *,len ( (/'a','ab','abc','d'/) )
print *,'++'//(/'a','ab','abc','d'/)//'--'
```

This causes the following to be displayed:

```
           3
++a  --++ab --++abc--++d  --
```

If an implied-DO loop is contained within another implied-DO loop (nested), they cannot have the same DO variable (*do-variable*).

To define arrays of more than one dimension, use the RESHAPE intrinsic function.

The following are alternative forms for array constructors:

- Square brackets (instead of parentheses and slashes) to enclose array constructors; for example, the following two array constructors are equivalent:

```
INTEGER C(4)
C = (/4,8,7,6/)
C = [4,8,7,6]
```

- A colon-separated triplet (instead of an implied-DO loop) to specify a range of values and a stride; for example, the following two array constructors are equivalent:

```
INTEGER D(3)
D = (/1:5:2/)              ! Triplet form - also [1:5:2]
D = (/(I, I=1, 5, 2)/)     ! implied-DO loop form
```

The stride is optional; it defaults to 1. For example, the following two array constructors are equivalent:

```
 INTEGER E(5)
 E = (/1:5/)              ! Triplet form with default stride – also [1:5]
 E = (/(I, I=1, 5)/)      ! implied-DO loop form
```

Examples

The following example shows an array constructor using an implied-DO loop:

```
 INTEGER ARRAY_C(10)
 ARRAY_C = (/(I, I=30, 48, 2)/)
```

The values of ARRAY_C are the even numbers 30 through 48.

Implied-DO expressions and values can be mixed in the value list of an array constructor. For example:

```
INTEGER A(10)
A = (/1, 0, (I, I = -1, -6, -1), -7, -8 /)
! Mixed values and implied-DO in value list.
```

This example sets the elements of A to the values, in order, 1, 0, -1, -2, -3, -4, -5, -6, -7, -8.

The following example shows an array constructor of derived type that uses a structure constructor:

```
TYPE EMPLOYEE
    INTEGER ID
    CHARACTER(LEN=30) NAME
END TYPE EMPLOYEE
TYPE(EMPLOYEE) CC_4T(4)
CC_4T = (/EMPLOYEE(2732,"JONES"), EMPLOYEE(0217,"LEE"),     &
           EMPLOYEE(1889,"RYAN"), EMPLOYEE(4339,"EMERSON")/)
```

The following example shows how the RESHAPE intrinsic function can be used to create a multidimensional array:

```
 E = (/2.3, 4.7, 6.6/)
 D = RESHAPE(SOURCE = (/3.5, (/2.0, 1.0/), E/), SHAPE = (/2,3/))
```

D is a rank-two array with shape (2,3) containing the following elements:

```
  3.5    1.0    4.7
  2.0    2.3    6.6
```

The following shows another example:

```
INTEGER B(2,3), C(8)
! Assign values to a (2,3) array.
B = RESHAPE((/1, 2, 3, 4, 5, 6/),(/2,3/))
! Convert B to a vector before assigning values to
! vector C.
C = (/ 0, RESHAPE(B,(/6/)), 7 /)
```

Consider the following derived-type definition:

```
TYPE EMPLOYEE
 INTEGER AGE
 CHARACTER (LEN = 60) NAME
END TYPE EMPLOYEE
```

The following equivalent lines use the above type to construct a derived-type array value:

```
(/ EMPLOYEE (45, 'OLIVER'), EMPLOYEE (30, 'ONEIL') /)
[EMPLOYEE (45, 'OLIVER'), EMPLOYEE (30, 'ONEIL')]
```

The following example shows an array constructor that specifies a length type parameter:

```
(/ CHARACTER(LEN=8) :: 'Andrews', 'Donahue', 'Dehenney' , 'Washington' /)
```

In this constructor, without the type specification, Intel® Fortran makes all of the array elements length 10, that is, as long as the longest character element.

Coarrays

Coarrays and synchronization constructs are defined by the Fortran 2008 Standard and extended by Fortran 2018. These constructs support parallel programming using a Single Program Multiple Data (SPMD) model. These features are not available on macOS* systems.

NOTE
32-bit coarrays are deprecated and will be removed in a future release.

You must specify compiler option `[Q]coarray` to enable coarrays in your program.

A Fortran program containing coarrays is interpreted as if it were replicated a fixed number of times and all copies were executed asynchronously.

Each replication is called an "image", and each image has its own set of data objects. The number of images is set at run-time, but it can also be set by a compiler option or an environment variable.

The array syntax of Fortran is extended with additional trailing subscripts in square brackets to provide a clear representation of references to data that is spread across images. References without square brackets are to local data, so source code that can run independently is uncluttered. Any appearance of square brackets indicates communication between images.

Usually, each image resides on one processor. However, several images may share a processor and one image can execute on a cluster.

To reference any array variable that is coindexed, a subscript list must be present. If no subscript list is present, then the coindexed object must be a scalar.

Examples

Consider the following statement:

```
real, dimension(500), codimension[*] :: a,b
```

This statement declares two objects `a` and `b`, each as a coarray. A coarray always has the same shape on each image. In this case, each image has two real coarrays of size 500.

Consider that an image executes the following statement:

```
a(:) = b(:)[q]
```

In this case, the coarray `b` on image `q` is copied into coarray `a` on the executing image.

Consider the coindexed reference `x[k]`. If `x` is a rank 1 array, this reference to `x` on image `k` is incorrect syntax: a subscript list must be present. The correct form is `x(:)[k]` to access the entire array `x` on image `k`. If `x` is a scalar, then the syntax `x[k]` is correct.

See Also

Image Control Statements
Coarrays
Using Coarrays

Image Selectors

An image selector determines the image index for a coindexed object. It takes the following form:

lbracket cosubscript-list [, STAT=*stat-var*] *rbracket*

lbracket	Is a left bracket "[". This is required.
cosubscript	Is a scalar integer expression. Its value must be within the cobounds for its codimension. The number of cosubscripts must be equal to the corank of the object. If the lower bound is not specified, it is assumed to be 1.
stat-var	(Optional) Is a scalar integer variable with an exponent range of at least 4 (KIND=2 or greater). *stat-var* cannot be coindexed.
rbracket	Is a right bracket "]". This is required.

Considering the cobounds and bounds, respectively, the cosubscript list in an image selector determines the image index in the same way that a subscript list in an array element determines the subscript order value.

An image selector must specify an image index value that is not greater than the number of images.

When a statement containing an image selector with STAT= specified is executed, *stat-var* becomes defined with value STAT_FAILED_IMAGE defined in the intrinsic module ISO_FORTRAN_ENV if the object referenced by the image selector is on a failed image. Otherwise, *stat-var* becomes defined with the value zero.

A *stat-var* in an image selector cannot depend on the evaluation of any other entity in the same statement. An expression cannot depend on the value of any *stat-var* that is specified in the same statement. The value of *stat-var* cannot depend on execution of any part of the statement, other than if the object is on a failed image.

Examples

Assume that there are 16 images and the coarray C is declared as follows:

```
REAL :: C(15)[5,*]
```

C(:)[1,4] is valid because it selects image 16, but C(:)[2,4] is invalid because it selects image 17.

C(1)[2, 1, STAT=istatus] will cause istatus to become defined with the value STAT_FAILED_IMAGE if image 6 has failed; otherwise, istatus becomes defined with the value zero.

Deferred-Coshape Coarrays

A deferred-coshape(allocatable) coarray has cobounds that are determined by allocation or argument association.

An allocatable coarray has the ALLOCATABLE attribute and a deferred-coshape specification.

A deferred-coshape specification is indicated by a colon (:).

The corank of an allocatable coarray is equal to the number of colons in its deferred-coshape specification.

The cobounds of an unallocated allocatable coarray are undefined. No part of such a coarray can be referenced or defined; however, the coarray may appear as an argument to an intrinsic inquiry function.

The cobounds of an allocated allocatable coarray are those specified when the coarray is allocated.

The cobounds of an allocatable coarray are unaffected by any subsequent redefinition or undefinition of the variables on which the cobounds' expressions depend.

See Also

Coarrays

Explicit-Coshape Coarrays

An explicit-coshape coarray is a named coarray that has its corank and cobounds declared by an explicit-coshape specification.

An explicit-coshape specification takes the following form:

[[*lower-cobound*:] *upper-cobound*,] ... [*lower-cobound*:] *

lc	Is a specification expression indicating the lower cobound of the coarray. The expression can have a positive, negative, or zero value. If necessary, the value is converted to integer type. If the lower bound is not specified, it is assumed to be 1.
uc	Is a specification expression indicating the upper cobound of the coarray. The expression can have a positive, negative, or zero value. If necessary, the value is converted to integer type. The upper cobound must not be less than the lower cobound (*lc*), if specified.

A nonallocatable coarray must have a coarray specification (coarray-spec) that is an explicit-coshape specification.

The corank is equal to one plus the number of upper cobounds.

A lower cobound or upper cobound that is not a constant expression must appear only in a subprogram or interface body.

If an explicit-coshape coarray is a local variable of a subprogram and has cobounds that are not constant expressions, the cobounds are determined on entry to a procedure defined by the subprogram, by evaluating the cobounds expressions . The cobounds of such a coarray are unaffected by the redefinition or undefinition of any variable during execution of the procedure.

The values of each lower cobound and upper cobound determine the cobounds of the coarray along a particular codimension. The cosubscript range of the coarray in that codimension is the set of integer values between and including the lower and upper cobounds.

Examples

The following are examples of variables with coarray specifications (coarray-specs):

```
A [*]
AA [2:*]
B [2, 3, *]
C [3:5, -2:7, *]
```

Referencing Coarray Images

Data on other images is normally referenced by cosubscripts enclosed in square brackets.

For coarray images, each set of cosubscripts maps to an image index, which is an integer between one and the number of images, in the same way as a set of array subscripts maps to a position in array element order.

To find the image index for each image, specify intrinsic function THIS_IMAGE() with no arguments.

To find the set of subscript indices that corresponds to the current image for a coarray z, specify THIS_IMAGE(z).

To find the image index that corresponds to a set of cosubscript indices sub for a coarray z, specify intrinsic function IMAGE_INDEX(z,sub).

To find the number of images, specify intrinsic function NUM_IMAGES.

Specifying Data Objects for Coarray Images

Each image has its own set of data objects, all of which can be accessed in the normal way.

The rank, bounds, extents, size, and shape of a whole coarray are provided by the data in parentheses in its declaration or allocation. Its corank, cobounds, and coextents are provided by the data in square brackets in its declaration or allocation. Any subobject of the coarray that is a coarray has the same corank, cobounds, and coextents. The cosize of a coarray is always equal to the number of images.

Objects can be declared with codimensions in square brackets immediately following dimensions in parentheses or in place of them, for example:

```
real :: a[*], d[*]                              ! Scalar coarrays
real, dimension(50), codimension[50,*] :: x     ! An array coarray
integer :: n(100)[*]
character :: b(40)[40,0:*]
type(para) :: w[30,*]
```

Unless the coarray is allocatable, the form for the dimensions in square brackets is the same as that for dimensions in parentheses in an assumed-size array.

The total number of subscripts plus cosubscripts is limited to 31. Note that the Fortran 2008 Standard limits the total number of subscripts plus cosubscripts to 15.

You can address a coarray on another image by using subscripts in square brackets following any subscripts in parentheses, for example:

```
b(6)[4,7] = n(6)[4]
e[4] = c
b(:)[3,4] = c[2]
```

Any object whose designator includes square brackets is called a coindexed object. Each subscript in square brackets must be a scalar integer expression.

Subscripts in parentheses must be used whenever the parent array has nonzero rank. For example, for a(:)[2,3], you cannot specify a[2,3].

Variable-Definition Context

A variable can appear in different contexts that imply definition or undefinition of the variable. A reference to a function that returns a data pointer is permitted in such variable-definition contexts.

When a function returns a data pointer, that pointer is always associated with a variable that has the TARGET attribute, either by pointer assignment or by allocation. If a reference to a function that returns a data pointer appears in a variable-definition context, the definable target (with which the function result is associated) is the variable that becomes defined or undefined.

This section describes the different variable-definition contexts in which a function reference returning a data pointer can be used. It also describes the contexts in which data pointer function references are not allowed.

Assignment Statement

Function references returning a data pointer can be used on the left-hand side of an assignment statement. References to type bound and generic procedures are also permitted on the left-hand side of an intrinsic assignment. If the variable on the left-hand side is polymorphic, it must be an allocatable. Therefore, a function returning a polymorphic pointer cannot be used on the left-hand side.

In the following example, function STORAGE returns a data pointer to either the module variable OUTSIDE or to an element of VAR into which a value is stored:

```
MODULE TMOD
 PUBLIC

 INTEGER, PARAMETER :: N = 10
 INTEGER, TARGET    :: VAR(N)
 INTEGER, TARGET    :: OUTSIDE
 CONTAINS
 FUNCTION STORAGE(KEY) RESULT(LOC)
   INTEGER, INTENT(IN) :: KEY
   INTEGER, POINTER    :: LOC

   IF( KEY .LT. 1 .OR. KEY .GE. N ) THEN
     LOC=> OUTSIDE
   ELSE
     LOC => VAR(KEY)
   ENDIF
 END FUNCTION
END MODULE

PROGRAM MAIN
  USE TMOD
  OUTSIDE = -1
  STORAGE(1) = 11
  STORAGE(0) = 0
  PRINT *, VAR(1), OUTSIDE    ! prints 11, 0
END
```

The following example shows generic resolution on the left-hand side of an assignment statement:

```
MODULE MYMODULE
    TYPE :: VEC
        INTEGER :: X(3)
    CONTAINS
        GENERIC   :: GET => GETELEMENT, GETARRAY
        PROCEDURE :: GETELEMENT
        PROCEDURE :: GETARRAY
    END TYPE VEC
    CONTAINS
        FUNCTION GETELEMENT( THIS, EL ) RESULT( P )
            IMPLICIT NONE
            CLASS(VEC), TARGET :: THIS
            INTEGER, INTENT(IN) :: EL
            INTEGER, POINTER :: P
            P => THIS%X(EL)
        END FUNCTION GETELEMENT

        FUNCTION GETARRAY( THIS ) RESULT( P )
            IMPLICIT NONE
            CLASS(VEC), TARGET :: THIS
            INTEGER, POINTER :: P(:) ! array pointer
```

```
            P => THIS%X
        END FUNCTION GETARRAY
END MODULE MYMODULE

PROGRAM TEST
   USE MYMODULE
   IMPLICIT NONE
   TYPE(VEC) :: MYVEC
   INTEGER   :: Y(3)
   MYVEC%X = [1,2,3]
   Y = [6,7,8]

   ! expected output 1 2 1 2 3
   WRITE(6,*) MYVEC%GET(1), MYVEC%GET(2), MYVEC%GET()

   ! change any array element
   MYVEC%GET(1) = 4
   MYVEC%GET(2) = 5
   MYVEC%GET(3) = 6

   ! check modified values
   ! expected output 4 5 4 5 6
   WRITE(6,*) MYVEC%GET(1), MYVEC%GET(2), MYVEC%GET()

   MYVEC%GET() = Y          ! array pointer returned

   ! check modified values
   WRITE(6,*)  MYVEC%GET()  ! expected output 6 7 8
END PROGRAM TEST
```

Argument Association

A function reference returning a data pointer can be used as an actual argument in a reference to a procedure with an explicit interface. If the corresponding dummy argument has the INTENT (OUT) or INTENT (INOUT) attribute, then the pointer function is used in a variable definition context.

The following example uses the function STORAGE, which was defined in the above section "Assignment Statement":

```
FUNCTION STORAGE(KEY) RESULT(LOC)
   INTEGER, INTENT(IN) :: KEY
   INTEGER, POINTER    :: LOC
..
END FUNCTION
..
STORAGE(2) = 10
CALL CHANGE_VAL(STORAGE(2)) ! pass storage(2) as actual argument
PRINT *, VAR(2)             ! prints 50
..
SUBROUTINE CHANGE_VAL(X)
  INTEGER, INTENT(OUT) :: X
  X = X*5
END SUBROUTINE CHANGE_VAL
```

The following example shows that the target of the function pointer can get modified inside the subroutine without using the dummy argument corresponding to the function reference:

```
MODULE M200C2
  INTEGER, TARGET :: X = 42
CONTAINS
  FUNCTION FX()
    INTEGER, POINTER :: FX
    FX => X
  END FUNCTION
END MODULE

PROGRAM Q1
  USE M200C2
  CALL TEST(X, FX())
  ! note that corresponding dummy is not INTENT (OUT) or INTENT(INOUT).
  ! FX() is not used in a variable definition context but it still
  !   denotes a variable.
  CONTAINS
  SUBROUTINE TEST(A, B)
  INTEGER, TARGET :: B
    A = A*10
    PRINT *, A, B               !  prints 420 420
  END SUBROUTINE
END PROGRAM
```

SELECT RANK, SELECT TYPE, and ASSOCIATE Construct

A pointer function reference can appear as a variable that is the selector in a SELECT RANK, SELECT TYPE, or ASSOCIATE construct and the associate name of that construct can appear in a variable-definition context. For example:

```
PROGRAM MAIN
    INTEGER, TARGET :: DATA = 123

    ASSOCIATE (ALIAS => FX1())
        ALIAS = 456
        PRINT *, ALIAS, DATA     ! prints 456 456
    END ASSOCIATE

    SELECT TYPE (ALIAS =>FX2())
        TYPE IS (INTEGER)
          ALIAS = 789
          PRINT *, ALIAS, DATA   ! prints 789 789
    END SELECT

    CONTAINS
    FUNCTION FX1()
        INTEGER, POINTER :: FX1
        FX1 => DATA
    END FUNCTION FX1
    FUNCTION FX2()
        CLASS(*),POINTER :: FX2
        FX2 => DATA
    END FUNCTION FX2
END PROGRAM MAIN
```

In the following example, FX() in the ASSOCIATE is a variable and every reference to ALIAS is a reference to the associated variable, so the assignment also changes the value of ALIAS:

```
PROGRAM MAIN
    INTEGER, TARGET :: DATA = 123

    ASSOCIATE (ALIAS => FX1())
        DATA = 0
        PRINT *, ALIAS, DATA     ! prints 0 0
    END ASSOCIATE

    SELECT TYPE (ALIAS => FX2())
        TYPE IS (INTEGER)
          DATA = 1
          PRINT *, ALIAS, DATA   ! prints 1 1
    END SELECT

    CONTAINS

    FUNCTION FX1 ()
        INTEGER, POINTER :: FX1
        FX1 => DATA
    END FUNCTION FX1

    FUNCTION FX2()
        CLASS(*),POINTER :: FX2
        FX2 => DATA
    END FUNCTION FX2

END PROGRAM MAIN
```

Input/Output Statements

A pointer function reference can be used as an input item in a READ statement.

A function reference returning a character pointer can be used as an internal file variable in a WRITE statement.

A scalar integer pointer function reference can be an IOSTAT= or a SIZE= specifier in an input/output statement. A scalar character pointer function reference can be an IOMSG= specifier in an input/output statement.

A function returning a scalar pointer, whose datatype matches the specifier, can be specified in an INQUIRE statement except for the three specifiers FILE=, ID=, and UNIT=.

A function returning a scalar integer pointer can be a NEWUNIT= specifier in an OPEN statement.

Consider the following example:

```
...
    CHARACTER(50), TARGET :: V(33)
    INTEGER, TARGET :: I
    ..
    FUNCTION RET_CHAR(INDEX) RESULT (DCV)
      CHARACTER(50), POINTER :: DCV
      INTEGER :: INDEX
      DCV => V(INDEX)
    END FUNCTION
    FUNCTION RET_INT() RESULT (P)
      INTEGER, POINTER :: P
      P => I
```

```
    END FUNCTION
  ...
! an input item in a read stmt
    READ (6, *) RET_INT()
    READ  10, RET_INT()

! an internal file variable in a write stmt
    WRITE  (RET_CHAR(10), FMT=*) 666

! an IOSTAT=, SIZE=, or IOMSG= specifier in an I/O statement
    READ (10, FMT=*, IOSTAT=RET_INT(), SIZE=RET_INT(), &
          IOMSG=RET_CHAR(6) ) STR

! a specifier in an inquire statement except FILE=, ID=, and UNIT=
    OPEN(NEWUNIT = NUM, FILE = 'A.TXT', ACTION = 'READ')
    INQUIRE(NUM,                &
    ACCESS = RET_CHAR(2),       &
    EXIST = RET_CHAR(10),       &
    ID = 13,                    &
    IOSTAT = RET_CHAR(14),      &
    SIZE = RET_CHAR(30))
    CLOSE(NUM, STATUS = 'DELETE')

! a NEWUNIT= SPECIFIER in an OPEN statement
    OPEN(NEWUNIT = RET_INT(1), STATUS = 'SCRATCH')
    CLOSE(RET_INT(1), STATUS = 'DELETE') ! allowed on CLOSE
```

STAT=, ERRMSG=, and ACQUIRED_LOCK= Specifiers

A scalar integer pointer function reference can be used as a STAT= variable. A scalar character pointer function reference can be used as an ERRMSG= variable. STAT= and ERRMSG= are allowed in EVENT POST, EVENT WAIT, SYNC ALL, SYNC IMAGES, SYNC MEMORY, LOCK, UNLOCK, ALLOCATE, and DEALLOCATE statements. A scalar logical pointer function reference can be an ACQUIRED_LOCK= specifier in a LOCK statement.

The following example uses RET_CHAR and RET_INT, which were defined in the above section "Input/Output Statements":

```
    TYPE(EVENT_TYPE) :: ET[*]
    TYPE(LOCK_TYPE) :: LT[*]
    INTEGER, POINTER     :: AR(:)
    ALLOCATE(AR(2), STAT=RET_INT())
    DEALLOCATE(AR, STAT=RET_INT())

    EVENT POST (EV[THIS_IMAGE() + 1], STAT=RET_INT(), ERRMSG=RET_CHAR())
    EVENT WAIT(EV, STAT=RET_INT(), ERRMSG=RET_CHAR())
    LOCK(LT, ACQUIRED_LOCK=GET_LOGICAL(), STAT=RET_INT(), &
    ERRMSG=RET_CHAR())
    UNLOCK(LT, STAT=RET_INT(), ERRMSG=RET_CHAR())
    SYNC IMAGES(*,STAT=RET_INT(), ERRMSG=RET_CHAR())
    SYNC ALL(STAT=RET_INT(), ERRMSG=RET_CHAR())
    SYNC MEMORY(STAT=RET_INT(), ERRMSG=RET_CHAR())
```

Execution of EVENT POST and EVENT WAIT statements

An event variable of type EVENT_TYPE from the ISO_FORTRAN_ENV module becomes defined by the successful execution of an EVENT POST or an EVENT WAIT statement.

Execution of a LOCK or UNLOCK statement

A lock variable of LOCK_TYPE from the ISO_FORTRAN_ENV module becomes defined by the successful execution of an UNLOCK statement, or a LOCK statement without an ACQUIRED_LOCK= specifier. Successful execution of a LOCK statement with an ACQUIRED_LOCK= specifier causes the specified logical variable to become defined. If it is defined with the value true, the lock variable in the LOCK statement also becomes defined.

Disallowed Contexts

The Fortran Standard defines both a "variable" and a "variable name". For function F, F is a variable name; F(7) is a function. If F returns a data pointer, F(7) is a variable and can be used in a variable-definition context.

For the following variable-definition contexts, the Fortran Standard specifies that a "variable name" must be used and not a "variable":

- The pointer object in a NULLIFY statement
- A data pointer object or procedure pointer object in a pointer assignment statement
- The DO variable in a DO statement or an implied DO construct
- A variable name in a NAMELIST statement if the NAMELIST group name appears in a NML= specifier in a READ statement
- The object in an ALLOCATE or DEALLOCATE statement
- An event variable in an EVENT POST or EVENT WAIT statement
- The lock variable in a LOCK or UNLOCK statement

A function reference can return a pointer to any data object, even one that cannot be stored into, for example, a USE associated PROTECTed object or a constant. This will not be caught at compile time. It is possible that the target of the pointer function is a local variable from a different subprogram or a private USE associated variable, in which case the pointer returned has an undefined association status.

A More Complex Example

The following example has pointer functions that return data pointers to parameterized derived type objects. The pointer function results are automatic objects whose length type parameters depend on the dummy arguments:

```
MODULE TMOD
  PUBLIC
  TYPE PDT(K, L)
    INTEGER, KIND :: K
    INTEGER, LEN :: L
    INTEGER :: FIELD(L)
  END TYPE PDT
END MODULE
PROGRAM MAIN
    USE TMOD
    IMPLICIT NONE
    TYPE(PDT(4,2)), TARGET :: PDTOBJ1, OBJ
    TYPE(PDT(2,2)), POINTER :: ACTARG
    CHARACTER(10), TARGET :: C1

    BAR() = PDT(4,2)((/5,3/))
    PRINT *, PDTOBJ1%FIELD            ! prints 5 3

    AUTO_RES(ACTARG) = PDT(4,2)((/6,4/))
    PRINT *, PDTOBJ1%FIELD            ! prints 6 4

    AUTO_CHAR(10) = "TEST"
```

```
    PRINT *, C1                       ! prints TEST
    CONTAINS
    FUNCTION BAR() RESULT(LOC)
        TYPE(PDT(4,2)), POINTER :: LOC
        LOC => PDTOBJ1
    END FUNCTION
    FUNCTION AUTO_CHAR(DUM1) RESULT(LOC)
         INTEGER, INTENT(IN) :: DUM1
         CHARACTER(DUM1), POINTER :: LOC
         LOC => C1
    END FUNCTION

    FUNCTION AUTO_RES(DUM1) RESULT(LOC)
         TYPE(PDT(4,:)), POINTER, INTENT(IN) :: DUM1
         TYPE(PDT(4,DUM1%L)), POINTER :: LOC
         LOC => PDTOBJ1
    END FUNCTION
END PROGRAM
```

Expressions and Assignment Statements

An expression represents either a data reference or a computation, and is formed from operators, operands, and parentheses. The result of an expression is either a scalar value or an array of scalar values.

An assignment causes variables to be defined or redefined.

For more information, see the individual topics in this section.

Expressions

An expression represents either a data reference or a computation, and is formed from operators, operands, and parentheses. The result of an expression is either a scalar value or an array of scalar values.

If the value of an expression is of intrinsic type, it has a kind type parameter. (If the value is of intrinsic type CHARACTER, it also has a length parameter.) If the value of an expression is of derived type, it has no kind type parameter.

An operand is a scalar or array. An operator can be either intrinsic or defined. An intrinsic operator is known to the compiler and is always available to any program unit. A defined operator is described explicitly by a user in a function subprogram and is available to each program unit that uses the subprogram.

The simplest form of an expression (a primary) can be any of the following:

- A constant; for example, 4.2
- A subobject of a constant; for example, 'LMNOP' (2:4)
- A variable; for example, VAR_1
- A structure constructor; for example, EMPLOYEE(3472, "JOHN DOE")
- An array constructor; for example, (/12.0,16.0/)
- A function reference; for example, COS(X)
- Another expression in parentheses; for example, (I+5)

Any variable or function reference used as an operand in an expression must be defined at the time the reference is executed. If the operand is a pointer, it must be associated with a target object that is defined. An integer operand must be defined with an integer value rather than a statement label value. All of the characters in a character data object reference must be defined.

When a reference to an array or an array section is made, all of the selected elements must be defined. When a structure is referenced, all of the components must be defined.

In an expression that has intrinsic operators with an array as an operand, the operation is performed on each element of the array. In expressions with more than one array operand, the arrays must be conformable (they must have the same shape). The operation is applied to corresponding elements of the arrays, and the result is an array of the same shape (the same rank and extents) as the operands.

In an expression that has intrinsic operators with a pointer as an operand, the operation is performed on the value of the target associated with the pointer.

For defined operators, operations on arrays and pointers are determined by the procedure defining the operation.

A scalar is conformable with any array. If one operand of an expression is an array and another operand is a scalar, it is as if the value of the scalar were replicated to form an array of the same shape as the array operand. The result is an array of the same shape as the array operand.

The following sections describe numeric, character, relational, and logical expressions; defined operations; a summary of operator precedence; and initialization and specification expressions.

POINTER statement for details on pointers

Numeric Expressions

Numeric expressions express numeric computations, and are formed with numeric operands and numeric operators. The evaluation of a numeric operation yields a single numeric value.

The term *numeric* includes logical data, because logical data is treated as integer data when used in a numeric context. The default for .TRUE. is -1; .FALSE. is 0. Note that the default can change if compiler option fpscomp logicals is used.

Numeric operators specify computations to be performed on the values of numeric operands. The result is a scalar numeric value or an array whose elements are scalar numeric values. The following are numeric operators:

Operator	Function
**	Exponentiation
*	Multiplication
/	Division
+	Addition or unary plus (identity)
-	Subtraction or unary minus (negation)

Unary operators operate on a single operand. *Binary operators* operate on a pair of operands. The plus and minus operators can be unary or binary. When they are unary operators, the plus or minus operators precede a single operand and denote a positive (identity) or negative (negation) value, respectively. The exponentiation, multiplication, and division operators are binary operators.

Valid numeric operations must have results that are defined by the arithmetic used by the processor. For example, raising a negative-valued base to a real power is invalid.

Numeric expressions are evaluated in an order determined by a precedence associated with each operator, as follows (see also Summary of Operator Precedence):

Operator	Precedence
**	Highest
* and /	.
Unary + and -	.
Binary + and -	Lowest

Operators with equal precedence are evaluated in left-to-right order. However, exponentiation is evaluated from right to left. For example, A**B**C is evaluated as A**(B**C). B**C is evaluated first, then A is raised to the resulting power.

Normally, two operators cannot appear together. However, Intel® Fortran allows two consecutive operators if the second operator is a plus or minus.

Examples

In the following example, the exponentiation operator is evaluated first because it takes precedence over the multiplication operator:

`A**B*C` is evaluated as `(A**B)*C`

Ordinarily, the exponentiation operator would be evaluated first in the following example. However, because Intel Fortran allows the combination of the exponentiation and minus operators, the exponentiation operator is not evaluated until the minus operator is evaluated:

`A**-B*C` is evaluated as `A**(-(B*C))`

Note that the multiplication operator is evaluated first, since it takes precedence over the minus operator.

When consecutive operators are used with constants, the unary plus or minus before the constant is treated the same as any other operator. This can produce unexpected results. In the following example, the multiplication operator is evaluated first, since it takes precedence over the minus operator:

`X/-15.0*Y` is evaluated as `X/-(15.0*Y)`

fpscomp compiler option

Using Parentheses in Numeric Expressions

You can use parentheses to force a particular order of evaluation. When part of an expression is enclosed in parentheses, that part is evaluated first. The resulting value is used in the evaluation of the remainder of the expression.

In the following examples, the numbers below the operators indicate a possible order of evaluation. Alternative evaluation orders are possible in the first three examples because they contain operators of equal precedence that are not enclosed in parentheses. In these cases, the compiler is free to evaluate operators of equal precedence in any order, as long as the result is the same as the result gained by the algebraic left-to-right order of evaluation.

```
    4 + 3 * 2 - 6/2   = 7
      ^   ^   ^  ^
      2   1   4  3
    (4 + 3) * 2 - 6/2   = 11
       ^    ^   ^  ^
       1    2   4  3
    (4 + 3 * 2 - 6)/2   = 2
       ^   ^   ^   ^
       2   1   3   4
```

```
((4 + 3) * 2 - 6)/2   = 4
    ^    ^   ^   ^
    1    2   3   4
```

Expressions within parentheses are evaluated according to the normal order of precedence. In expressions containing nested parentheses, the innermost parentheses are evaluated first.

Nonessential parentheses do not affect expression evaluation, as shown in the following example:

```
4 + (3 * 2) - (6/2)
```

However, using parentheses to specify the evaluation order is often important in high-accuracy numerical computations. In such computations, evaluation orders that are algebraically equivalent may not be computationally equivalent when processed by a computer (because of the way intermediate results are rounded off).

Parentheses can be used in argument lists to force a given argument to be treated as an expression, rather than as the address of a memory item.

Data Type of Numeric Expressions

If every operand in a numeric expression is of the same data type, the result is also of that type.

If operands of different data types are combined in an expression, the evaluation of that expression and the data type of the resulting value depend on the ranking associated with each data type. The following table shows the ranking assigned to each data type:

Data Type	Ranking
LOGICAL(1) and BYTE	Lowest
LOGICAL(2)	.
LOGICAL(4)	.
LOGICAL(8)	.
INTEGER(1)	.
INTEGER(2)	.
INTEGER(4)	.
INTEGER(8)	.
REAL(4)	.
REAL(8)[1]	.
REAL(16)	.
COMPLEX(4)	.
COMPLEX(8)[2]	.
COMPLEX(16)	Highest

[1] DOUBLE PRECISION

[2] DOUBLE COMPLEX

The data type of the value produced by an operation on two numeric operands of different data types is the data type of the highest-ranking operand in the operation. For example, the value resulting from an operation on an integer and a real operand is of real type. However, an operation involving a COMPLEX(4) or COMPLEX(8) data type and a DOUBLE PRECISION data type produces a COMPLEX(8) result.

The data type of an expression is the data type of the result of the last operation in that expression, and is determined according to the following conventions:

- Integer operations: Integer operations are performed only on integer operands. (Logical entities used in a numeric context are treated as integers.) In integer arithmetic, any fraction resulting from division is truncated, not rounded. For example, the result of `9/10` is 0, not 1.
- Real operations: Real operations are performed only on real operands or combinations of real, integer, and logical operands. Any integer operands present are converted to real data type by giving each a fractional part equal to zero. The expression is then evaluated using real arithmetic. However, in the statement `Y = (I /J)*X`, an integer division operation is performed on I and J, and a real multiplication is performed on that result and X.

  If one operand is a higher-precision real (REAL(8) or REAL(16)) type, the other operand is converted to that higher-precision real type before the expression is evaluated.

  When a single-precision real operand is converted to a double-precision real operand, low-order binary digits are set to zero. This conversion does not increase accuracy; conversion of a decimal number does not produce a succession of decimal zeros. For example, a REAL variable having the value `0.3333333` is converted to approximately `0.3333331346511184D0`. It is not converted to either `0.3333330000000000D0` or `0.3333333333333333D0`.
- Complex operations: In operations that contain any complex operands, integer operands are converted to real type, as previously described. The resulting single-precision or double-precision operand is designated as the real part of a complex number and the imaginary part is assigned a value of zero. The expression is then evaluated using complex arithmetic and the resulting value is of complex type. Operations involving a COMPLEX(4) or COMPLEX(8) operand and a DOUBLE PRECISION operand are performed as COMPLEX(8) operations; the DOUBLE PRECISION operand is not rounded.

These rules also generally apply to numeric operations in which one of the operands is a constant. However, if a real or complex constant is used in a higher-precision expression, additional precision will be retained for the constant. The effect is as if a DOUBLE PRECISION (REAL(8)) or REAL(16) representation of the constant were given. For example, the expression `1.0D0 + 0.3333333` is treated as if it is `1.0D0 + dble(0.3333333)`.

Character Expressions

A character expression consists of a character operator (//) that concatenates two operands of type character. The evaluation of a character expression produces a single value of that type.

The result of a character expression is a character string whose value is the value of the left character operand concatenated to the value of the right operand. The length of a character expression is the sum of the lengths of the values of the operands. For example, the value of the character expression `'AB'//'CDE'` is `'ABCDE'`, which has a length of five.

Parentheses do not affect the evaluation of a character expression; for example, the following character expressions are equivalent:

```
('ABC'//'DE')//'F'
'ABC'//('DE'//'F')
'ABC'//'DE'//'F'
```

Each of these expressions has the value `' ABCDEF'`.

If a character operand in a character expression contains blanks, the blanks are included in the value of the character expression. For example, `'ABC '//'D E'//'F '` has a value of `'ABC D EF '`.

Relational Expressions

A *relational expression* consists of two or more expressions whose values are compared to determine whether the relationship stated by the relational operator is satisfied. The following are relational operators:

Operator	Relationship
.LT. or <	Less than
.LE. or <=	Less than or equal to
.EQ. or ==	Equal to
.NE. or /=	Not equal to
.GT. or >	Greater than
.GE. or >=	Greater than or equal to

The result of the relational expression is .TRUE. if the relation specified by the operator is satisfied; the result is .FALSE. if the relation specified by the operator is not satisfied.

Relational operators are of equal precedence. Numeric operators and the character operator // have a higher precedence than relational operators.

In a numeric relational expression, the operands are numeric expressions. Consider the following example:

```
APPLE+PEACH > PEAR+ORANGE
```

This expression states that the sum of APPLE and PEACH is greater than the sum of PEAR and ORANGE. If this relationship is valid, the value of the expression is .TRUE.; if not, the value is .FALSE.

Operands of type complex can only be compared using the equal operator (== or .EQ.) or the not equal operator (/= or .NE.). Complex entities are equal if their corresponding real and imaginary parts are both equal.

In a character relational expression, the operands are character expressions. In character relational expressions, less than (< or .LT.) means the character value precedes in the ASCII collating sequence, and greater than (> or .GT.) means the character value follows in the ASCII collating sequence. For example:

```
'AB'//'ZZZ' .LT. 'CCCCC'
```

This expression states that `'ABZZZ'` is less than `'CCCCC'`. In this case, the relation specified by the operator is satisfied, so the result is .TRUE..

Character operands are compared one character at a time, in order, starting with the first character of each operand. If the two character operands are not the same length, the shorter one is padded on the right with blanks until the lengths are equal; for example:

```
'ABC' .EQ. 'ABC  '
'AB' .LT. 'C'
```

The first relational expression has the value .TRUE. even though the lengths of the expressions are not equal, and the second has the value .TRUE. even though `'AB'` is longer than `'C'`.

A relational expression can compare two numeric expressions of different data types. In this case, the value of the expression with the lower-ranking data type is converted to the higher-ranking data type before the comparison is made.

Data Type of Numeric Expressions

Logical Expressions

A logical expression consists of one or more logical operators and logical, numeric, or relational operands. The following are logical operators:

Operator	Example	Meaning
.AND.	`A .AND. B`	Logical conjunction: the expression is true if both A and B are true.
.OR.	`A .OR. B`	Logical disjunction (inclusive OR): the expression is true if either A, B, or both, are true.
.NEQV.	`A .NEQV. B`	Logical inequivalence (exclusive OR): the expression is true if either A or B is true, but false if both are true.
.XOR.	`A .XOR. B`	Same as .NEQV.
.EQV.	`A .EQV. B`	Logical equivalence: the expression is true if both A and B are true, or both are false.
.NOT.[1]	`.NOT. A`	Logical negation: the expression is true if A is false and false if A is true.

[1] .NOT. is a unary operator.

Periods cannot appear consecutively except when the second operator is .NOT. For example, the following logical expression is valid:

```
A+B/(A-1) .AND. .NOT. D+B/(D-1)
```

Data Types Resulting from Logical Operations

Logical operations on logical operands produce single logical values (.TRUE. or .FALSE.) of logical type.

Logical operations on integers produce single values of integer type. The operation is carried out bit-by-bit on corresponding bits of the internal (binary) representation of the integer operands.

Logical operations on a combination of integer and logical values also produce single values of integer type. The operation first converts logical values to integers, then operates as it does with integers.

Logical operations cannot be performed on other data types.

Evaluation of Logical Expressions

Logical expressions are evaluated according to the precedence of their operators. Consider the following expression:

```
A*B+C*ABC == X*Y+DM/ZZ .AND. .NOT. K*B > TT
```

This expression is evaluated in the following sequence:

```
(((A*B)+(C*ABC)) == ((X*Y)+(DM/ZZ))) .AND. (.NOT. ((K*B) > TT))
```

As with numeric expressions, you can use parentheses to alter the sequence of evaluation.

When operators have equal precedence, the compiler can evaluate them in any order, as long as the result is the same as the result gained by the algebraic left-to-right order of evaluation (except for exponentiation, which is evaluated from right to left).

You should not write logical expressions whose results might depend on the evaluation order of subexpressions. The compiler is free to evaluate subexpressions in any order. In the following example, either (A(I)+1.0) or B(I)*2.0 could be evaluated first:

```
(A(I)+1.0) .GT. B(I)*2.0
```

Some subexpressions might not be evaluated if the compiler can determine the result by testing other subexpressions in the logical expression. Consider the following expression:

```
A .AND. (F(X,Y) .GT. 2.0) .AND. B
```

If the compiler evaluates A first, and A is false, the compiler might determine that the expression is false and might not call the subprogram F(X,Y).

Summary of Operator Precedence

Defined Operations

When operators are defined for functions, the functions can then be referenced as defined operations.

The operators are defined by using a generic interface block specifying OPERATOR, followed by the defined operator (in parentheses).

A defined operation is not an intrinsic operation. However, you can use a defined operation to extend the meaning of an intrinsic operator.

For defined unary operations, the function must contain one argument. For defined binary operations, the function must contain two arguments.

Interpretation of the operation is provided by the function that defines the operation.

A Standard Fortran defined operator can contain up to 31 letters, and is enclosed in periods (.). Its name cannot be the same name as any of the following:

- The intrinsic operators (.NOT., .AND., .OR., .XOR., .EQV., .NEQV., .EQ., .NE., .GT., .GE., .LT., and .LE.)
- The logical literal constants (.TRUE. or .FALSE.)

An intrinsic operator can be followed by a defined unary operator.

The result of a defined operation can have any type. The type of the result (and its value) must be specified by the defining function.

Examples

The following examples show expressions containing defined operators:

```
.COMPLEMENT. A
X .PLUS. Y .PLUS. Z
M * .MINUS. N
```

	Defined Binary Operators	Lowest

Constant and Specification Expressions

A constant expression is an expression that is evaluated when a program is compiled. It can be used as a kind type parameter, a named constant, or to specify an initial value for an entity.

A specification expression is a scalar, integer expression that is restricted specifications such as length type parameters and array bounds.

Constant and specification expressions can appear in specification statements, with some restrictions.

Constant Expressions

A constant expression is an expression that you can use as a kind type parameter, a named constant, or to specify an initial value for an entity. It is evaluated when a program is compiled.

In a constant expression, each operation is intrinsic and each primary is one of the following:

- A constant or subobject of a constant
- A specification inquiry where each designator or function argument is one of the following:
  - A constant expression
  - A variable whose properties inquired about are not assumed, deferred, or defined by an expression that is not a constant expression
- A reference to the transformational function IEEE_SELECTED_REAL_KIND from the intrinsic module IEEE_ARITHMETIC, where each argument is a constant expression
- A kind type parameter of the derived type being defined
- A DO variable within an array constructor where each scalar integer expression of the corresponding DO loop is an constant expression
- Another constant expression enclosed in parentheses, where each subscript, section subscript, substring starting and ending point, and type parameter value is a constant expression

If a constant expression invokes an inquiry function for a type parameter or an array bound of an object, the type parameter or array bound must be specified in a prior specification statement (or to the left of the inquiry function in the same statement). The previous specification cannot be in the same entity declaration.

If a reference to a generic entity is included in a constant expression that is in the specification part of a module or submodule, that generic entity shall have no specific procedures defined subsequent to the constant expression in the module or submodule.

Examples

Valid constant Expressions

`-1 + 3`	
`SIZE(B)`	! B is a named constant
`7_2`	
`INT(J, 4)`	! J is a named constant
`SELECTED_INT_KIND (2)`	

Invalid constant Expressions

`SUM(A)`	Not an allowed function.
`A/4.1 - K**1.2`	Exponential does not have integer power (A and K are named constants).
`HUGE(4.0)`	Argument is not an integer.

Specification Expressions

A specification expression is a restricted scalar integer expression that you can use in specifications such as length type parameters and array bounds. Unless a specification expression is in an interface body, the specification part of a subprogram or BLOCK construct, a derived type definition, or the declaration type spec of a FUNCTION statement, it must be a constant expression.

In a restricted expression, each operation is intrinsic or defined by a specification function and each primary is one of the following:

- A constant or subobject of a constant
- An object designator with a base object that is one of the following:
  - A dummy argument that does not have the OPTIONAL or INTENT (OUT) attribute
  - In a common block
  - Made accessible by use or host association
  - A local variable of the procedure containing the BLOCK construct in which the restricted expression appears
  - A local variable of an outer BLOCK construct containing the BLOCK construct in which the restricted expression appears
  - An array constructor where each element and each scalar integer expression of each DO loop is a restricted expression
- A structure constructor whose components are restricted expression
- A specification inquiry where each designator or function argument is a restricted expression or a variable whose properties inquired about are not one of the following:
  - Dependent on the upper bound of the last dimension of an assumed-size array
  - Deferred
  - Defined by an expression that is not a restricted expression

- A specification inquiry that is a constant expression
- A reference to the PRESENT intrinsic function
- A reference to any other intrinsic function where each argument is a restricted expression
- A reference to an intrinsic transformational function from the intrinsic module ISO_C_BINDING where each argument is a restricted expression
- A reference to a specification function where each argument is a restricted expression
- A type parameter of the derived type being defined
- A DO variable within an array constructor, where each scalar integer expression of the corresponding implied-DO is a restricted expression
- A restricted expression enclosed in parentheses, where each subscript, section subscript, substring starting and ending point, and type parameter value is a restricted expression, and where any final subroutine that is invoked is pure

A specification inquiry is a reference to one of the following:

- An intrinsic inquiry function other than PRESENT
- A type parameter inquiry
- An intrinsic inquiry function from the modules IEEE_ARITHMETIC or IEEE_EXCEPTIONS
- The function C_SIZEOF from the intrinsic module ISO_C_BINDING
- The COMPILER_VERSION or COMPILER_OPTIONS inquiry function from the intrinsic module ISO_FORTRAN_ENV

Specification functions can be used in specification expressions to determine the attributes of data objects.

A function is a specification function if it is a pure function, does not have a dummy procedure argument, and is *not* one of the following:

- An standard intrinsic function
- An internal function
- A statement function
- A function with a dummy procedure argument

Evaluation of a specification expression must not directly or indirectly cause invocation of a procedure defined by the subprogram in which it appears.

NOTE
The requirement that specification functions be pure ensures that they cannot have side effects that could affect other objects being declared in the same specification.

The restriction that specification functions cannot be internal ensures that they cannot use host association to inquire about other objects being declared in the same specification. The restriction against recursion prevents the creation of a new instance of a procedure during construction of that procedure.

A variable in a specification expression must have its type and type parameters (if any) specified in one of the following ways:

- By a previous declaration in the same scoping unit
- By the implicit typing rules currently in effect for the scoping unit
- By host or use association

If a variable in a specification expression is typed by the implicit typing rules, its appearance in any subsequent type declaration statement must confirm the implied type and type parameters.

If a specification expression includes a specification inquiry that depends on a type parameter or an array bound or cobound of an entity specified in the same specification statement, the type parameter or array bound or cobound must be specified in a previous specification statement (or to the left of the inquiry function in the same statement). The previous specification cannot be in the same entity declaration. If a specification expression includes a reference to the value of an element of an array specified in the same specification statement, the array must be completely specified in previous declarations.

In the specification part of a module or submodule, if a specification expression includes a reference to a generic entity, that generic entity must have no specific procedures defined in the module or submodule subsequent to the specification expression.

In a specification expression, the number of arguments for a function reference is limited to 255.

Examples

The following shows valid specification expressions:

```
POPCNT(I) + J          ! I and J are scalar integer variables
UBOUND(ARRAY_B,20)  ! ARRAY_B is an assumed-shape dummy array
```

Assignments

An assignment causes variables to be defined or redefined.

Assignment is specified by the following:

- An intrinsic assignment statement

  This lets you assign a value to a nonpointer variable.
- A defined assignment statement

  This lets you specify an assignment operation.
- pointer assignment

  This lets you associate a pointer with a target.
- masked array assignment

  This kind of assignment is denoted by a WHERE construct or statement. It lets you perform an array operation on selected elements in an array.
- element array assignment

  This kind of assignment is denoted by a FORALL construct or statement. It is a generalization of masked array assignment. It allows more general array shapes to be assigned, especially if it is used in construct form.

Note that the ASSIGN statement assigns a label to an integer variable. It is discussed elsewhere.

Intrinsic Assignment Statements

Intrinsic assignment is used to assign a value to a nonpointer variable. In the case of pointers, intrinsic assignment is used to assign a value to the target associated with the pointer variable. The value assigned to the variable (or target) is determined by evaluation of the expression to the right of the equal sign.

An intrinsic assignment statement takes the following form:

variable = expression

variable	Is the name of a scalar or array of intrinsic or derived type (with no defined assignment). The array cannot be an assumed-size array, and neither the scalar nor the array can be declared with the PARAMETER or INTENT(IN) attribute.

expression	Is of intrinsic type or the same derived type as *variable*. Its shape must conform with *variable*. If necessary, it is converted to the same type and kind as *variable*.

Description

Before a value is assigned to the variable, the expression part of the assignment statement and any expressions within the variable are evaluated. No definition of expressions in the variable can affect or be affected by the evaluation of the expression part of the assignment statement.

> **NOTE**
> When the run-time system assigns a value to a scalar integer or character variable and the variable is shorter than the value being assigned, the assigned value may be truncated and significant bits (or characters) lost. This truncation can occur without warning, and can cause the run-time system to pass incorrect information back to the program.

The following rules apply to intrinsic assignment statements:

- The variable and expression must be conformable unless the variable is an allocatable array that has the same rank as the expression, and is neither a coarray nor a coindexed object.
- If the expression is an array, then the variable must also be an array.
- If the variable is polymorphic, it must be allocatable and it must not be a coarray. The polymorphic variable must be type compatible with the expression and of the same rank. If it is allocated but the dynamic type differs from that of the expression, it is deallocated. If it is not allocated or becomes deallocated, it is allocated with the dynamic type of the expression.
- If the variable is a pointer, it must be associated with a definable target. The shape of the target and expression must conform and their type and kind parameters must match.
- If the variable is of type character, the expression must have the same kind type parameter.
- If the variable is of derived type:
  - Each kind type parameter of the variable must have the same value as the corresponding kind type parameter of the expression.
  - Each length type parameter of the variable must have the same value as the corresponding type parameter of the expression unless the variable is an allocatable array and its corresponding type parameter is deferred.
- If the variable is a coindexed object, each deferred-length type parameter must have the same value as the corresponding type parameter of the expression. Also, the variable must not be polymorphic, and it must not have an allocatable ultimate component.

The following sections discuss numeric, logical, character, derived- type, and array intrinsic assignment.

Examples of Intrinsic Assignment to Polymorphic Variables

Numeric Assignment Statements

For numeric assignment statements, the variable and expression must be numeric type. The expression may also be of logical type.

The expression must yield a value that conforms to the range requirements of the variable. For example, a real expression that produces a value greater than 32767 is invalid if the entity on the left of the equal sign is an INTEGER(2) variable.

Significance can be lost if an INTEGER(4) value, which can exactly represent values of approximately the range -2*10**9 to +2*10**9, is converted to REAL(4) (including the real part of a complex constant), which is accurate to only about seven digits.

If the variable has the same data type as that of the expression on the right, the statement assigns the value directly. If the data types are different, the value of the expression is converted to the data type of the variable before it is assigned.

The following table summarizes the data conversion rules for numeric assignment statements.

Conversion Rules for Numeric Assignment Statements

Scalar Memory Reference (V)	Expression (E)	
	Integer or Real	**Complex**
Integer	V=INT(E)	V=INT(REAL(E)) Imaginary part of E is not used.
REAL (KIND=4)	V=REAL(E)	V=REAL(REAL(E)) Imaginary part of E is not used.
REAL (KIND=8)	V=DBLE(E)	V=DBLE(REAL(E)) Imaginary part of E is not used.
REAL (KIND=16)	V=QEXT(E)	V=QEXT(REAL(E)) Imaginary part of E is not used.
COMPLEX (KIND=4)	V=CMPLX(REAL(E), 0.0)	V=CMPLX(REAL(REAL(E)), REAL(AIMAG(E)))
COMPLEX (KIND=8)	V=CMPLX(DBLE(E), 0.0)	V=CMPLX(DBLE(REAL(E)), DBLE(AIMAG(E)))
COMPLEX (KIND=16)	V=CMPLX(QEXT(E), 0.0)	V=CMPLX(QEXT(REAL(E)), QEXT(AIMAG(E)))

If the expression (E) is of type logical, it is first converted to type integer as follows:

- If E evaluates to .TRUE. the result is -1 or 1 depending on the setting of the compiler option `fpscomp logicals`
- Otherwise the result is 0

The result of this conversion is then interpreted according to the above table.

Examples

Valid Numeric Assignment Statements

```
BETA = -1./(2.*X)+A*A /(4.*(X*X))

PI = 3.14159

SUM = SUM + 1.

ARRAY_A = ARRAY_B + ARRAY_C + SCALAR_I        ! Valid if all arrays conform in shape
```

Invalid Numeric Assignment Statements

```
3.14 = A - B                                  Entity on the left must be a variable.

ICOUNT = A//B(3:7)                            Implicitly typed data types do not match.
```

SCALAR_I = ARRAY_A(:)	Shapes do not match.

AIMAG

Logical Assignment Statements

For logical assignment statements, the variable must be of logical type and the expression can be of logical or numeric type.

If the expression is of numeric type, it is converted to integer if necessary, then the value is interpreted as .TRUE. or .FALSE. according to the setting of the compiler option `fpscomp logicals`.

Examples

The following examples demonstrate valid logical assignment statements:

```
PAGEND = .FALSE.
PRNTOK = LINE .LE. 132 .AND. .NOT. PAGEND
ABIG = A.GT.B .AND. A.GT.C .AND. A.GT.D
LOGICAL_VAR = 123 ! Assigns .TRUE. to LOGICAL_VAR
```

Character Assignment Statements

For character assignment statements, the variable and expression must be of character type and have the same kind parameter.

The variable and expression can have different lengths. If the length of the expression is greater than the length of the variable, the character expression is truncated on the right. If the length of the expression is less than the length of the variable, the character expression is filled on the right with blank characters.

If you assign a value to a character substring, you do not affect character positions in any part of the character scalar variable not included in the substring. If a character position outside of the substring has a value previously assigned, it remains unchanged. If the character position is undefined, it remains undefined.

Examples

Valid Character Assignment Statements. (All variables are of type character.)

```
FILE = 'PROG2'

REVOL(1) = 'MAR'//'CIA'

LOCA(3:8) = 'PLANT5'

TEXT(I,J+1)(2:N-1) = NAME//X
```

Invalid Character Assignment Statements

`'ABC' = CHARS`	Left element must be a character variable, array element, or substring reference.
`CHARS = 25`	Expression does not have a character data type.

`STRING=5HBEGIN`	Expression does not have a character data type. (Hollerith constants are numeric, not character.)

Derived-Type Assignment Statements

In derived-type assignment statements, the variable and expression must be of the same derived type. There must be no accessible interface block with defined assignment for objects of this derived type.

The derived-type assignment is performed as if each component of the expression is assigned to the corresponding component of the variable. Pointer assignment is performed for pointer components, and intrinsic assignment is performed for nonpointer components.

Examples

The following example shows derived-type assignment:

```
TYPE DATE
  LOGICAL(1) DAY, MONTH
  INTEGER(2) YEAR
END TYPE DATE

TYPE(DATE) TODAY, THIS_WEEK(7)
TYPE APPOINTMENT
...
  TYPE(DATE) APP_DATE
END TYPE

TYPE(APPOINTMENT) MEETING

DO I = 1,7
  CALL GET_DATE(TODAY)
  THIS_WEEK(I) = TODAY
END DO
MEETING%APP_DATE = TODAY
```

See Also

Derived types
Pointer assignments

Array Assignment Statements

Array assignment is permitted when the array expression on the right has the same shape as the array variable on the left, or the expression on the right is a scalar.

If the expression is a scalar, and the variable is an array, the scalar value is assigned to every element of the array.

If the expression is an array, the variable must also be an array. The array element values of the expression are assigned (element by element) to corresponding elements of the array variable.

A *many-one array section* is a vector-valued subscript that has two or more elements with the same value. In intrinsic assignment, the variable cannot be a many-one array section because the result of the assignment is undefined.

Examples

In the following example, X and Y are arrays of the same shape:

```
  X = Y
```

The corresponding elements of Y are assigned to those of X element by element; the first element of Y is assigned to the first element of X, and so forth. The processor can perform the element-by-element assignment in any order.

The following example shows a scalar assigned to an array:

```
B(C+1:N, C) = 0
```

This sets the elements B (C+1,C), B (C+2,C),...B (N,C) to zero.

The following example causes the values of the elements of array A to be reversed:

```
REAL A(20)
...
A(1:20) = A(20:1:-1)
```

Examples of Intrinsic Assignment to Polymorphic Variables

Intrinsic assignment to an allocatable polymorphic variable is allowed. The variable must be type compatible with the expression and of the same rank. If it is allocated but the dynamic type differs from that of the expression, it is deallocated. If it is not allocated or becomes deallocated, it is allocated with the dynamic type of the expression.

Syntax:

assignment-stmt is *variable = expr*

variable is an allocatable polymorphic and *expr* is not necessarily an allocatable, but *variable* and *expr* must be type compatible.

A polymorphic entity that is not an unlimited polymorphic entity is type compatible with entities of the same declared type or any of its extensions. Even though an unlimited polymorphic entity is not considered to have a declared type, it is type compatible with all entities.

variable and *expr* must be of the same rank.

If *expr* is a scalar and *variable* is allocated, then *expr* is treated as an array with the same bounds as *variable*, so the bounds of *variable* would remain unchanged. It is an error if *variable* is unallocated when *expr* is a scalar.

In the examples below, we have the following types:

```
Type type1
End type

Type type2
End type

Type, extends(type1) :: type3
End type
```

Example of same type and same size:

If *variable* is the same type and size as *expr* then just do the assignment.

```
Class(type1), allocatable :: var
Class(type1), allocatable :: expr
Allocate(expr, source=type1())
Allocate(var, source=type1())
var = expr             ! No deallocation of var, simple assignment
```

Example of same type and different size:

If *variable* is the same type as *expr* but their sizes are not the same then deallocate `var`, reallocate it, and then do the assignment.

```
Class(type1), allocatable :: var(:)
Class(type1), allocatable :: expr(:)
Allocate(var(5), source=type1())
Allocate(expr(6), source=type1())
var = expr              ! var deallocated and then
                        ! allocated to the size of expr - then
                        ! the usual assignment is performed
```

Example of different types or shape and same size:

If *variable* and *expr* are of different types or shapes but of the same size, then do the assignment and update the type/bounds of `var` to be same as that of `expr`, only if type1 and type3 are type compatible.

```
Class(type1), allocatable :: var(:,:)
Class(type1), allocatable :: expr(:,:)
Allocate(var(2,3), source=type1())
Allocate(expr(3,2), source=type3())
var = expr              ! No deallocation
                        ! simple assignment with var's
                        ! bounds updated
```

Example of different types or shape and different size:

If *variable* and *expr* are of different types or shapes and of different sizes, then deallocate `var` and allocate it with the same type and shape as `expr`, only if type1 and type3 are type compatible.

```
Class(type1), allocatable :: var(:,:)
Class(type3), allocatable :: expr(:,:)
Allocate(var(2,4), source=type1())
Allocate(expr(3,3), source=type3())
var = expr              ! var deallocated and then
                        ! allocated to the size of expr and
                        ! then the usual assignment var
                        ! has dynamic type set to type3
```

Example of incompatible types on Left-Hand Side (LHS) and Right-Hand Side (RHS):

If LHS and RHS are type incompatible then you get an error.

```
Class(type1), allocatable :: var
Class(type2), allocatable :: expr
Allocate(var,source=type1())
Allocate(expr,source=type2())
var = expr              ! This is an error
```

Example of unallocated allocatable polymorphic on the LHS:

If `var` is unallocated then `expr` must be a scalar or it is a shape mismatch error.

```
Class(*), allocatable :: var(:)
var = 5                 ! This is an error
```

Otherwise, allocate `var` with same dynamic type, shape, and size as `expr`.

```
Class(*), allocatable :: var
var = 5                 ! This is valid
```

Example of unlimited polymorphic on the LHS:

Unlimited polymorphic allocatable on the LHS is type compatible with any type. If `var` is of a different size than `expr`, `var` is deallocated and then allocated with the type and shape of `expr`.

```
Class(*), allocatable :: var
Class(type2), allocatable :: expr
Allocate(var, source=type1())
Allocate(expr, source=type2())
var = expr              ! var is an unlimited polymorphic
                        ! so it is type compatible with
                        ! any type expr
```

Defined Assignment Statements

Defined assignment specifies an assignment operation. It is defined by a subroutine subprogram containing a generic interface block that specifies ASSIGNMENT(=). The subroutine is specified in a SUBROUTINE or ENTRY statement that has two nonoptional dummy arguments.

Defined elemental assignment is indicated by specifying ELEMENTAL in the SUBROUTINE statement.

The dummy arguments represent the variable and expression, in that order. The rank (and shape, if either or both are arrays), type, and kind parameters of the variable and expression in the assignment statement must match those of the corresponding dummy arguments.

The dummy arguments must not both be numeric, or of type logical or character with the same kind parameter.

If the variable in an elemental assignment is an array, the defined assignment is performed element-by-element, in any order, on corresponding elements of the variable and expression. If the expression is scalar, it is treated as if it were an array of the same shape as the variable with every element of the array equal to the scalar value of the expression.

Pointer Assignments

In ordinary assignment involving pointers, the pointer is an alias for its target. In pointer assignment, the pointer is associated with a target. If the target is undefined or disassociated, the pointer acquires the same status as the target. Pointer assignment has the following form:

pointer-object [(*s-spec*)] => *target*

pointer-object	Is a variable name or structure component declared with the POINTER attribute.
s-spec	Is a shape specification consisting of bounds information in the form "[*lower-bound*]:" or "[*lower-bound*] :*upper-bound*".
target	Is a variable or expression. Its type and kind parameters, and rank must be the same as *pointer-object* unless bounds remapping is specified. It cannot be an array section with a vector subscript.

Description

If the target is a variable, it must have the POINTER or TARGET attribute, or be a subobject whose parent object has the TARGET attribute.

If the target is an expression, the result must be a pointer.

If the target is not a pointer (it has the TARGET attribute), the pointer object is associated with the target.

If the target is a pointer (it has the POINTER attribute), its status determines the status of the pointer object, as follows:

- If the pointer is associated, the pointer object is associated with the same object as the target
- If the pointer is disassociated, the pointer object becomes disassociated
- If the pointer is undefined, the pointer object becomes undefined

A pointer must not be referenced or defined unless it is associated with a target that can be referenced or defined.

When pointer assignment occurs, any previous association between the pointer object and a target is terminated.

Pointers can also be assigned for a pointer structure component by execution of a derived-type intrinsic assignment statement or a defined assignment statement.

Pointers can also become associated by using the ALLOCATE statement to allocate the pointer.

Pointers can become disassociated by deallocation, nullification of the pointer (using the DEALLOCATE or NULLIFY statements), or by reference to the NULL intrinsic function.

Pointer assignment for arrays allows lower bounds to be specified. The specified lower bounds can be any scalar integer expressions.

Remapping of the elements of a rank-one array is permitted. The mapping is in array-element order and the target array must be large enough. The specified bounds may be any scalar integer expressions.

Examples

The following are examples of pointer assignments:

```
HOUR => MINUTES(1:60)            ! target is an array
M_YEAR => MY_CAR%YEAR          ! target is a structure component
NEW_ROW%RIGHT => CURRENT_ROW     ! pointer object is a structure component
PTR => M                       ! target is a variable
POINTER_C => NULL ()             ! reference to NULL intrinsic
```

The following example shows a target as a pointer:

```
INTEGER, POINTER :: P, N
INTEGER, TARGET :: M
INTEGER S
M = 14
N => M                          ! N is associated with M
P => N                          ! P is associated with M through N
S = P + 5
```

The value assigned to S is 19 (14 + 5).

You can use the intrinsic function ASSOCIATED to find out if a pointer is associated with a target or if two pointers are associated with the same target. For example:

```
REAL C (:), D(:), E(5)
POINTER C, D
TARGET E
LOGICAL STATUS
! Pointer assignment.
C => E
! Pointer assignment.
D => E
! Returns TRUE; C is associated.
STATUS = ASSOCIATED (C)
! Returns TRUE; C is associated with E.
```

```
  STATUS = ASSOCIATED (C, E)
  ! Returns TRUE; C and D are associated with the
  ! same target.
  STATUS = ASSOCIATED (C, D)
```

The following example shows how to specify lower bounds on a pointer:

```
REAL, TARGET :: A(4,4)
POINTER P
P (0:,0:) => A            ! LBOUND (P) == [0,0]
                          ! UBOUND (P) == [3,3]
```

The following example shows pointer remapping of the elements of a rank-one array:

```
REAL, TARGET :: V(100)
POINTER P
INTEGER N
P(1:N,1:2*N) => V(1:2*N*N)
```

Specification Statements

A *specification statement* is a nonexecutable statement that declares the attributes of data objects. In Standard Fortran, many of the attributes that can be defined in specification statements can also be optionally specified in type declaration statements.

The following are specification statements:

- Type Declarations

  Explicitly specify the properties (for example: data type, rank, and extent) for data objects or functions.
- ALLOCATABLE attribute and statement

  Specifies that an array is an allocatable array with a deferred shape. The shape of an allocatable array is determined when an ALLOCATE statement is executed, dynamically allocating space for the array.
- ASYNCHRONOUS attribute and statement

  Specifies that a variable can be used for asynchronous input and output.
- AUTOMATIC and STATIC attributes and statements

  Control the storage allocation of variables in subprograms.
- BIND attribute and statement

  Specifies that an object is interoperable with C and has external linkage.
- CODIMENSION attribute and statement

  Specifies that an entity is a coarray.
- COMMON statement

Defines one or more contiguous areas, or blocks, of physical storage (called common blocks) that can be accessed by any of the scoping units in an executable program. COMMON statements also define the order in which variables and arrays are stored in each common block, which can prevent misaligned data items.

- CONTIGUOUS attribute and statement

  Specifies that the target of a pointer or an assumed-sized array is contiguous.
- DATA statement

  Assigns initial values to variables before program execution.
- DIMENSION attribute and statement

  Specifies that an object is an array, and defines the shape of the array.
- EQUIVALENCE statement

  Specifies that a storage area is shared by two or more objects in a program unit. This causes total or partial storage association of the objects that share the storage area.
- EXTERNAL attribute and statement

  Allows an external or dummy procedure to be used as an actual argument.
- IMPLICIT statement

  Overrides the default implicit typing rules for names.
- INTENT attribute and statement

  Specifies the intended use of one or more dummy arguments.
- INTRINSIC attribute and statement

  Allows the specific name of an intrinsic procedure to be used as an actual argument. Certain specific function names cannot be used. For more information, see Intrinsic Functions Not Allowed as Actual Arguments.
- NAMELIST statement

  Associates a name with a list of variables. This group name can be referenced in some input/output operations.
- OPTIONAL attribute and statement

  Allows dummy arguments to be omitted in a procedure reference.
- PARAMETER attribute and statement

  Defines a named constant.
- POINTER attribute and statement

  Specifies that an object or a procedure is a pointer (a dynamic variable).
- PRIVATE and PUBLIC and attributes and statements

  Specifies the accessibility of entities in a module. (These attributes are also called accessibility attributes.)
- PROTECTED attribute and statement

  Specifies limitations on the use of module entities.
- SAVE attribute and statement

  Causes the values and definition of objects to be retained after execution of a RETURN or END statement in a subprogram.
- TARGET attribute and statement

  Specifies that an object can become the target of a pointer.
- VALUE attribute and statement

  Specifies a type of argument association for a dummy argument.
- VOLATILE attribute and statement

  Specifies that the value of an object is entirely unpredictable, based on information local to the current program unit.

Type Declarations

A type declaration is a nonexecutable statement specifying the data type of one or more variables. The declaration can be specified in an INTEGER, REAL, DOUBLE PRECISION, COMPLEX, DOUBLE COMPLEX, CHARACTER, LOGICAL, or TYPE statement. A type declaration statement may also specify attributes for the variables.

Declarations for Noncharacter Types

The following table shows the data types that can appear in noncharacter type declarations.

Noncharacter Data Types
BYTE[1]
LOGICAL[2]
LOGICAL([KIND=]1) (or LOGICAL*1)
LOGICAL([KIND=]2) (or LOGICAL*2)
LOGICAL([KIND=]4) (or LOGICAL*4)
LOGICAL([KIND=]8) (or LOGICAL*8)
INTEGER[3]
INTEGER([KIND=]1) (or INTEGER*1)
INTEGER([KIND=]2) (or INTEGER*2)
INTEGER([KIND=]4) (or INTEGER*4)
INTEGER([KIND=]8) (or INTEGER*8)
REAL[4]
REAL([KIND=]4) (or REAL*4)
DOUBLE PRECISION (REAL([KIND=]8) or REAL*8)
REAL([KIND=]16) (or REAL*16)
COMPLEX[5]
COMPLEX([KIND=]4) (or COMPLEX*8)
DOUBLE COMPLEX (COMPLEX([KIND=]8) or COMPLEX*16)
COMPLEX([KIND=]16) (or COMPLEX*32)

[1] Same as INTEGER(1).

[2] This is treated as default logical.

[3] This is treated as default integer.

[4] This is treated as default real.

Noncharacter Data Types

[5] This is treated as default complex.

In noncharacter type declarations, you can optionally specify the name of the data object or function as v*n, where *n* is the length (in bytes) of *v*. The length specified overrides the length implied by the data type.

The value for *n* must be a valid length for the type of *v*. The type specifiers BYTE, DOUBLE PRECISION, and DOUBLE COMPLEX have one valid length, so the *n* specifier is invalid for them.

For an array specification, the *n* must be placed immediately following the array name; for example, in an INTEGER declaration, IVEC*2(10) is an INTEGER(2) array of 10 elements.

Note that certain compiler options can affect the defaults for numeric and logical data types.

Examples

In a noncharacter type declaration, a subsequent kind parameter overrides any initial kind parameter. For example, consider the following statements:

```
INTEGER(KIND=2) I, J, K, M12*4, Q, IVEC*4(10)
REAL(KIND=8) WX1, WXZ, WX3*4, WX5, WX6*4
REAL(KIND=8) PI/3.14159E0/, E/2.72E0/, QARRAY(10)/5*0.0,5*1.0/
```

In the first statement, M12*4 and IVEC*4 override the KIND=2 specification. In the second statement, WX3*4 and WX6*4 override the KIND=8 specification. In the third statement, QARRAY is initialized with implicit conversion of the REAL(4) constants to a REAL(8) data type.

See Also

Type Declarations for details on the general form and rules for type declarations

Declarations for Character Types

A CHARACTER type specifier can be immediately followed by an optional KIND type parameter and the length of the character object or function. It takes one of the following forms:

Keyword Forms

CHARACTER ([LEN=] *len*)

CHARACTER [([LEN=] *len* [, [KIND=] *n*])]

CHARACTER [(KIND= *n* [, LEN= *len*])]

Obsolete Form

CHARACTER* *len*[,]

len

Is a length type parameter. It can have one of the following values:

- A scalar integer expression
- *
- :

The following rules also apply:

- In keyword forms

  The *len* is a specification expression, an asterisk (*), or a colon (:). If no length is specified, the default length is 1.

  If the length evaluates to a negative value, the length of the character entity is zero.
- In the obsolete form

The *len* is a specification expression or an asterisk enclosed in parentheses, or a scalar integer literal constant (with no kind parameter). The comma is permitted only if no double colon (::) appears in the type declaration statement.

This form can also (optionally) be specified following the name of the data object or function (*v***len*). In this case, the length specified overrides any length following the CHARACTER type specifier.

The largest valid value for *len* in both forms is 2**31-1 on IA-32 architecture; 2**63-1 on Intel® 64 architecture. Negative values are treated as zero.

n

Is a scalar integer constant expression specifying a valid kind parameter. Currently the only kind available is 1.

Description

An automatic object can appear in a character declaration. The object cannot be a dummy argument, and its length must be declared with a specification expression that is not a constant expression.

The length specified for a character-valued statement function or statement function dummy argument of type character must be an integer constant expression.

When an asterisk length specification *(*) is used for a function name or dummy argument, it assumes the length of the corresponding function reference or actual argument. Similarly, when an asterisk length specification is used for a named constant, the name assumes the length of the actual constant it represents. For example, STRING assumes a 9-byte length in the following statements:

```
CHARACTER*(*) STRING
PARAMETER (STRING = 'VALUE IS:')
```

A function name must not be declared with a * length unless it is of type CHARACTER and is the name of the result of an external function or the name of a dummy function.

A function name declared with a * length must not be an array, a pointer, recursive, elemental, or pure.

If the CHARACTER type declaration statement specifies a colon (:) length, the length type parameter is a deferred type parameter. An entity or component with a deferred type parameter must specify the ALLOCATABLE or POINTER attribute. A deferred type parameter is a length type parameter whose value can change during execution of the program.

The obsolete form is an obsolescent feature in the Fortran standard.

Examples

In the following example, the character string last_name is given a length of 20:

```
CHARACTER (LEN=20) last_name
```

In the following example, stri is given a length of 12, while the other two variables retain a length of 8.

```
CHARACTER *8 strg, strh, stri*12
```

In the following example, a dummy argument strh will assume the length of the associated actual argument, while the other two variables retain a length of 8:

```
CHARACTER *8 strg, strh(*), stri
```

The following examples show ways to specify strings of known length:

```
CHARACTER*32 string1
CHARACTER string2*32
```

The following examples show ways to specify strings of unknown length:

```
CHARACTER string3*(*)
CHARACTER*(*) string4
```

The following example declares an array NAMES containing 100 32-character elements, an array SOCSEC containing 100 9-character elements, and a variable NAMETY that is 10 characters long and has an initial value of 'ABCDEFGHIJ'.

```
CHARACTER*32 NAMES(100),SOCSEC(100)*9,NAMETY*10 /'ABCDEFGHIJ'/
```

The following example includes a CHARACTER statement declaring two 8-character variables, LAST and FIRST.

```
INTEGER, PARAMETER :: LENGTH=4
CHARACTER*(4+LENGTH) LAST, FIRST
```

The following example shows a CHARACTER statement declaring an array LETTER containing 26 one-character elements. It also declares a dummy argument BUBBLE that has a passed length defined by the calling program.

```
CHARACTER LETTER(26), BUBBLE*(*)
```

In the following example, NAME2 is an automatic object:

```
SUBROUTINE AUTO_NAME(NAME1)
  CHARACTER(LEN = *) NAME1
  CHARACTER(LEN = LEN(NAME1)) NAME2
```

The following example shows the handling of a deferred-length CHARACTER variables:

```
CHARACTER(:), ALLOCATABLE :: namea
namea = 'XYZ'                   ! Allocates namea as length 3 with value 'XYZ'
DEALLOCATE (namea)
ALLOCATE (CHARACTER(10)::namea) ! Allocates namea as length 10, no value
namea = 'ABCDEF'                ! Reallocates namea to length 6 with value 'ABCDEF'
```

Assumed-Length Character Arguments for details on asterisk length specifications
Type Declarations for details on the general form and rules for type declaration statements

Declarations for Derived Types

A derived-type declaration specifies the properties of objects and functions of derived (user-defined) type.

The derived type must be defined before you can specify objects of that type in a TYPE type declaration.

An object of derived type must not have the PUBLIC attribute if its type is PRIVATE.

A structure constructor specifies values for derived-type objects.

Examples

The following are examples of derived-type declarations:

```
TYPE(EMPLOYEE) CONTRACT
...
TYPE(SETS), DIMENSION(:,:), ALLOCATABLE :: SUBSET_1
```

The following example shows a public type with private components:

```
TYPE LIST_ITEMS
  PRIVATE
  ...
  TYPE(LIST_ITEMS), POINTER :: NEXT, PREVIOUS
END TYPE LIST_ITEMS
```

Type Declarations for details on the general form and rules for type declarations

Declarations for Arrays

An array declaration (or array declarator) declares the shape of an array. It takes the following form:

(*a-spec*)

a-spec — Is one of the following array specifications:

- Explicit-shape
- Assumed-shape
- Assumed-size
- Deferred-shape
- Assumed-rank
- Implied-shape

The array specification can be appended to the name of the array when the array is declared.

Examples

The following examples show array declarations:

```
SUBROUTINE SUB(N, C, D, Z)
  REAL, DIMENSION(N, 15) :: IARRY       ! An explicit-shape array
  REAL C(:), D(0:)                      ! An assumed-shape array
  REAL, POINTER :: B(:,:)               ! A deferred-shape array pointer
  REAL, ALLOCATABLE, DIMENSION(:) :: K  ! A deferred-shape allocatable array
  REAL :: Z(N,*)                        ! An assumed-size array
  INTEGER, PARAMETER :: R(*) = [1,2,3]  ! An implied-shape constant array
```

See Also

Type Declarations for details on the general form and rules for type declaration statements

Explicit-Shape Specifications

An *explicit-shape array* is declared with explicit values for the bounds in each dimension of the array. An explicit-shape specification takes the following form:

([*dl*:] *du*[, [*dl*:] *du*] ...)

dl — Is a specification expression indicating the lower bound of the dimension. The expression can have a positive, negative, or zero value. If necessary, the value is converted to integer type.

If the lower bound is not specified, it is assumed to be 1.

du	Is a specification expression indicating the upper bound of the dimension. The expression can have a positive, negative, or zero value. If necessary, the value is converted to integer type.

The bounds can be specified as constant or nonconstant expressions, as follows:

- If the bounds are constant expressions, the subscript range of the array in a dimension is the set of integer values between and including the lower and upper bounds. If the lower bound is greater than the upper bound, the range is empty, the extent in that dimension is zero, and the array has a size of zero.
- If the bounds are nonconstant expressions, the array must be declared in a procedure. The bounds can have different values each time the procedure is executed, since they are determined when the procedure is entered.

  The bounds are not affected by any redefinition or undefinition of the variables in the specification expression that occurs while the procedure is executing.

  The following explicit-shape arrays can specify nonconstant bounds:

  - An automatic array (the array is a local variable)
  - An adjustable array (the array is a dummy argument to a subprogram)

The following are examples of explicit-shape specifications:

```
INTEGER I(3:8, -2:5)          ! Rank-two array; range of dimension one is
...                           ! 3 to 8, range of dimension two is -2 to 5
SUBROUTINE SUB(A, B, C)
  INTEGER :: B, C
  REAL, DIMENSION(B:C) :: A   ! Rank-one array; range is B to C
```

Consider the following:

```
 INTEGER M(10, 10, 10)
 INTEGER K(-3:6, 4:13, 0:9)
```

M and K are both explicit-shape arrays with a rank of 3, a size of 1000, and the same shape (10,10,10). Array M uses the default lower bound of 1 for each of its dimensions. So, when it is declared only the upper bound needs to be specified. Each of the dimensions of array K has a lower bound other than the default, and the lower bounds as well as the upper bounds are declared.

Automatic Arrays

An *automatic array* is an explicit-shape array that is a local variable. Automatic arrays are only allowed in function and subroutine subprograms, and are declared in the specification part of the subprogram. At least one bound of an automatic array must be a nonconstant specification expression. The bounds are determined when the subprogram is called.

The following example shows automatic arrays:

```
SUBROUTINE SUB1 (A, B)
  INTEGER A, B, LOWER
  COMMON /BOUND/ LOWER
  ...
  INTEGER AUTO_ARRAY1(B)
  ...
  INTEGER AUTO_ARRAY2(LOWER:B)
  ...
  INTEGER AUTO_ARRAY3(20, B*A/2)
END SUBROUTINE
```

Consider the following:

```
 SUBROUTINE EXAMPLE (N, R1, R2)
   DIMENSION A (N, 5), B(10*N)
   ...
   N = IFIX(R1) + IFIX(R2)
```

When the subroutine is called, the arrays A and B are dimensioned on entry into the subroutine with the value of the passed variable N. Later changes to the value of N have no effect on the dimensions of array A or B.

Adjustable Arrays

An *adjustable array* is an explicit-shape array that is a dummy argument to a subprogram. At least one bound of an adjustable array must be a nonconstant specification expression. The bounds are determined when the subprogram is called.

The array specification can contain integer variables that are either dummy arguments or variables in a common block.

When the subprogram is entered, each dummy argument specified in the bounds must be associated with an actual argument. If the specification includes a variable in a common block, the variable must have a defined value. The array specification is evaluated using the values of the actual arguments, as well as any constants or common block variables that appear in the specification.

The size of the adjustable array must be less than or equal to the size of the array that is its corresponding actual argument.

To avoid possible errors in subscript evaluation, make sure that the bounds expressions used to declare multidimensional adjustable arrays match the bounds as declared by the caller.

In the following example, the function computes the sum of the elements of a rank-two array. Notice how the dummy arguments M and N control the iteration:

```
  FUNCTION THE_SUM(A, M, N)
    DIMENSION A(M, N)
    SUMX = 0.0
    DO J = 1, N
      DO I = 1, M
        SUMX = SUMX + A(I, J)
      END DO
    END DO
    THE_SUM = SUMX
  END FUNCTION
```

The following are examples of calls on THE_SUM:

```
DIMENSION A1(10,35), A2(3,56)
SUM1 = THE_SUM(A1,10,35)
SUM2 = THE_SUM(A2,3,56)
```

The following example shows how the array bounds determined when the procedure is entered do not change during execution:

```
DIMENSION ARRAY(9,5)
L = 9
M = 5
CALL SUB(ARRAY,L,M)
END

SUBROUTINE SUB(X,I,J)
  DIMENSION X(-I/2:I/2,J)
  X(I/2,J) = 999
  J = 1
  I = 2
END
```

The assignments to I and J do not affect the declaration of adjustable array X as X(-4:4,5) on entry to subroutine SUB.

See Also

Specification expressions

Assumed-Shape Specifications

An *assumed-shape array* is a dummy argument array that assumes the shape of its associated actual argument array. An assumed-shape specification takes the following form:

([*dl*]:[, [*dl*]:] ...)

dl	Is a specification expression indicating the lower bound of the dimension. The expression can have a positive, negative, or zero value. If necessary, the value is converted to integer type. If the lower bound is not specified, it is assumed to be 1.

The rank of the array is the number of colons (:) specified.

The value of the upper bound is the extent of the corresponding dimension of the associated actual argument array + *lower-bound* - 1.

Examples

The following is an example of an assumed-shape specification:

```
INTERFACE
  SUBROUTINE SUB(M)
    INTEGER M(:, 1:, 5:)
  END SUBROUTINE
END INTERFACE
INTEGER L(20, 5:25, 10)

CALL SUB(L)
SUBROUTINE SUB(M)
  INTEGER M(:, 1:, 5:)
END SUBROUTINE
```

Array M has the same extents as array L, but array M has bounds (1:20, 1:21, 5:14).

Note that an explicit interface is *required* when calling a routine that expects an assumed-shape or pointer array.

Consider the following:

```
SUBROUTINE ASSUMED(A)
  REAL A(:, :, :)
```

Array A has rank 3, indicated by the three colons (:) separated by commas (,). However, the extent of each dimension is unspecified. When the subroutine is called, A takes its shape from the array passed to it. For example, consider the following:

```
REAL X (4, 7, 9)
...
CALL ASSUMED(X)
```

This gives A the dimensions (4, 7, 9). The actual array and the assumed-shape array must have the same rank.

Consider the following:

```
SUBROUTINE ASSUMED(A)
  REAL A(3:, 0:, -2:)
...
```

If the subroutine is called with the same actual array X(4, 7, 9), as in the previous example, the lower and upper bounds of A would be:

```
A(3:6, 0:6, -2:6)
```

Assumed-Size Specifications

An *assumed-size array* is a dummy argument array that assumes the size (only) of its associated actual argument array, or the associate name of a RANK (*) block in a SELECT RANK construct. The rank and extents can differ for the actual and dummy arrays. An assumed-size specification takes the following form:

([*expli-shape-spec*,] [*expli-shape-spec*,] ... [*dl*:] *)

expli-shape-spec	Is an explicit-shape specification.
dl	Is a specification expression indicating the lower bound of the dimension. The expression can have a positive, negative, or zero value. If necessary, the value is converted to integer type. If the lower bound is not specified, it is assumed to be 1.
*	Is the upper bound of the last dimension.

The rank of the array is the number of explicit-shape specifications plus 1.

The size of the array is assumed from the actual argument associated with the assumed-size dummy array as follows:

- If the actual argument is an array of type other than default character, the size of the dummy array is the size of the actual array.
- If the actual argument is an array element of type other than default character, the size of the dummy array is `a + 1 - s`, where *s* is the subscript order value and *a* is the size of the actual array.
- If the actual argument is a default character array, array element, or array element substring, and it begins at character storage unit *b* of an array with *n* character storage units, the size of the dummy array is as follows:

```
MAX(INT((n + 1 - b)/y), 0)
```

  The *y* is the length of an element of the dummy array.

An assumed-size array can only be used as a whole array reference in the following cases:

- When it is an actual argument in a procedure reference that does not require the shape
- In the intrinsic function LBOUND

Because the actual size of an assumed-size array is unknown, an assumed-size array cannot be used as any of the following in an I/O statement:

- An array name in the I/O list
- A unit identifier for an internal file
- A run-time format specifier

Examples

The following is an example of an assumed-size specification:

```
SUBROUTINE SUB(A, N)
  REAL A, N
  DIMENSION A(1:N, *)
  ...
```

The following example shows that you can specify lower bounds for any of the dimensions of an assumed-size array, including the last:

```
SUBROUTINE ASSUME(A)
  REAL A(-4:-2, 4:6, 3:*)
```

Array Elements

Assumed-Rank Specifications

An assumed-rank array is a dummy argument whose rank is inherited from the actual argument associated with it, or it is the associate name of a RANK DEFAULT block of a SELECT RANK construct. It can have zero rank.

You declare an assumed-rank object (a dummy variable) by using DIMENSION(..) or (..)*array bounds* in its declaration.

Its rank is assumed from its effective argument, which means it is passed by descriptor.

An assumed-rank entity must not have the CODIMENSION or VALUE attribute. It can have the CONTIGUOUS attribute.

An assumed-rank variable name must not appear in a designator or expression except as one of the following:

- An actual argument corresponding to a dummy argument that is assumed-rank
- The argument of the C_LOC function in the ISO_C_BINDING intrinsic module
- The first argument in a reference to an intrinsic inquiry function
- The selector of a SELECT RANK construct

If an assumed-size or nonallocatable, nonpointer, assumed-rank array is an actual argument corresponding to a dummy argument that is an INTENT(OUT) assumed-rank array, it must not be polymorphic, finalizable, of a type with an allocatable ultimate component, or of a type for which default initialization is specified.

You can find the rank of an assumed-rank object by using the RANK intrinsic.

If a procedure has an assumed-rank argument, the procedure must have an explicit interface.

When an assumed-rank object is passed from Fortran to a BIND(C) routine, it is passed by C descriptor. A Fortran procedure that has the BIND(C) *language-binding-spec* attribute will also receive an assumed-rank object by C descriptor.

Examples

The following shows an assumed-rank object:

```
SUBROUTINE sub (foo, bar)
! As sub does not have BIND, foo and bar are passed by "normal" descriptor
REAL, DIMENSION(..) :: foo
INTEGER :: bar(..)

INTERFACE
  SUBROUTINE csub (baz) BIND(C)
  REAL, DIMENSION(..) :: baz
  END SUBROUTINE
END INTERFACE

CALL baz(foo)   ! Passed by C descriptor
```

RANK

Deferred-Shape Specifications

A *deferred-shape array* is an array pointer or an allocatable array.

The array specification contains a colon (:) for each dimension of the array. No bounds are specified. The bounds (and shape) of allocatable arrays and array pointers are determined when space is allocated for the array during program execution.

An *array pointer* is an array declared with the POINTER attribute. Its bounds and shape are determined when it is associated with a target by pointer assignment, or when the pointer is allocated by execution of an ALLOCATE statement.

In pointer assignment, the lower bound of each dimension of the array pointer is the result of the LBOUND intrinsic function applied to the corresponding dimension of the target. The upper bound of each dimension is the result of the UBOUND intrinsic function applied to the corresponding dimension of the target.

An actual argument that is a pointer can be associated with a nonpointer dummy argument. Normally, a pointer dummy argument can be associated only with a pointer actual argument. However, a pointer dummy argument with INTENT(IN) can be argument associated with a non-pointer actual argument with the TARGET attribute. During the execution of the procedure, it is pointer associated with the actual argument.

A function result can be declared to have the pointer attribute.

An *allocatable array* is declared with the ALLOCATABLE attribute. Its bounds and shape are determined when the array is allocated by execution of an ALLOCATE statement.

Examples

The following are examples of deferred-shape specifications:

```
REAL, ALLOCATABLE :: A(:,:)       ! Allocatable array
REAL, POINTER :: C(:), D (:,:,:)  ! Array pointers
```

If a deferred-shape array is declared in a DIMENSION or TARGET statement, it must be given the ALLOCATABLE or POINTER attribute in another statement. For example:

```
 DIMENSION P(:, :, :)
 POINTER P

 TARGET B(:,:)
 ALLOCATABLE B
```

If the deferred-shape array is an array of pointers, its size, shape, and bounds are set in an ALLOCATE statement or in the pointer assignment statement when the pointer is associated with an allocated target. A pointer and its target must have the same rank.

For example:

```
 REAL, POINTER :: A(:,:), B(:), C(:,:)
 INTEGER, ALLOCATABLE :: I(:)
 REAL, ALLOCATABLE, TARGET :: D(:, :), E(:)
 ...
 ALLOCATE (A(2, 3), I(5), D(SIZE(I), 12), E(98) )
 C => D              ! Pointer assignment statement
 B => E(25:56)       ! Pointer assignment to a section
                     !   of a target
```

A pointer dummy argument with INTENT(IN) can be argument associated with a non-pointer actual argument with the TARGET attribute. It is pointer associated with the actual argument, so the following example prints "17".

```
program test
   integer, target :: j = 17
   call f (j)
contains
   subroutine f (i)
   integer, intent (in), pointer :: i
   print *,i
   end subroutine f
end program test
```

UBOUND intrinsic function

Implied-Shape Specifications

Short Description

An *implied-shape array* is a named constant that takes its shape from the constant expression in its declaration. An implied-shape specification takes the following form:

([*dl*:] *du* [, [*dl*:] *du*] ...)

dl	Is a specification expression indicating the lower bound of the dimension. The expression can have a positive, negative, or zero value. If necessary, the value is converted to integer type. If the lower bound is not specified, it is assumed to be 1.
du	Is the upper bound of the dimension or *.

The constant expression in the implied-shape declaration must be an array.

The rank of the array must be the same as the rank of the constant expression in its declaration.

The extent of each dimension of an implied-shape array is the same as the extent of the corresponding dimension of the constant expression.

The value of the upper bound is 1 less than the sum of the lower bound and the extent.

Examples

The following examples show implied-shape specifications:

```
INTEGER, PARAMETER :: R(*) = [1,2,3]
! means SHAPE (R) is [3]

integer, parameter :: x (0:*,1:*) = reshape ( [1,2,3,4], [2,2] )
! means dimensions of X are 0 to 1 and 1 to 2

REAL :: M (2:*, -1:*)
PARAMETER (M = RESHAPE ([R,R], [3,2]))
! means dimensions of M are 2 to 4 and -1 to 0

integer, parameter :: Y (0:*,1:2) = reshape ( [1,2,3,4], [2,2] )
! means dimensions of Y are 0 to 1 and 1 to 2
```

Effects of Equivalency and Interaction with COMMON Statements

When you make an element of one array equivalent to an element of another array, the EQUIVALENCE statement also sets equivalences between the other elements of the two arrays.

When you make one character substring equivalent to another character substring, the EQUIVALENCE statement also sets associations between the other corresponding characters in the character entities.

A common block can extend beyond its original boundaries if variables or arrays are associated with entities stored in the common block. However, a common block can only extend beyond its last element; the extended portion cannot precede the first element in the block.

COMMON and EQUIVALENCE are obsolescent language features in Standard Fortran.

For more information, see the topics in this section.

Making Arrays Equivalent

When you make an element of one array equivalent to an element of another array, the EQUIVALENCE statement also sets equivalences between the other elements of the two arrays. Thus, if the first elements of two equal-sized arrays are made equivalent, both arrays share the same storage. If the third element of a 7-element array is made equivalent to the first element of another array, the last five elements of the first array overlap the first five elements of the second array.

Two or more elements of the same array should not be associated with each other in one or more EQUIVALENCE statements. For example, you cannot use an EQUIVALENCE statement to associate the first element of one array with the first element of another array, and then attempt to associate the fourth element of the first array with the seventh element of the other array.

Consider the following example:

```
DIMENSION TABLE (2,2), TRIPLE (2,2,2)
EQUIVALENCE(TABLE(2,2), TRIPLE(1,2,2))
```

These statements cause the entire array TABLE to share part of the storage allocated to TRIPLE. The following table shows how these statements align the arrays:

Equivalence of Array Storage

Array TRIPLE		Array TABLE	
Array Element	**Element Number**	**Array Element**	**Element Number**
TRIPLE(1,1,1)	1		
TRIPLE(2,1,1)	2		
TRIPLE(1,2,1)	3		
TRIPLE(2,2,1)	4	TABLE(1,1)	1
TRIPLE(1,1,2)	5	TABLE(2,1)	2
TRIPLE(2,1,2)	6	TABLE(1,2)	3
TRIPLE(1,2,2)	7	TABLE(2,2)	4
TRIPLE(2,2,2)	8		

Each of the following statements also aligns the two arrays as shown in the above table:

```
EQUIVALENCE(TABLE, TRIPLE(2,2,1))
EQUIVALENCE(TRIPLE(1,1,2), TABLE(2,1))
```

You can also make arrays equivalent with nonunity lower bounds. For example, an array defined as A(2:3,4) is a sequence of eight values. A reference to A(2,2) refers to the third element in the sequence. To make array A(2:3,4) share storage with array B(2:4,4), you can use the following statement:

```
EQUIVALENCE(A(3,4), B(2,4))
```

The entire array A shares part of the storage allocated to array B. The following table shows how these statements align the arrays. The arrays can also be aligned by the following statements:

```
EQUIVALENCE(A, B(4,1))
EQUIVALENCE(B(3,2), A(2,2))
```

Equivalence of Arrays with Nonunity Lower Bounds

Array B		Array A	
Array Element	**Element Number**	**Array Element**	**Element Number**
B(2,1)	1		
B(3,1)	2		
B(4,1)	3	A(2,1)	1
B(2,2)	4	A(3,1)	2
B(3,2)	5	A(2,2)	3
B(4,2)	6	A(3,2)	4
B(2,3)	7	A(2,3)	5
B(3,3)	8	A(3,3)	6
B(4,3)	9	A(2,4)	7
B(2,4)	10	A(3,4)	8
B(3,4)	11		
B(4,4)	12		

Only in the EQUIVALENCE statement can you identify an array element with a single subscript (the linear element number), even though the array was defined as multidimensional. For example, the following statements align the two arrays as shown in the above table:

```
DIMENSION B(2:4,1:4), A(2:3,1:4)
EQUIVALENCE(B(6), A(4))
```

Making Substrings Equivalent

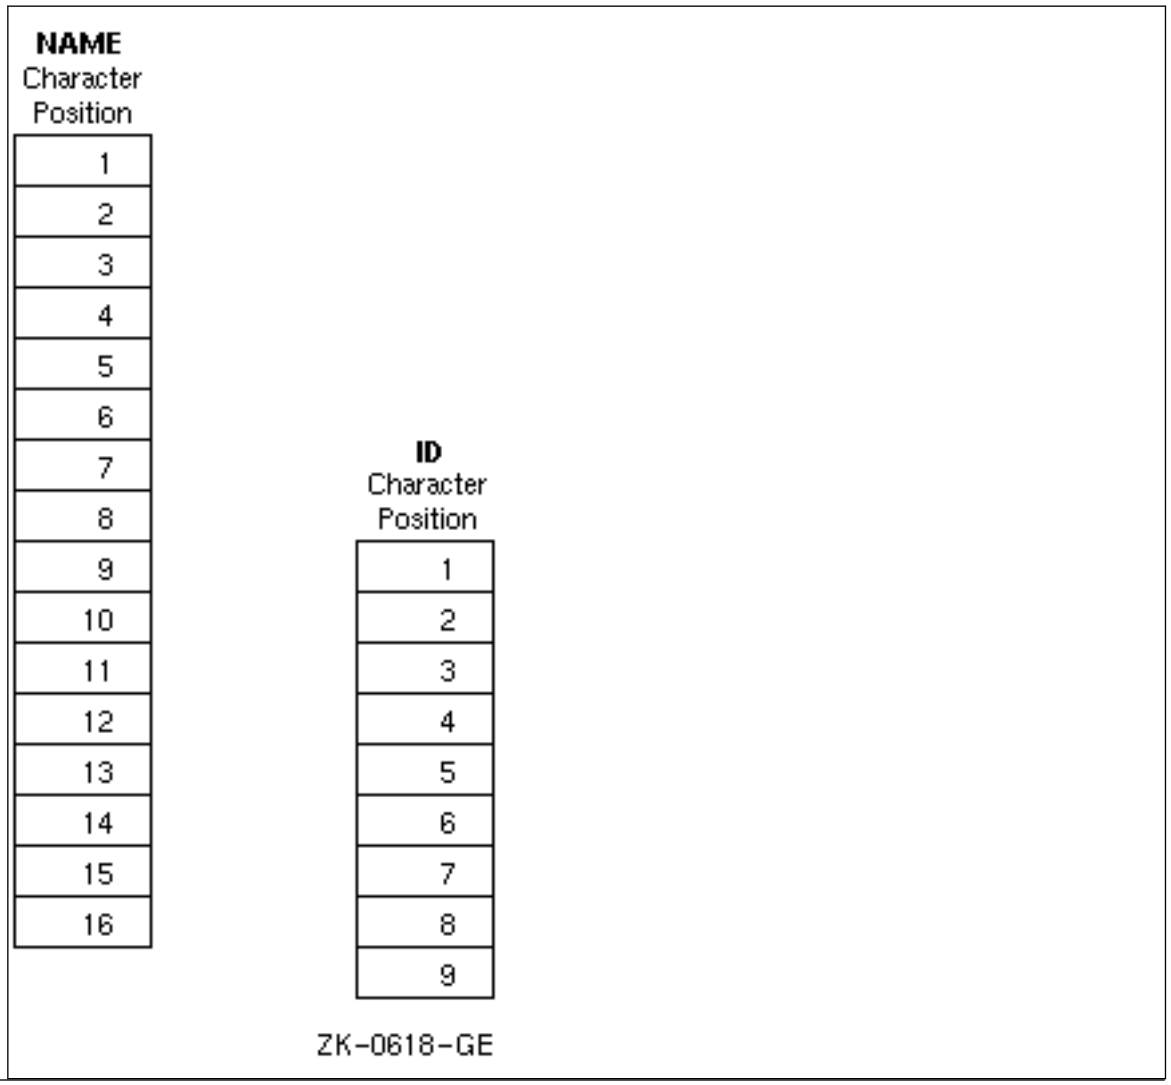
When you make one character substring equivalent to another character substring, the EQUIVALENCE statement also sets associations between the other corresponding characters in the character entities; for example:

```
CHARACTER NAME*16, ID*9
EQUIVALENCE(NAME(10:13), ID(2:5))
```

These statements cause character variables NAME and ID to share space (see the following figure). The arrays can also be aligned by the following statement:

```
EQUIVALENCE(NAME(9:9), ID(1:1))
```

Equivalence of Substrings

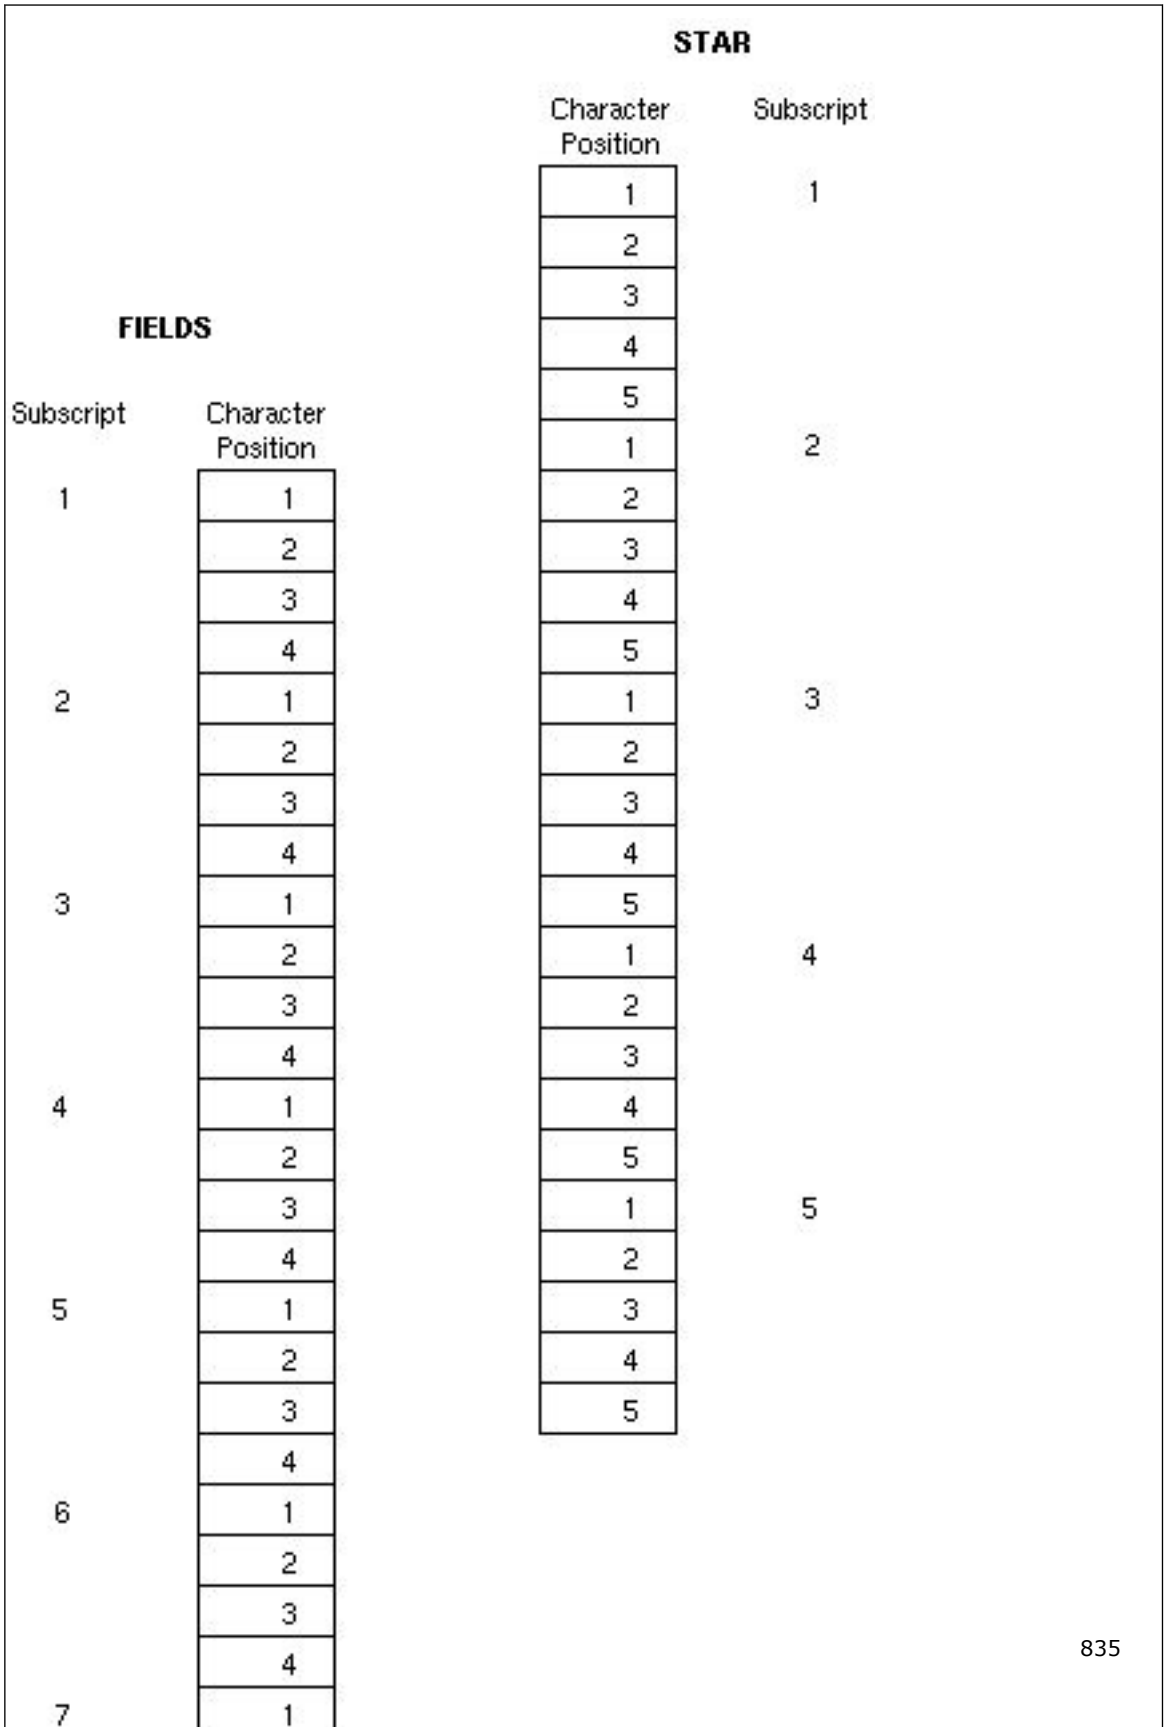


If the character substring references are array elements, the EQUIVALENCE statement sets associations between the other corresponding characters in the complete arrays.

Character elements of arrays can overlap at any character position. For example, the following statements cause character arrays FIELDS and STAR to share storage (see the following figure).

```
CHARACTER FIELDS(100)*4, STAR(5)*5
EQUIVALENCE(FIELDS(1)(2:4), STAR(2)(3:5))
```

Equivalence of Character Arrays



The EQUIVALENCE statement cannot assign the same storage location to two or more substrings that start at different character positions in the same character variable or character array. The EQUIVALENCE statement also cannot assign memory locations in a way that is inconsistent with the normal linear storage of character variables and arrays.

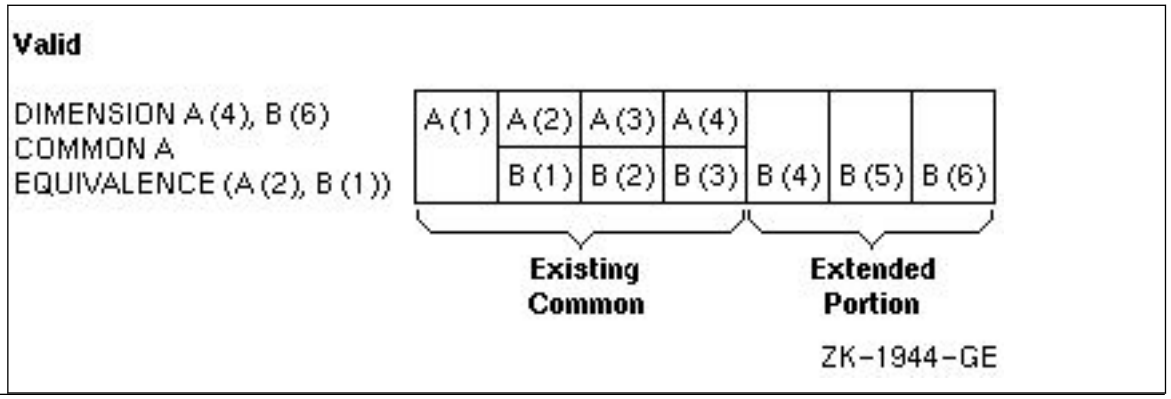
EQUIVALENCE and COMMON Interaction

A common block can extend beyond its original boundaries if variables or arrays are associated with entities stored in the common block. However, a common block can only extend beyond its last element; the extended portion cannot precede the first element in the block.

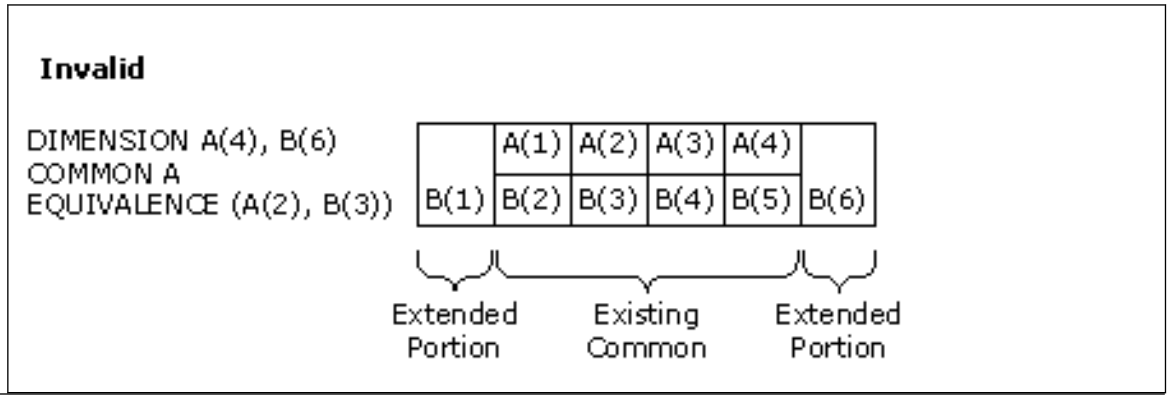
Examples

The following two figures demonstrate valid and invalid extensions of the common block, respectively.

A Valid Extension of a Common Block



An Invalid Extension of a Common Block



The second example is invalid because the extended portion, B(1), precedes the first element of the common block.

The following example shows a valid EQUIVALENCE statement and an invalid EQUIVALENCE statement in the context of a common block.

```
COMMON A, B, C
DIMENSION D(3)
EQUIVALENCE(B, D(1))      ! Valid, because common block is extended
                          !   from the end.

COMMON A, B, C
```

```
DIMENSION D(3)
EQUIVALENCE(B, D(3))      ! Invalid, because D(1) would extend common
                          !   block to precede A's location.
```

Dynamic Allocation

Data objects can be static or dynamic. If a data object is static, a fixed amount of memory storage is created for it at compile time and is not freed until the program exits. If a data object is dynamic, memory storage for the object can be created (allocated), altered, or freed (deallocated) as a program executes.

Pointers, classes, deferred length character, allocatable scalars and arrays, and automatic arrays are dynamic data objects.

No storage space is created for a pointer until it is allocated with an ALLOCATE statement or until it is assigned to an allocated target. The storage space allocated is uninitialized.

An ALLOCATE statement can also be used to create storage for an allocatable array. A DEALLOCATE statement can be used to free the storage space reserved in a previous ALLOCATE statement. It also causes any pointers to become disassociated.

A pointer can be dynamically disassociated from a target by using a NULLIFY statement.

Automatic arrays differ from allocatable arrays in that they are automatically allocated and deallocated whenever you enter or leave a procedure, respectively.

Dynamic allocation occurs at run time and is handled by the Fortran Run-Time Library. There are several restrictions on allocation and deallocation that must be observed when these operations on a specific object are performed in program units that are separately compiled. When allocation and deallocation of an object are split between procedures in static code and dynamic shared libraries (.so files on Linux*) or dynamic-link libraries (DLLs on Windows*), the following applies:

- If the dynamic library is compiled with the `[q or Q]openmp` compiler option, then the main program must be compiled and linked with `[q or Q]openmp` to include the OpenMP memory handling routines in the program.
- If the dynamic library allocates data in High bandwidth (HBW) memory on Linux*, then the program must be linked with the `libmemkind` library to include the HBW memory handling routines in the program.

> **NOTE**
> Dynamic memory allocation is limited by several factors, including swap file size and memory requirements of other applications that are running. Dynamic allocations that are too large or otherwise attempt to use the protected memory of other applications result in General Protection Fault errors. If you encounter an unexpectedly low limit, you might need to reset your virtual memory size through the Control Panel or redefine the swap file size.
>
> Some programming techniques can help minimize memory requirements, such as using one large array instead of two or more individual arrays. Allocated arrays that are no longer needed should be deallocated.

TARGET

Effects of Allocation

When you allocate allocatable variables, allocatable arrays, and pointer targets, it can have various effects on your program.

For more information, see the topics in this section.

Allocation of Allocatable Variables

The status of an allocatable variable becomes "allocated" under the following conditions:

- If it is allocated by an ALLOCATE statement
- If it is allocated during assignment
- If it is allocated by the intrinsic subroutine MOVE_ALLOC

An allocatable variable with allocated status can be referenced, defined, or deallocated; allocating it causes an error condition in the ALLOCATE statement. The intrinsic function ALLOCATED returns TRUE for such a variable.

The status of an allocatable variable becomes "unallocated" under the following conditions:

- If it is not allocated
- If it is deallocated
- If it is unallocated by the intrinsic subroutine MOVE_ALLOC

An allocatable variable with unallocated status must not be referenced or defined. It must not be supplied as an actual argument corresponding to a nonallocatable dummy argument, except to certain intrinsic inquiry functions. It can be allocated with the ALLOCATE statement. Deallocating it causes an error condition in the DEALLOCATE statement. The intrinsic function ALLOCATED returns FALSE for such a variable.

At the beginning of execution of a program, allocatable variables are unallocated.

When the allocation status of an allocatable variable changes, the allocation status of any associated allocatable variable also changes accordingly. Allocation of an allocatable variable establishes values for the deferred type parameters of all associated allocatable variables.

An unsaved allocatable local variable of a procedure has a status of unallocated at the beginning of each invocation of the procedure. An unsaved local variable of a construct has a status of unallocated at the beginning of each execution of the construct.

When an object of derived type is created by an ALLOCATE statement, any allocatable ultimate components have an allocation status of unallocated unless the SOURCE= specifier appears and the corresponding component of the SOURCE= expression is allocated.

The intrinsic function ALLOCATED can be used to determine whether a variable is allocated or unallocated.

Allocation of Allocatable Arrays

The bounds (and shape) of an allocatable array are determined when it is allocated. Subsequent redefinition or undefinition of any entities in the bound expressions does not affect the array specification.

If the lower bound is greater than the upper bound, that dimension has an extent of zero, and the array has a size of zero. If the lower bound is omitted, it is assumed to be 1.

When an array is allocated, it is definable. If you try to allocate a currently allocated allocatable array, an error occurs.

If an allocatable variable is a coarray, the corank is declared, but the cobounds are determined when it is allocated.

The intrinsic function ALLOCATED can be used to determine whether an allocatable array is currently allocated; for example:

```
REAL, ALLOCATABLE :: E(:,:)
...
IF (.NOT. ALLOCATED(E)) ALLOCATE(E(2:4,7))
```

Allocation Status

During program execution, the allocation status of an allocatable array is one of the following:

- Not currently allocated

  The array was never allocated or the last operation on it was a deallocation. Such an array must not be referenced or defined.
- Currently allocated

  The array was allocated by an ALLOCATE statement. Such an array can be referenced, defined, or deallocated.

If an allocatable array has the SAVE attribute, it has an initial status of "not currently allocated". If the array is then allocated, its status changes to "currently allocated". It keeps that status until the array is deallocated.

If an allocatable array *does not* have the SAVE attribute, it has the status of "not currently allocated" at the beginning of each invocation of the procedure. If the array's status changes to "currently allocated", it is deallocated if the procedure is terminated by execution of a RETURN or END statement.

Example: Allocating Virtual Memory

The following example shows a program that performs virtual memory allocation. This program uses Fortran standard-conforming statements instead of calling an operating system memory allocation routine.

```
! Program accepts an integer and displays square root values

  INTEGER(4) :: N
  READ (5,*) N                          ! Reads an integer value
  CALL MAT(N)
  END

! Subroutine MAT uses the typed integer value to display the square
! root values of numbers from 1 to N (the number read)

  SUBROUTINE MAT(N)
  REAL(4), ALLOCATABLE :: SQR(:)        ! Declares SQR as a one-dimensional
                                        !          allocatable array
  ALLOCATE (SQR(N))                     ! Allocates array SQR

  DO J=1,N
     SQR(J) = SQRT(FLOATJ(J))           ! FLOATJ converts integer to REAL
  ENDDO

  WRITE (6,*) SQR                       ! Displays calculated values
  DEALLOCATE (SQR)                      ! Deallocates array SQR
  END SUBROUTINE MAT
```

ALLOCATE statement

Allocation of Pointer Targets

When a pointer is allocated, the pointer is associated with a target and can be used to reference or define the target. The target can be an array or a scalar, depending on how the pointer was declared.

Other pointers can become associated with the pointer target (or part of the pointer target) by pointer assignment.

In contrast to allocatable arrays, a pointer can be allocated a new target even if it is currently associated with a target. The previous association is broken and the pointer is then associated with the new target.

If the previous target was created by allocation, it becomes inaccessible unless it can still be referred to by other pointers that are currently associated with it.

The intrinsic function ASSOCIATED can be used to determine whether a pointer is currently associated with a target. The association status of the pointer must be *defined*. For example:

```
REAL, TARGET  :: TAR(0:50)
REAL, POINTER :: PTR(:)
PTR => TAR
...
IF (ASSOCIATED(PTR,TAR))...
```

See Also

POINTER statement and attribute
Pointer assignments
ASSOCIATED intrinsic function

Effects of Deallocation

When you deallocate allocatable variables, allocatable arrays, and pointer targets, it can have various effects on your program.

For more information, see the topics in this section.

Deallocation of Allocatable Variables

Deallocating an unallocated allocatable variable causes an error condition in the DEALLOCATE statement.

Deallocating an allocatable variable with the TARGET attribute causes the pointer association status of any pointer associated with it to become undefined.

When the execution of a procedure is terminated by execution of a RETURN or END statement, an unsaved allocatable local variable of the procedure retains its allocation and definition status if it is a function result variable or a subobject of one; otherwise, it is deallocated.

If an executable construct references a function whose result is either allocatable or a structure with a subobject that is allocatable, and the function reference is executed, an allocatable result and any subobject that is an allocated allocatable entity in the result returned by the function is deallocated after execution of the innermost executable construct containing the reference.

If a function whose result is either allocatable or a structure with an allocatable subobject is referenced in the specification part of a scoping unit, and the function reference is executed, an allocatable result and any subobject that is an allocated allocatable entity in the result returned by the function is deallocated before execution of the executable constructs of the scoping unit.

When a procedure is invoked, any allocated allocatable object that is an actual argument corresponding to an INTENT (OUT) allocatable dummy argument is deallocated. Any allocated allocatable object that is a subobject of an actual argument corresponding to an INTENT (OUT) dummy argument is deallocated.

When an intrinsic assignment statement is executed, any noncoarray allocated allocatable subobject of the variable is deallocated before the assignment takes place.

When a variable of derived type is deallocated, any allocated allocatable subobject is deallocated.

If an allocatable component is a subobject of a finalizable object, that object is finalized before the component is automatically deallocated.

The effect of automatic deallocation is the same as that of a DEALLOCATE statement without a *dealloc-opt* argument.

When a DEALLOCATE statement is executed for which an object is a coarray, there is an implicit synchronization of all images. On each image, execution of the segment following the statement is delayed until all other images have executed the same statement the same number of times. If the coarray is a dummy argument, its ultimate argument must be the same coarray on every image.

There is also an implicit synchronization of all images in association with the deallocation of a coarray or coarray subcomponent caused by the execution of a RETURN or END statement.

The intrinsic function ALLOCATED can be used to determine whether a variable is allocated or unallocated.

Consider the following example:

```
SUBROUTINE PROCESS
   REAL, ALLOCATABLE :: TEMP(:)
   REAL, ALLOCATABLE, SAVE :: X(:)
   ...
END SUBROUTINE PROCESS
```

Upon return from subroutine PROCESS, the allocation status of X is preserved because X has the SAVE attribute. TEMP does not have the SAVE attribute, so it will be deallocated if it was allocated. On the next invocation of PROCESS, TEMP will have an allocation status of unallocated.

Deallocation of Allocatable Arrays

If the DEALLOCATE statement specifies an array that is not currently allocated, an error occurs.

If an allocatable array with the TARGET attribute is deallocated, the association status of any pointer associated with it becomes undefined.

If a RETURN or END statement terminates a procedure, an allocatable array has one of the following allocation statuses:

- It keeps its previous allocation and association status if the following is true:
  - It has the SAVE attribute.
  - It is in the scoping unit of a module that is accessed by another scoping unit that is currently executing.
  - It is accessible by host association.
- It remains allocated if it is accessed by use association.
- Otherwise, its allocation status is deallocated.

The intrinsic function ALLOCATED can be used to determine whether an allocatable array is currently allocated; for example:

```
SUBROUTINE TEST
  REAL, ALLOCATABLE, SAVE :: F(:,:)

  REAL, ALLOCATABLE :: E(:,:,:)
  ...
  IF (.NOT. ALLOCATED(E)) ALLOCATE(E(2:4,7,14))
END SUBROUTINE TEST
```

Note that when subroutine TEST is exited, the allocation status of F is maintained because F has the SAVE attribute. Since E does not have the SAVE attribute, it is deallocated. On the next invocation of TEST, E will have the status of "not currently allocated".

See Also

Host association
TARGET statement and attribute
RETURN statement
END statement
SAVE statement

Deallocation of Pointer Targets

A pointer must not be deallocated unless it has a defined association status. If the DEALLOCATE statement specifies a pointer that has undefined association status, or a pointer whose target was not created by allocation, an error occurs.

A pointer must not be deallocated if it is associated with an allocatable array, or it is associated with a portion of an object (such as an array element or an array section).

If a pointer is deallocated, the association status of any other pointer associated with the target (or portion of the target) becomes undefined.

Execution of a RETURN or END statement in a subprogram causes the pointer association status of any pointer declared or accessed in the procedure to become undefined, unless any of the following applies to the pointer:

- It has the SAVE attribute.
- It is in the scoping unit of a module that is accessed by another scoping unit which is currently executing.
- It is accessible by host association.
- It is in blank common.
- It is in a named common block that appears in another scoping unit that is currently executing.
- It is the return value of a function declared with the POINTER attribute.

If the association status of a pointer becomes undefined, it cannot subsequently be referenced or defined.

Examples

The following example shows deallocation of a pointer:

```
INTEGER ERR
REAL, POINTER :: PTR_A(:)
...
ALLOCATE (PTR_A(10), STAT=ERR)
...
DEALLOCATE(PTR_A)
```

END statement
SAVE statement

Execution Control

Execution of a program consists of the asynchronous execution of the program in a fixed number of one or more of its images. Each image has its own execution environment, including floating-point status, a set of data objects, input/output units, and procedure pointers.

A program normally executes statements in the order in which they are written. Executable control constructs and statements, and procedure invocations, modify this normal execution by transferring control to another statement in the program, or by selecting blocks (groups) of constructs and statements for execution or repetition.

Procedures may be invoked by the CALL statement (subroutine), during expression evaluation (function), or as part of data definition and handling (user-defined operators and FINAL procedures). There are many ways to define a procedure: for example, external, internal, contained, type-bound, defined operator or assignment, and module. All procedures have one entry point; procedures usually return to their caller.

The control constructs ASSOCIATE, CASE, DO, IF, SELECT RANK, and SELECT TYPE contain blocks and can be named. The name must be a unique identifier in the scoping unit, and must appear on the initial line and terminal line of the construct. On the initial line, the name is separated from the statement keyword by a colon (:).

A block can contain any executable Fortran statement except an END statement. You can transfer control out of a block, but you cannot transfer control into another block.

DO loops cannot partially overlap blocks. The DO statement and its terminal statement must appear together in a statement block.

The following are execution control statements or constructs:

- ASSOCIATE construct

  Creates a temporary association between a named entity and a variable or the value of an expression. The association lasts for the duration of the block.
- BLOCK construct

  Executes a block of statements or constructs that can contain declarations.
- CALL statement

  Transfers control to a subroutine subprogram.
- CASE construct

  Conditionally executes one block of constructs or statements depending on the value of a scalar expression in a SELECT CASE statement.
- CONTINUE statement

  Primarily used to terminate a labeled DO construct when the construct would otherwise end improperly with either a GO TO, arithmetic IF, or other prohibited control statement.
- CRITICAL construct

  Limits execution of a block to one image at a time.
- DO construct

  Controls the repeated execution of a block of statements or constructs. The following statements are used in DO constructs:

  - DO CONCURRENT statement

    Specifies that there are no data dependencies between the iterations of a DO loop.
  - DO WHILE statement

    Executes the range of a DO construct while a specified condition remains true.
  - CYCLE statement

    Interrupts the current execution cycle of the innermost (or named) DO construct.
  - EXIT statement

    Terminates execution of a DO construct
- END statement

  Marks the end of a program unit.
- IF construct and IF statement

  The IF construct conditionally executes one block of statements or constructs. The IF statement conditionally executes one statement. The decision to transfer control or to execute the statement or block is based on the evaluation of a logical expression within the IF statement or construct.
- PAUSE statement

  Temporarily suspends program execution until the user or system resumes execution.

  These statements are deleted features in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.
- RETURN statement

  Transfers control from a subprogram to the calling program unit.
- SELECT RANK construct

  Selects for execution at most one of its constituent blocks based on the rank of an assumed-rank variable.

- SELECT TYPE construct

  Selects for execution at most one of its constituent blocks based on the dynamic type of an expression specified.
- STOP and ERROR STOP statement

  The STOP statement initiates normal termination of an image before the execution of an END statement of the main program. The ERROR STOP statement initiates error termination.

Program Termination

Program termination may involve flushing I/O buffers, closing open I/O files, writing of a STOP code or an ERROR STOP code, or reporting an error status on one or more images. There are two types of image termination, normal termination and error termination.

Normal termination occurs when an image executes a STOP statement or an END [PROGRAM] statement. If there are multiple images running, execution of STOP or END [PROGRAM] statement effects only the image that executes the statement; it has no effect on other images. When an image initiates normal termination, its image status becomes STOPPED, and it waits until all other active images initiate normal termination at which time all images terminate execution. While an image has the status STOPPED, its coarrays are still accessible for reference or definition by other active images.

Error termination of one image causes termination of all other images. Error termination is not initiated if an error condition occurs during the execution of an I/O statement which specifies either an IOSTAT= or ERR= specifier, during the execution of an image control statement that specifies a STAT= specifier, or during a reference to an intrinsic function with a present STAT argument. Otherwise, if an error condition occurs, error termination is initiated.

A program terminates execution when all images that have not failed terminate execution.

Branch Statements Overview

Branching affects the normal execution sequence by transferring control to a labeled statement in the same scoping unit. The transfer statement is called the *branch statement*, while the statement to which the transfer is made is called the *branch target statement*. A branch target statement inside a construct may only be branched to from within the same block of the construct that contains the branch target statement.

Any executable statement can be a branch target statement, except for the following:

- CASE statement
- ELSE statement
- ELSE IF statement
- END FORALL statement
- END WHERE statement
- RANK case statement
- A statement in a FORALL or WHERE construct
- A *type-guard* statement (TYPE IS, CLASS IS, or CLASS DEFAULT)

Certain restrictions apply to the following statements:

Statement	Restriction
DO terminal statement	The branch must be taken from within its nonblock DO construct[1].
END ASSOCIATE	The branch must be taken from within its ASSOCIATE construct.
END BLOCK	The branch must be taken from within its BLOCK construct.
END DO	The branch must be taken from within its block DO construct.

Statement	Restriction
END IF	The branch should be taken from within its IF construct[2].
END SELECT	The branch must be taken from within its SELECT CASE, SELECT RANK, or SELECT TYPE construct.

[1]If the terminal statement is shared by more than one nonblock DO construct, the branch can only be taken from within the innermost DO construct.

[2]You can branch to an END IF statement from outside the IF construct; this is a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

The following are branch statements:

- GOTO - Unconditional statement

  Transfers control to the same branch target statement every time it executes.
- GOTO - COMPUTED statement

  Transfers control to one of a set of labeled branch target statements based on the value of an expression.
- CALL statement with an alternate return specified

  Transfers control to one of the alternate return branch target statements based on the value of the expression on the RETURN statement executed in the called subroutine to return control to the caller.
- An input/output statement with an END=, EOR=, or ERR= specifier

  Transfers control to the specified labeled branch target statement if an end of file condition (END=), an end of record condition (EOR=), or an error condition (ERR=) occurs during execution of the input/output statement.
- ASSIGN and assigned GO TO statements

  Assigns a label to an integer variable. Subsequently, this variable can be used as a branch target statement by an assigned GO TO statement or as a format specifier in a formatted input/output statement.

  These statements are deleted features in Fortran 95. Intel® Fortran fully supports features deleted in Fortran 95.
- IF - Arithmetic statement

  Conditionally transfers control to one of three statements, based on the value of an arithmetic expression.

Effects of DO Constructs

This section discusses ways you can use DO loops and their effects on your program.

For more information, see the topics in this section.

Iteration Loop Control

DO iteration loop control takes the following form:

do-var = *expr1*, *expr2* [, *expr3*]

do-var	Is the name of a scalar variable of type integer or real. It cannot be the name of an array element or structure component.
expr	Is a scalar numeric expression of type integer, logical, or real. If it is not the same type as *do-var*, it is converted to that type.

Description

A DO variable or expression of type real is a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

The following steps are performed in iteration loop control:

1. The expressions *expr1*, *expr2*, and *expr3* are evaluated to respectively determine the initial, terminal, and increment parameters.

   The increment parameter (*expr3*) is optional and must not be zero. If an increment parameter is not specified, it is assumed to be of type default integer with a value of 1.
2. The DO variable (*do-var*) becomes defined with the value of the initial parameter (*expr1*).
3. The iteration count is determined as follows:

```
MAX(INT((expr2 - expr1 + expr3)/expr3), 0)
```

   The iteration count is zero if either of the following is true:

```
expr1 > expr2 and expr3 > 0
expr1 < expr2 and expr3 < 0
```

4. The iteration count is tested. If the iteration count is zero, the loop terminates and the DO construct becomes inactive. (Compiler option f66 can affect this.) If the iteration count is nonzero, the range of the loop is executed.
5. The iteration count is decremented by one, and the DO variable is incremented by the value of the increment parameter, if any.

After termination, the DO variable retains its last value (the one it had when the iteration count was tested and found to be zero).

The DO variable must not be redefined or become undefined during execution of the DO range.

If you change variables in the initial, terminal, or increment expressions during execution of the DO construct, it does not affect the iteration count. The iteration count is fixed each time the DO construct is entered.

Examples

The following example specifies 25 iterations:

```
DO 100 K=1,50,2
```

K=49 during the final iteration, K=51 after the loop.

The following example specifies 27 iterations:

```
DO 350 J=50,-2,-2
```

J=-2 during the final iteration, J=-4 after the loop.

The following example specifies 9 iterations:

```
DO NUMBER=5,40,4
```

NUMBER=37 during the final iteration, NUMBER=41 after the loop. The terminating statement of this DO loop must be END DO.

Nested DO Constructs

A DO construct can contain one or more complete DO constructs (loops). The range of an inner nested DO construct must lie completely within the range of the next outer DO construct. Nested nonblock DO constructs can share a labeled terminal statement.

The following figure shows correctly and incorrectly nested DO constructs:

In a nested DO construct, you can transfer control from an inner construct to an outer construct. However, you cannot transfer control from an outer construct to an inner construct.

If two or more nested DO constructs share the same terminal statement, you can transfer control to that statement only from within the range of the innermost construct. Any other transfer to that statement constitutes a transfer from an outer construct to an inner construct, because the shared statement is part of the range of the innermost construct.

When the nested DO constructs contain no statements between the DO statements in the nest of DO constructs, the nest is called "perfectly nested". When perfectly nested DO constructs are modified by a COLLAPSE clause in any of these OpenMP* directives:

- !$OMP DISTRIBUTE
- !$OMP DO
- !$OMP SIMD

There are restrictions on which general compiler directives (see General Compiler Directives) and OpenMP Fortran compiler directives (see OpenMP Fortran Compiler Directives) can appear before the DO statements in the nested DO construct:

- Any OpenMP or general directives that are allowed to affect DO loops are allowed prior to the first DO loop of the "perfectly nested" DO construct.
- It is an error if any of these directives are between any of the perfectly nested DO loop statements for the loops affected by the COLLAPSE clause.

Examples

In the following example, COLLAPSE (1) on affects the DO I loop. Therefore general directives before the DO J loop, which is at level 2, are allowed:

```
!$OMP SIMD collapse (1)
!dir$ prefetch  …           ! this is allowed since it is before the start
                            !    of the perfectly nested DO construct

 do i = …
     !dir$ loop count …     ! this is allowed since collapse only applies
                            !    to the i-loop, not the j-loop
      do j = …
      enddo                 ! end for j-loop
 enddo                      ! end for i-loop
```

In the following example, COLLAPSE (2) affects the DO I loop and the DO J loop but not the DO k loop.

```
!$OMP SIMD collapse (2)
!dir$ prefetch  …           ! this is allowed since it is before the start
                            !    of the perfectly nested DO construct
 do i = …
    do j = …
       !dir$ loop count …   ! this is allowed since collapse only applies to
                            !   the i-loop and the j-loop, not the k-loop
        do k= ….
        enddo               ! end for k-loop
     enddo                  ! end for j-loop
 enddo                      ! end for i-loop
```

In the following example, COLLAPSE (2) affects the DO I loop and the DO J loop so there can be no directives before the DO J loop.

```
!$OMP SIMD collapse (2)
!dir$ prefetch  …           ! this is allowed since it is before the start
                            !    of the perfectly nested DO construct
 do i = …
    !dir$ loop count …      ! this is not allowed: it is breaks the perfectness
                            !    of the  i-loop and the nj-loop collapsing
    do j = …
    enddo                   ! end for j-loop
 enddo                      ! end for i-loop
```

Rules for General Directives that Affect DO loops

Extended Range

A DO construct has an extended range if both of the following are true:

- The DO construct contains a control statement that transfers control out of the construct.
- Another control statement returns control back into the construct after execution of one or more statements.

The range of the construct is extended to include all executable statements between the destination statement of the first transfer and the statement that returns control to the construct.

The following rules apply to a DO construct with extended range:

- A transfer into the range of a DO statement is permitted only if the transfer is made from the extended range of that DO statement.
- The extended range of a DO statement must not change the control variable of the DO statement.

The following figure shows valid and invalid extended range control transfers:

Control Transfers and Extended Range

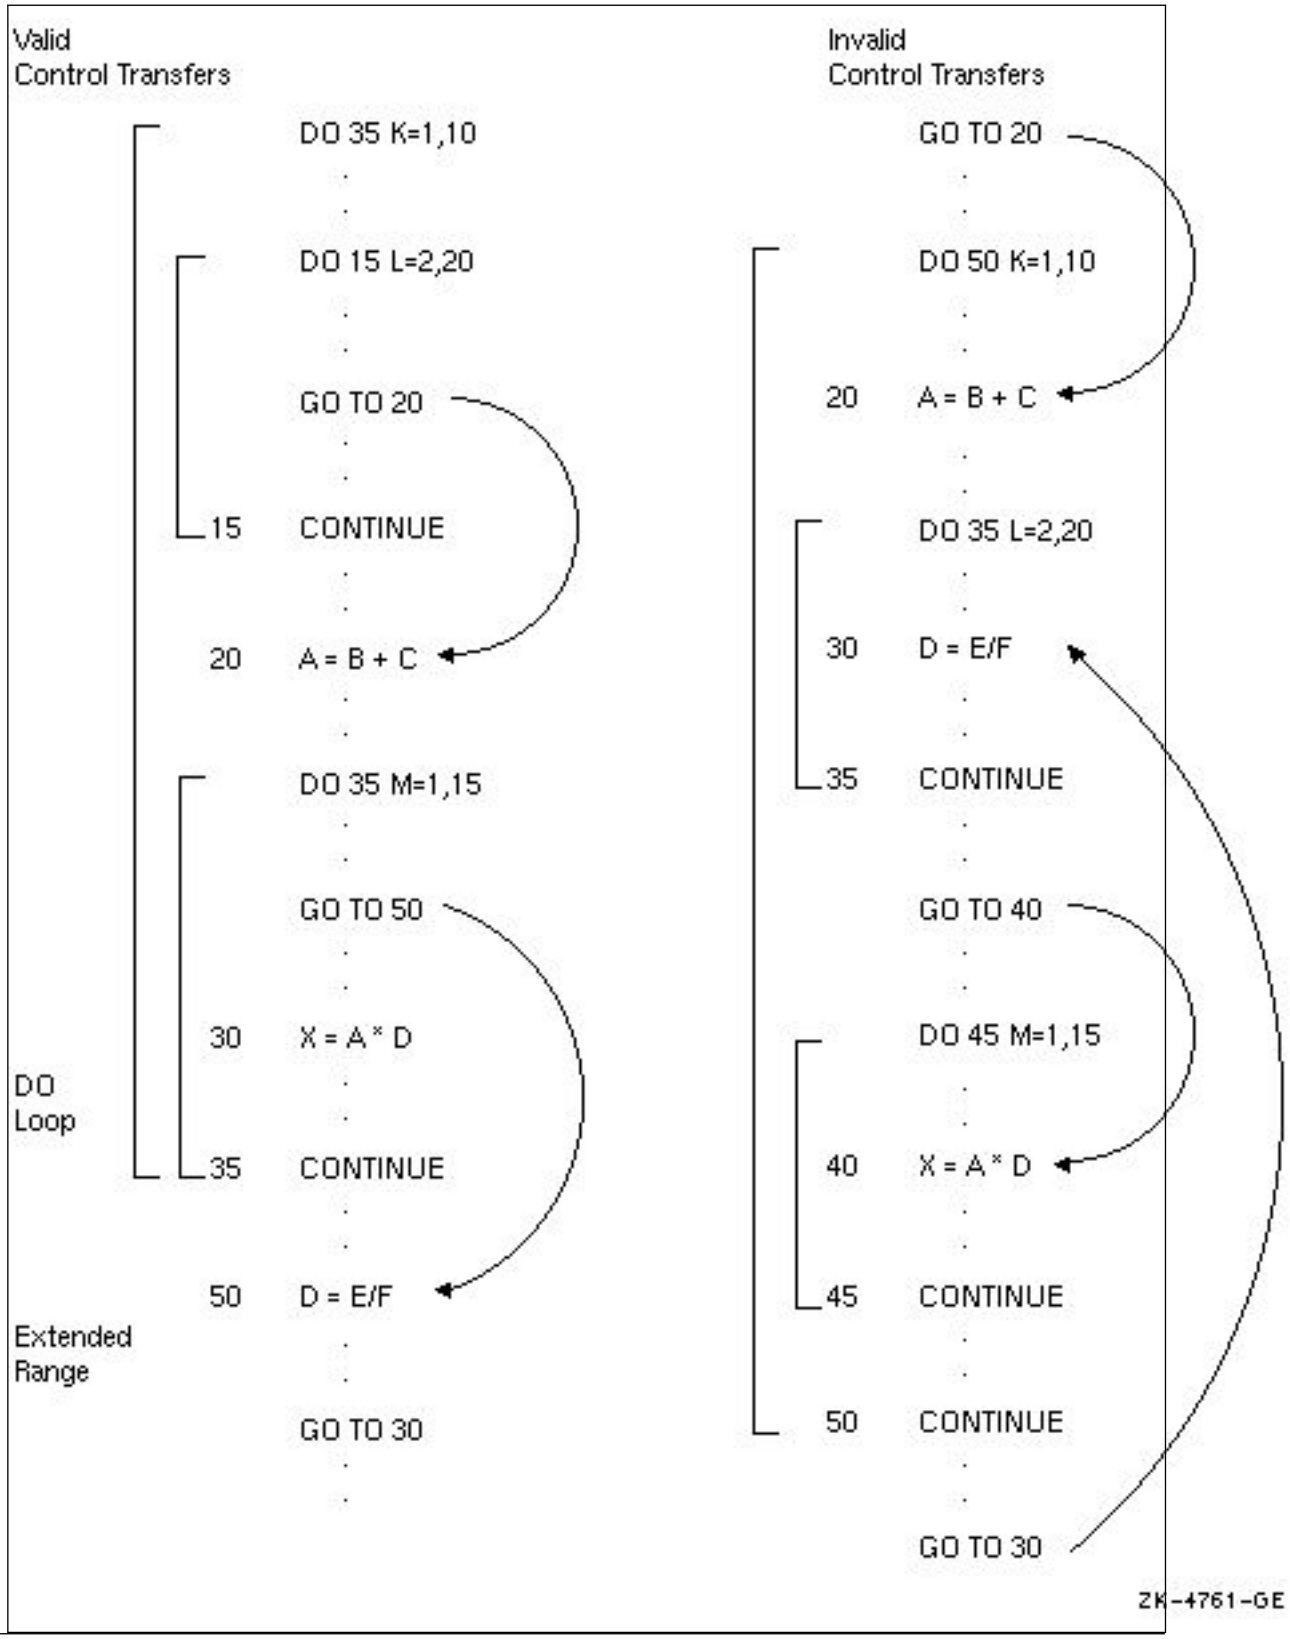

Image Control Statements

Execution of an image control statement divides the execution sequence on an image into segments. The following are image control statements:

- The SYNC ALL statement
- The SYNC IMAGES statement
- The SYNC MEMORY statement
- An ALLOCATE or DEALLOCATE statement that has a coarray allocatable object
- The CRITICAL or END CRITICAL statement
- The EVENT POST or EVENT WAIT statement
- The LOCK or UNLOCK statement
- Any statement that completes execution of a block or procedure and which results in the implicit deallocation of a coarray
- A CALL statement that references the intrinsic subroutine MOVE_ALLOC with coarray arguments
- The STOP statement
- The END statement of a main program

A SYNC MEMORY statement is executed for all image control statements except CRITICAL, END CRITICAL, EVENT POST, EVENT WAIT, LOCK, and UNLOCK.

During an execution of a statement that invokes more than one procedure, at most one invocation can cause execution of an image control statement other than CRITICAL or END CRITICAL.

NOTE
Collective actions may hang if images have stopped or failed and the other images have not all detected the stop or fail; for more information, see FAILED_IMAGES.

STAT= and ERRMSG= Specifiers in Image Control Statements

If the STAT= specifier appears in an image control statement, successful execution of the statement causes the specified variable to become defined with the value zero. In a given image control statement, the *stat-var* in a STAT= specifier, the *err-var* in an ERRMSG= specifier, the *log-var* in an ACQUIRED_LOCK= specifier, and an event variable or lock variable must not depend on one another.

If the STAT= specifier appears in an EVENT WAIT or a SYNC MEMORY statement and an error occurs, *stat-var* is defined with a processor-dependent positive value that is different from the value of STAT_STOPPED_IMAGE or STAT_FAILED_IMAGE.

The images involved in the execution of a SYNC ALL statement are the images of the current team. The images involved in the execution of a SYNC IMAGES statement are the specified images and the image executing the SYNC IMAGES statement. The images involved in the execution of an EVENT POST statement are the image executing the statement and the image on which the event variable is located.

If the STAT= specifier appears in an EVENT POST, SYNC ALL, or SYNC IMAGES statement and execution of one of these statements involves synchronization with an image that has initiated normal termination, the variable becomes defined with the value of the constant STAT_STOPPED_IMAGE in the intrinsic module ISO_FORTRAN_ENV. Otherwise, if no other error condition occurs and one of the involved images has failed, the STAT= specifier becomes defined with the value STAT_FAILED_IMAGE in the intrinsic module ISO_FORTRAN_ENV. If any other error condition occurs during execution of one of these statements, the variable becomes defined with a processor-dependent positive integer value that is different from the value of STAT_STOPPED_IMAGE or STAT_FAILED_IMAGE.

If the STAT= specifier appears in a SYNC ALL or SYNC IMAGES statement and the error STAT_STOPPED_IMAGES occurs, the effect of executing the statement is the same as that of executing the SYNC_MEMORY statement.

If the STAT= specifier appears in a LOCK statement and the lock variable is located on an image that has failed, the specified variable becomes defined with the value STAT_FAILED_IMAGE. If the lock variable is locked by the executing image, the specified variable becomes defined with the value of STAT_LOCKED. Otherwise, if the lock variable is unlocked because the image that locked it has failed, the specified STAT= variable becomes defined with the value STAT_UNLOCKED_FAILED_IMAGE defined in the intrinsic module ISO_FORTRAN_ENV.

If the STAT= specifier appears in an UNLOCK statement and the lock variable is located on an image that has failed, the specifier becomes defined with the value STAT_FAILED_IMAGE. Otherwise, if the lock variable has the value unlocked, the variable specified by the STAT= specifier becomes defined with the value of STAT_UNLOCKED. If the STAT= specifier appears in an UNLOCK statement and the lock variable is locked by a different image, the specified variable becomes defined with the value STAT_LOCKED_OTHER_IMAGE. The named constants STAT_LOCKED, STAT_UNLOCKED, and STAT_LOCKED_OTHER_IMAGE are defined in the intrinsic module ISO_FORTRAN_ENV.

If any other error condition occurs during execution of a LOCK or UNLOCK statement, the specified variable becomes defined with a positive integer value that is different from STAT_LOCKED, STAT_UNLOCKED, STAT_UNLOCKED_FAILED_IMAGE, and STAT_LOCKED_OTHER_IMAGE.

If an image completes execution of a CRITICAL statement that has a STAT= specifier and the previous image that entered the CRITICAL construct failed during execution of the construct, the specifier becomes defined with the value STAT_FAILED_IMAGE and the execution of the construct executes normally. If any other error occurs during execution of the construct, the specifier becomes defined with a positive integer value other different from STAT_FAILED_IMAGE.

If an error condition occurs during execution of an image control statement that does not contain the STAT= specifier, error termination is initiated.

If an ERRMSG= specifier appears in an image control statement, and an error condition occurs during execution of that statement, the processor will assign an explanatory message to the specified variable. If no such condition occurs, the processor will not change the value or definition status of the variable.

The set of error conditions that can occur during execution of an image control statement is processor dependent.

ISO_FORTRAN_ENV Module

Execution Segments for Images

On each image, a segment is the sequence of statements executed before the first execution of an image control statement, between the execution of two image control statements, or after the last execution of an image control statement.

The segment executed immediately before the execution of an image control statement includes the evaluation of all expressions within that image control statement.

A coarray can be referenced or defined by execution of an atomic subroutine during the execution of a segment that is unordered, relative to the execution of a segment in which the coarray is referenced or defined by execution of an atomic subroutine. An event variable can be referenced or defined during the execution of a segment that is unordered relative to the execution of another segment in which that event variable is defined. Otherwise, the following rules apply:

- If a variable is defined on an image in a segment, it must not be referenced, defined, or become undefined in a segment on another image unless the segments are ordered.
- If the allocation of an allocatable subobject of a coarray or the pointer association of a pointer subobject of a coarray is changed on an image in a segment, that subobject must not be referenced or defined in a segment on another image unless the segments are ordered.
- If a procedure invocation on image P is in execution in segments Pi, Pi+1, ..., Pk and defines a noncoarray dummy argument, the effective argument must not be referenced, defined, or become undefined on another image Q in a segment Qj unless Qj precedes Pi or succeeds Pk (because a copy of the actual argument may be passed to the procedure)

Incorrect sequencing of image control statements can suspend execution indefinitely. For example, one image might be executing a SYNC ALL statement while another is executing an ALLOCATE statement for a coarray.

Image Control Statements

Program Units and Procedures

A Fortran program consists of one or more program units. There are four types of program units:

- Main program

  The program unit that denotes the beginning of execution. It may or may not have a PROGRAM statement as its first statement.
- External procedures

  Program units that are either user-written functions or subroutines.
- Modules and submodules

  Program units that contain declarations, type definitions, procedures, or interfaces that can be shared by other program units. A module can be extended by one or more program units called submodules. A submodule can in turn be extended by one or more submodules.
- Block data program units

  Program units that provide initial values for variables in named common blocks.

A program unit does not have to contain executable statements; for example, it can be a module containing interface blocks for subroutines.

A procedure can be invoked during program execution to perform a specific task. It specifies the EXTERNAL attribute for all procedure entities in the procedure declaration list. A procedure declaration is denoted by a PROCEDURE statement.

There are several kinds of procedures, as follows:

Kind of Procedure	Description
External Procedure	A procedure that is not part of any other program unit.
Module Procedure	A procedure defined within a module.
Internal Procedure[1]	A procedure (other than a statement function) contained within a main program, function, or subroutine.
Intrinsic Procedure	A procedure defined by the Fortran language.
Dummy Procedure	A dummy argument specified as a procedure or appearing in a procedure reference. A dummy procedure with the POINTER attribute is a dummy procedure pointer.
Procedure Pointer	A procedure that has the EXTERNAL and POINTER attributes. It may be pointer associated with an external procedure, a module procedure, an intrinsic procedure, or a dummy procedure that is not a procedure pointer.
Statement function	A computing procedure defined by a single statement.

Kind of Procedure	Description

[1] The program unit that contains an internal procedure is called its *host*.

A *function* is invoked in an expression using the name of the function or a defined operator. It returns a a single value (function result) that is used to evaluate the expression.

A *subroutine* is invoked in a CALL statement or by a defined assignment statement. It does not directly return a value, but values can be passed back to the calling program unit through arguments (or variables) known to the calling program.

Recursion (direct or indirect) is permitted for functions and subroutines.

A procedure interface refers to the properties of a procedure that interact with or are of concern to the calling program. A procedure interface can be explicitly defined in interface blocks. All program units, except block data program units, can contain interface blocks.

Scope
RECURSIVE keyword

Main Program

A main program is a program unit whose first statement is not a SUBROUTINE, FUNCTION, MODULE, SUBMODULE, or BLOCK DATA statement. Program execution always begins with the first executable statement in the main program, so there must be exactly one main program unit in every executable program. For more information, see PROGRAM.

Procedure Characteristics

The characteristics of a procedure are as follows:

- Whether it is classified as a function or subroutine
- The characteristics of its result value if it is a function
- The characteristics of its dummy arguments
- Whether it is pure
- Whether it is impure
- Whether it is elemental
- Whether it has the BIND attribute

Characteristics of Dummy Arguments

Each dummy argument has the characteristic that it is a dummy data object, a dummy procedure, or an asterisk indicating an alternate return indicator.

The characteristics of a dummy data object are as follows:

- Its type and type parameters (if any)
- Its shape
- Its intent
- Its corank
- Its codimensions
- Whether it is optional
- Whether it is allocatable
- Whether it has the ASYNCHRONOUS, CONTIGUOUS, VALUE, or VOLATILE attribute

- Whether it is a pointer or a target
- Whether it is polymorphic
- Whether or not it is assumed rank or assumed type

If a type parameter of an object or a bound of an array is not a constant expression, a characteristic is the exact dependence on the entities in the expression. Another characteristic is whether a shape, size, or type parameter is assumed or deferred.

The characteristics of a dummy procedure are as follows:

- Whether it is optional
- The explicitness of its interface
- Its characteristics as a procedure if the interface is explicit
- Whether it is a pointer

Characteristics of Function Results

The characteristics of a function result are as follows:

- Its type, type parameters (if any), and rank
- Whether it is allocatable
- Whether it has the CONTIGUOUS attribute
- Whether it is a pointer
- Whether it is a procedure pointer
- Whether it is polymorphic

If a function result is an array that is not allocatable or a pointer, a characteristic is its shape.

If a type parameter of a function result or a bound of a function result array is not a constant expression, a characteristic is the exact dependence on the entities in the expression.

If type parameters of a function result are deferred, a characteristic is which parameters are deferred. Another characteristic is whether the length of a character function result is assumed.

Modules and Module Procedures

A module program unit contains specifications and definitions that can be made accessible to other program units. There are two types of modules, intrinsic and nonintrinsic. Intrinsic modules are included in the Fortran library; nonintrinsic modules are user-defined.

For the module to be accessible, the other program units must reference its name in a USE statement, and the module entities must be public. This module reference lets the program unit access the public definitions, specifications, and procedures in the module. Entities in a module are public by default, unless the USE statement specifies otherwise or the PRIVATE attribute is specified for the module entities.

A module reference causes use association between the using program unit and the entities in the module.

A submodule extends a module or another submodule. It provides additional structuring facilities for modules. Data objects and procedure pointers declared in a module implicitly have the SAVE attribute.

For more information on module program units, see MODULE. For more information about submodule program units, see SUBMODULE.

A module procedure is a procedure declared and defined in a module, between its CONTAINS and END statements. For more information, see MODULE PROCEDURE.

See Also

PRIVATE attribute
PUBLIC attribute
Use association

Separate Module Procedures

A *separate module procedure* is a module procedure that is declared in a *separate interface body*. To denote separate module procedures, you must specify the keyword MODULE as a prefix in the initial statement of both of the following:

- A separate module procedure body
- A separate interface body

The interface block that contains the separate interface body must be nonabstract.

A separate interface body can be declared in a module or a submodule. The corresponding separate module procedure may be defined (implemented) in the same module or submodule or a descendent of the module or submodule. A separate module procedure can only be defined once.

Usually, the separate interface body is specified in a module and the separate module procedure is defined in a descendent submodule.

In the following example, FOO is a separate module procedure whose interface is specified in module M while the procedure body is defined in submodule A:

```
module M
  type tt
    real r
  end type tt

  interface
    real module function FOO (arg)
      type(tt), intent(in) :: arg
    end function FOO
  end interface
end module M

submodule (M) A
contains
  real module function FOO (arg) result(res)
     type(tt), intent(in) :: arg
     res = arg%r
  end function FOO
end submodule A
```

A separate module procedure is accessible by use association only if its interface body is declared in a module and it is public (for example, FOO in the above example). If a separate module interface is declared in a submodule, the module procedure is only accessible in that submodule or its descendent submodules.

A separate module procedure interface body (either in a module or submodule) has access to entities in its host through host association.

> **NOTE**
> For an interface body that is *not* a separate interface body, IMPORT statements are required to make entities accessible by host association. However, IMPORT statements are not permitted in a separate interface body.

The initial statement of a separate module procedure body can take one of the two following forms:

- MODULE appears as a prefix for a FUNCTION or SUBROUTINE statement

  The following shows an example using this form:

```
submodule (M) A
contains
  real module function foo (arg) result(res)
```

```
    type(tt), intent(in) :: arg
    res = arg%r
  end function foo
end submodule A
```

With this form, a separate module procedure must specify the same characteristics and dummy argument names as its corresponding separate interface body.

They must both be functions or subroutines; they must both be pure or not; they must both be elemental or not. The characteristics of its dummy arguments and the characteristics of the function result must also be the same.

NON_RECURSIVE or RECURSIVE can appear only if NON_RECURSIVE or RECURSIVE appear respectively as a prefix in the corresponding separate interface body.

Note that the restrictions of matching dummy argument names and matching PURE, NON_RECURSIVE, and RECURSIVE specifications only apply to separate module procedures. For an external procedure, the procedure definition and its interface body can differ with regard to dummy argument names, to whether it is pure, and to whether or not it is recursive.

A procedure defined in a submodule with the BIND attribute cannot have a binding label (that is, BIND(C, NAME="a-binding-label") unless it is a separate module procedure and its interface is declared in the ancestor module. The binding label specified in a separate module procedure definition must match the binding label specified in the separate interface body.

For this form, the result variable name for a function is determined by the FUNCTION statement in the module subprogram. The result variable name in the interface is ignored.

- MODULE PROCEDURE statement

  This has the following form:

```
MODULE PROCEDURE procedure-name
  [specification-part]
  [execution-part]
  [internal-subprogram-part]
END [PROCEDURE [procedure-name]]
```

  The following shows an example using this form:

```
submodule (M) A
contains
  module procedure foo
     foo = arg%r
  end procedure foo
end submodule A
```

  This syntax avoids the redeclaration of the function or subroutine in the separate module procedure definition and just takes the characteristics, dummy argument names, and the function result variable name from the separate interface body.

A separate module procedure does not have to be defined. The separate module procedure interface can be used to specify an explicit interface; however, the procedure must not be called.

> **NOTE**
> Two modules cannot have USE statements that reference each other because circular reference is not allowed. However, you can solve that problem by putting at least one side of the USEs in submodules. This is because submodules cannot be referenced by use association and the USE statements in submodules are effectively hidden.

Examples

See the examples in SUBMODULE.

SUBMODULE

Intrinsic Modules

Intrinsic modules, like other module program units, contain specifications and definitions that can be made accessible to other program units. The intrinsic modules are part of the Fortran library.

An intrinsic module is specified in a USE statement, as follows:

`USE, INTRINSIC :: mod-name [, rename-list] ...`

`USE, INTRINSIC :: mod-name, ONLY : [, only-list]`

mod-name	Is the name of the intrinsic module.
rename-list	See the description in USE.
only-list	See the description in USE.

Procedures and types defined in an intrinsic module are not themselves intrinsic.

An intrinsic module can have the same name as other global entities, such as program units, common blocks, or external procedures. A scoping unit must not access both an intrinsic module and a non-intrinsic module with the same name.

When INTRINSIC is used, *mod-name* must be the name of an intrinsic module. If NON_INTRINSIC is used, *mod-name* must be the name of an nonintrinsic module. If neither is specified, *mod-name* must be the name of an intrinsic or nonintrinsic module. If both are provided, the nonintrinsic module is used.

The following intrinsic modules are included in the Fortran library: ISO_C_BINDING, ISO_FORTRAN_ENV, and IEEE Intrinsic Modules.

ISO_C_BINDING Module

The ISO_C_BINDING intrinsic module provides access to data entities that are useful in mixed-language programming. It takes the following form:

`USE, INTRINSIC :: ISO_C_BINDING`

This intrinsic module provides access to the following data entities:

- Named Constants
- Derived Types

  Derived type C_PTR is interoperable with any C object pointer type. Derived type C_FUNPTR is interoperable with any C function pointer type.
- Intrinsic Module Procedures

Standard Tools for Interoperabillity

Named Constants in the ISO_C_BINDING Module

The ISO_C_BINDING named constants represent kind type parameters of data representations compatible with C types.

Intrinsic-Type Constants

The following table shows interoperable Fortran types and C Types.

Fortran Type	Named Constant for the KIND	C Type
INTEGER	C_INT	int
	C_SHORT	short int
	C_LONG	long int
	C_LONG_LONG	long long int
	C_SIGNED_CHAR	signed char, unsigned char
	C_SIZE_T	size_t
	C_INT8_T	int8_t
	C_INT16_T	int16_t
	C_INT32_T	int32_t
	C_INT64_T	int64_t
	C_INT_LEAST8_T	int_least8_t
	C_INT_LEAST16_T	int_least16_t
	C_INT_LEAST32_T	int_least32_t
	C_INT_LEAST64_T	int_least64_t
	C_INT_FAST8_T	int_fast8_t
	C_INT_FAST16_T	int_fast16_t
	C_INT_FAST32_T	int_fast32_t
	C_INT_FAST64_T	int_fast64_t
	C_INTMAX_T	intmax_t
	C_INTPTR_T	intptr_t
	C_PTRDIFF_T	ptrdiff_t
REAL	C_FLOAT	float
	C_DOUBLE	double
	C_LONG_DOUBLE	long double
COMPLEX	C_FLOAT_COMPLEX	float _Complex
	C_DOUBLE_COMPLEX	double _Complex
	C_LONG_DOUBLE_COMPLEX	long double _Complex
LOGICAL[1]	C_BOOL	_Bool
CHARACTER[2]	C_CHAR	char

[1] Use compiler option `fpscomp logicals` so that .TRUE. is 1 and .FALSE. is 0 as defined for C's _Bool.

Fortran Type	Named Constant for the KIND	C Type
[2]For character type, the length type parameter must be omitted or it must be specified by a constant expression whose value is one.		

For example, an integer type with the kind type parameter C_LONG is interoperable with the C integer type "long" or any C type derived from "long".

The value of C_INT will be a valid value for an integer kind type parameter on the processor. The values for the other integer named constants (C_INT*) will be a valid value for an integer kind type parameter on the processor, if any, or one of the following:

- -1 if the C processor defines the corresponding C type and there is no interoperating Fortran processor kind
- -2 if the C processor does not define the corresponding C type

The values of C_FLOAT, C_DOUBLE, and C_LONGDOUBLE will be a valid value for a real kind type parameter on the processor, if any, or one of the following:

- -1 if the C processor's type does not have a precision equal to the precision of any of the Fortran processor's real kinds
- -2 if the C processor's type does not have a range equal to the range of any of the Fortran processor's real kinds
- -3 if the C processor's type has neither the precision or range equal to the precision or range of any of the Fortran processor's real kinds
- -4 if there is no interoperating Fortran processor or kind for other reasons

The values of C_FLOAT_COMPLEX, C_DOUBLE_COMPLEX, and C_LONG_DOUBLE_COMPLEX will be the same as those of C_FLOAT, C_DOUBLE, and C_LONG_DOUBLE, respectively.

The value of C_BOOL will be a valid value for a logical kind parameter on the processor, if any, or -1.

The value of C_CHAR is the character kind.

Character Constants

The following table shows interoperable named constants and C characters:

Fortran Named Constant	Definition	C Character
C_NULL_CHAR	null character	'\0'
C_ALERT	alert	'\a'
C_BACKSPACE	backspace	'\b'
C_FORM_FEED	form feed	'\f'
C_NEW_LINE	new line	'\n'
C_CARRIAGE_RETURN	carriage return	'\r'
C_HORIZONTAL_TAB	horizontal tab	'\t'
C_VERTICAL_TAB	vertical tab	'\v'

Derived-Type Constants

The constant C_NULL_PTR is of type C_PTR; it has the value of a C null data pointer. The constant C_NULL_FUNPTR is of type C_FUNPTR; it has the value of a C null function pointer.

Intrinsic Module Procedures - ISO_C_BINDING

The following procedures are provided with the ISO_C_BINDING intrinsic module:

- C_ASSOCIATED
- C_F_POINTER
- C_F_PROCPOINTER
- C_FUNLOC
- C_LOC
- C_SIZEOF

C_F_POINTER and C_F_PROCPOINTER are impure, the other procedures are pure.

ISO_FORTRAN_ENV Module

The ISO_FORTRAN_ENV intrinsic module provides information about the Fortran run-time environment. It takes the following form:

```
USE, INTRINSIC :: ISO_FORTRAN_ENV
```

This intrinsic module provides access to the following data entities:

- Named Constants
- Derived Types
- Intrinsic Module Procedures

Named Constants in the ISO_FORTRAN_ENV Module

The ISO_FORTRAN_ENV intrinsic module provides the following named constants that you can use to get information on the Fortran environment. They are all scalars of type default integer.

Named Constant	Definition
ATOMIC_INT_KIND	Is the kind type parameter used when defining integer variables used in atomic operations.
ATOMIC_LOGICAL_KIND	Is the kind type parameter used when defining logical variables used in atomic operations.
CHARACTER_KINDS	Is the kind type parameter supported by the processor that is used when defining variables of type character. This is a default integer array constant. The rank of the array is one, its lower bound is one, and its size is the number of character kinds supported. In Intel® Fortran, its value is [1].
CHARACTER_STORAGE_SIZE	Is the size of the character storage unit expressed in bits.
ERROR_UNIT	Identifies the preconnected external unit used for error reporting.
FILE_STORAGE_SIZE	Is the size of the file storage unit expressed in bits. To use this constant, compiler option assume byterecl must be enabled.
INPUT_UNIT	Identifies the preconnected external unit as the one specified by an asterisk in a READ statement. To use this constant, compiler option assume noold_unit_star must be enabled.

Named Constant	Definition
INT8 INT16 INT32 INT64	Are the kind type parameters that specify an INTEGER type whose storage size is 8 bits, 16 bits, 32 bits, and 64 bits, respectively. If, for any of these constants, the processor supports more than one kind of that size, the kind value is determined by the processor. If the processor supports no kind of a particular size, that constant is equal to -2 if the processor supports a kind with larger size; otherwise, -1. In Intel Fortran, their respective values are 1, 2, 4, and 8.
INTEGER_KINDS	Is the kind type parameter supported by the processor that is used when defining variables of type integer. This is a default integer array constant. The rank of the array is one, its lower bound is one, and its size is the number of integer kinds supported. In Intel Fortran its value is [1, 2, 4, 8].
IOSTAT_END	Is the value assigned to the variable specified in an IOSTAT= specifier if an end-of-file condition occurs during execution of an input/output statement and no error condition occurs.
IOSTAT_EOR	Is the value assigned to the variable specified in an IOSTAT= specifier if an end-of-record condition occurs during execution of an input/output statement and no error condition occurs.
IOSTAT_INQUIRE_INTERNAL_UNIT	Is the value assigned to the variable specified in an IOSTAT= specifier in an INQUIRE statement if the unit number identifies an internal unit. This is a negative value, indicating an error condition.
LOGICAL_KINDS	Is the kind type parameter supported by the processor that is used when defining variables of type logical. This is a default integer array constant. The rank of the array is one, its lower bound is one, and its size is the number of logical kinds supported. In Intel® Fortran its value is [1, 2, 4, 8].
NUMERIC_STORAGE_SIZE	Is the size of the numeric storage unit expressed in bits.
OUTPUT_UNIT	Identifies the preconnected external unit as the one specified by an asterisk in a WRITE statement. To use this constant, compiler option assume noold_unit_star must be enabled.
REAL_KINDS	Is the kind type parameter supported by the processor that is used when defining variables of type real. This is a default integer array constant. The rank of the array is one, its lower bound is one, and its size is the number of real kinds supported. In Intel Fortran its value is [4, 8, 16].
REAL32 REAL64 REAL128	Are the kind type parameters that specify a real type whose storage size is 32 bits, 64 bits, and 128 bits, respectively. If, for any of these constants, the processor supports more than one kind of that size,

Named Constant	Definition
	the kind value is determined by the processor. If the processor supports no kind of a particular size, that constant is equal to -2 if the processor supports kinds of a larger size; otherwise, -1. In Intel Fortran, their respective values are 4, 8, and 16.
STAT_FAILED_IMAGE	The value assigned to the variable specified in a STAT= specifier of an image control statement or coindexed object reference, or the STAT argument of a collective or atomic subroutine if an image involved in the execution of that statement, reference, or subroutine has failed.
STAT_LOCKED	The value assigned to the variable specified in a STAT= specifier of a LOCK statement if the lock variable is locked by the executing image.
STAT_LOCKED_OTHER_IMAGE	The value assigned to the variable specified in a STAT= specifier of an UNLOCK statement if the lock variable is locked by another image.
STAT_STOPPED_IMAGE	The value assigned to the variable specified in a STAT= specifier of a statement if execution of the statement requires synchronization with an image that has initiated normal termination (an image control statement). It is the value assigned to the STAT variable of a collective subroutine if the current team contains images that inititiated normal termination.
STAT_UNLOCKED	The value assigned to the variable specified in a STAT= specifier of an UNLOCK statement if the lock variable is unlocked.
STAT_UNLOCKED_FAILED_IMAGE	The value assigned to the STAT= specifier of a LOCK statement if the lock variable is unlocked because the image that locked it has failed.

Derived Types in the ISO_FORTRAN_ENV Module

The ISO_FORTRAN_ENV intrinsic module provides the following predefined derived types.

EVENT_TYPE	This is a derived type with private components. It is an extensible type with no type parameters. Each component that is nonallocatable is initialized by default. A scalar variable of type EVENT_TYPE is an event variable. The value of an event variable contains its event count, which is modified by a sequence of EVENT POST and EVENT WAIT statements. A modification to the event count is as if the intrinsic ATOMIC_ADD were executed with a variable that stores the count as its ATOM argument. A coarray that is of type EVENT_TYPE can be referenced or defined during execution of a segment that is unordered relative to the execution of another segment in which that coarray is

	defined. The event count is an integer of ATOMIC_INT_KIND. The initial value of the event count of a variable of type EVENT_TYPE is zero. A named entity with declared type EVENT_TYPE, or which has a noncoarray potential subobject component with declared type EVENT_TYPE, must be a variable. A component with type EVENT_TYPE must be a data component. A named variable with declared type EVENT_TYPE must be a coarray. A named variable with a noncoarray potential subobject component of type EVENT TYPE must be a coarray. An event variable must not appear in a variable-definition context except as the *event-var* argument in an EVENT POST or EVENT WAIT statement, as an allocatable object, or as an actual argument in a reference to a procedure with an explicit interface if the corresponding dummy argument has INTENT(INOUT). A variable with a nonpointer subobject of type EVENT_TYPE must not appear in a variable-definition context except as an allocatable object in an ALLOCATE statement without a SOURCE= specifier, as an allocatable object in a DEALLOCATE statement, or as an actual argument in a reference to a procedure with an explicit interface if the corresponding dummy argument has INTENT(INOUT). If EXTENDS appears in a TYPE statement and the type being defined has a potential subobject component of type EVENT_TYPE, its parent type must be EVENT_TYPE or LOCK_TYPE, or have a potential subobject component of type EVENT_TYPE or LOCK_TYPE.
LOCK_TYPE	This is a derived type with private components; none of the components can be allocatable or a pointer. It is an extensible type with no type parameters. It does not have the BIND (C) attribute or type parameters, and is not a sequence type. All components have default initialization. A scalar variable of type LOCK_TYPE is a lock variable. A lock variable can have one of two states: locked or unlocked. The unlocked state is represented by the one value that is the initial value of a LOCK_TYPE variable. The locked state is represented by all other values. The value of a lock variable can be changed with the LOCK and UNLOCK statements. A named variable of type LOCK_TYPE must be a coarray. A named variable with a noncoarray sub-component of type LOCK_TYPE must also be a coarray. A named constant can not be of type LOCK_TYPE, nor can it have a noncoarrray potential subobject component with a declared LOCK_TYPE.

	If EXTENDS appears in TYPE statement and the type being defined has a potential subobject component of type LOCK_TYPE, its parent type must be EVENT_TYPE or LOCK_TYPE, or have a potential subobject component of type EVENT_TYPE or LOCK_TYPE. A lock variable must not appear in a variable definition context except as the lock-variable in a LOCK or UNLOCK statement, as an allocatable object, or as an actual argument in a reference to a procedure with an explicit interface where the corresponding dummy argument has INTENT (INOUT). A variable with a subobject of type LOCK_TYPE must not appear in a variable definition context except as an allocatable object or as an actual argument in a reference to a procedure with an explicit interface where the corresponding dummy argument has INTENT (INOUT).

Intrinsic Module Procedures - ISO_FORTRAN_ENV

The following procedures are provided with the ISO_FORTRAN_ENV intrinsic module:

- COMPILER_OPTIONS
- COMPILER_VERSION

IEEE Intrinsic Modules and Procedures

Intel® Fortran includes IEEE intrinsic modules that support IEEE arithmetic and exception handling. The modules contain derived data types that include named constants for controlling the level of support, and intrinsic module procedures.

To include an IEEE module in your program, specify the intrinsic module name in a USE statement; for example:

```
USE,INTRINSIC :: IEEE_ARITHMETIC
```

You must include the INTRINSIC attribute or the processor will look for a non-intrinsic module. Once you include a module, all related intrinsic procedures are defined.

The following three IEEE intrinsic modules are described in this section:

- IEEE_ARITHMETIC
- IEEE_EXCEPTIONS
- IEEE_FEATURES

Determining Availability of IEEE Features

Before using a particular IEEE feature, you can determine whether your processor supports it by using the IEEE inquiry functions (listed in below section Restrictions for IEEE Intrinsic Procedures).

For example:

- To determine whether IEEE arithmetic is available for a particular kind of real, use intrinsic module function IEEE_SUPPORT_DATATYPE.
- To determine whether you can change a rounding mode, use intrinsic module function IEEE_SUPPORT_ROUNDING.
- To determine whether a divide operation will be supported with the accuracy specified by the IEEE standard, use intrinsic module function IEEE_SUPPORT_DIVIDE.

- To determine whether you can control halting after an exception has occurred, use intrinsic module function IEEE_SUPPORT_HALTING.
- To determine which exceptions are supported in a scoping unit, use intrinsic module function IEEE_SUPPORT_FLAG.
- To determine whether all IEEE features are supported, use intrinsic module function IEEE_SUPPORT_STANDARD.

The compiler establishes the initial IEEE floating-point environment. The user can affect this initial environment with several different command-line options. For the IEEE intrinsic module procedures to work as defined by the Fortran Standard, the following command lines options must be set as follows:

- Option `/fpe:3` (Windows*) or `-fpe3` (Linux* and macOS*) must be set to disable all floating-point exceptions.
- Option `/Qftz-` (Windows*) or `-no-ftz` (Linux* and macOS*) must be set to disable flushing subnormal results to zero (notice that all optimization levels, except `O0`, set `ftz` so the user has to explicitly set "no ftz").
- Option `/fp:precise` (Windows*) or option `-fp-model precise` (Linux* and macOS*) must be set to disable floating-point exception semantics.

Restrictions for IEEE Intrinsic Procedures

The following intrinsic procedures can only be invoked if IEEE_SUPPORT_DATATYPE is true for their arguments of type REAL:

IEEE_CLASS	IEEE_REM
IEEE_COPY_SIGN	IEEE_RINT
IEEE_FMA	IEEE_SCALB
IEEE_IS_FINITE	IEEE_SET_ROUNDING_MODE [3]
IEEE_NEGATIVE	IEEE_SIGNALING_EQ
IEEE_INT	IEEE_SIGNALING_GE
IEEE_IS_NORMAL	IEEE_SIGNALING_GT
IEEE_LOGB	IEEE_SIGNALING_LE
IEEE_MAX_NUM	IEEE_SIGNALING_LT
IEEE_MAX_NUM_MAG	IEEE_SIGNALING_NE
IEEE_MIN_NUM	IEEE_SIGNBIT
IEEE_MIN_NUM_MAG	IEEE_SUPPORT_DENORMAL
IEEE_NEXT_AFTER	IEEE_SUPPORT_DIVIDE
IEEE_NEXT_DOWN [1]	IEEE_SUPPORT_INF
IEEE_NEXT_UP [1]	IEEE_SUPPORT_IO
IEEE_QUIET_EQ	IEEE_SUPPORT_NAN
IEEE_QUIET_GE	IEEE_SUPPORT_ROUNDING
IEEE_QUIET_GT	IEEE_SUPPORT_SQRT
IEEE_QUIET_LE	IEEE_SUPPORT_SUBNORMAL

IEEE_QUIET_LT	IEEE_SUPPORT_UNORDERED
IEEE_QUIET_NE	IEEE_SUPPORT_VALUE
IEEE_REAL [2]	IEEE_VALUE

[1] IEEE_SUPPORT_INF() must be true if IEEE_NEXT_DOWN is called with the argument -HUGE (X) or if IEEE_NEXT_UP is called with the argument HUGE (X).

[2] IEEE_SUPPORT_DATATYPE (IEEE_REAL (A, KIND)) must also be true.

[3] IEEE_SUPPORT_ROUNDING(ROUND_VALUE, X) must also be true.

For example, the IEEE_IS_NORMAL(X) function can only be invoked if IEEE_SUPPORT_DATATYPE(X) has the value true. Consider the following:

```
USE, INTRINSIC :: IEEE_ARITHMETIC
...
  IF IEEE_SUPPORT_DATATYPE(X) THEN
    IF IEEE_IS_NORMAL(X) THEN
      PRINT *, ' X is a "normal" '
    ELSE
      PRINT *, ' X is not "normal" '
    ENDIF
  ELSE
    PRINT *, ' X is not a supported IEEE type '
  ENDIF
...
```

Certain other IEEE intrinsic module procedures have similar restrictions:

- IEEE_IS_NAN(X) can only be invoked if IEEE_SUPPORT_NAN(X) has the value true.
- IEEE_SET_HALTING_MODE(FLAG, HALTING) can only be invoked if IEEE_SUPPORT_HALTING(FLAG) has the value true.
- IEEE_GET_UNDERFLOW_MODE(GRADUAL) can only be invoked if IEEE_SUPPORT_UNDERFLOW_CONTROL(X) is true for some X.

For intrinsic module function IEEE_CLASS(X), some of the possible return values also have restrictions. These restrictions are also true for argument CLASS in intrinsic module function IEEE_VALUE(X, CLASS):

- IEEE_POSITIVE_INF and IEEE_NEGATIVE_INF can only be returned if IEEE_SUPPORT_INF(X) has the value true.
- IEEE_POSITIVE_DENORMAL, IEEE_POSITIVE_SUBNORMAL, IEEE_NEGATIVE_SUBNORMAL, and IEEE_NEGATIVE_DENORMAL can only be returned if IEEE_SUPPORT_DENORMAL(X) and IEEE_SUPPORT_SUBNORMAL(X) have the value true.
- IEEE_SIGNALING_NAN and IEEE_QUIET_NAN can only be returned if IEEE_SUPPORT_NAN(X) has the value true.

IEEE_ARITHMETIC Intrinsic Module

The IEEE_ARITHMETIC module contains derived data types that include named constants for controlling the level of support, and intrinsic module procedures.

The derived types in the intrinsic modules have components that are private. The IEEE_ARITHMETIC intrinsic module supports IEEE arithmetic and features. It defines the following derived types:

- IEEE_CLASS_TYPE: Identifies a class of floating-point values. Its values are the following named constants:

IEEE_SIGNALING_NAN	IEEE_NEGATIVE_NORMAL
IEEE_QUIET_NAN	IEEE_POSITIVE_DENORMAL
IEEE_POSITIVE_INF	IEEE_NEGATIVE_DENORMAL

IEEE_NEGATIVE_INF	IEEE_POSITIVE_ZERO
IEEE_POSITIVE_NORMAL	IEEE_NEGATIVE_ZERO
IEEE_OTHER_VALUE	

- IEEE_ROUND_TYPE: Identifies a rounding mode. Its values are the following named constants:

IEEE_AWAY [1]	IEEE_OTHER [4]
IEEE_DOWN [2]	IEEE_TO_ZERO [5]
IEEE_NEAREST [3]	IEEE_UP [6]

[1] Corresponds to ISO/IEC/IEEE 60559:2011 rounding attribute `roundTiesToAway`. Intel hardware does not support this mode.

[2] Corresponds to ISO/IEC/IEEE 60559:2011 rounding attribute `roundTowardNegative`.

[3] Corresponds to ISO/IEC/IEEE 60559:2011 rounding attribute `roundTiesToEven`.

[4] Specifies the rounding mode does not conform to the IEEE standard.

[5] Corresponds to ISO/IEC/IEEE 60559:2011 rounding attribute `roundTowardZero`.

[6] Corresponds to ISO/IEC/IEEE 60559:2011 rounding attribute `roundTowardPositive`.

The IEEE_ARITHMETIC intrinsic module also defines the following operators:

- Elemental operator = = for two values of one of the above types to return true if the values are the same; otherwise, false.
- Elemental operator /= for two values of one of the above types to return true if the values differ; otherwise, false.

The IEEE_ARITHMETIC module includes support for IEEE_EXCEPTIONS module, and public entities in IEEE_EXCEPTIONS module are also public in the IEEE_ARITHMETIC module.

To see a summary of all the IEEE_ARITHMETIC intrinsic procedures, see IEEE Intrinsic Modules Quick Reference Tables

IEEE_EXCEPTIONS Intrinsic Module

The IEEE_EXCEPTIONS module contains derived data types that include named constants for controlling the level of support, and intrinsic module procedures.

The derived types in the intrinsic modules have components that are private. The IEEE_EXCEPTIONS intrinsic module supports the setting, clearing, saving, restoring, or testing of exception flags. It defines the following derived types:

- IEEE_FLAG_TYPE: Identifies an exception flag for errors that occur during an IEEE arithmetic operation or assignment. Its values are the following named constants:

IEEE_INVALID	IEEE_DIVIDE_BY_ZERO
IEEE_OVERFLOW	IEEE_INEXACT
IEEE_UNDERFLOW	

  Each of the above exceptions has a flag whose value is either quiet or signaling. The initial value is quiet and it signals when the associated exception occurs. To determine the value of a flag, use intrinsic module subroutine IEEE_GET_FLAG. To change the status for a flag, use intrinsic module subroutine IEEE_SET_FLAG or IEEE_SET_STATUS.

  If a flag is signaling on entry to a procedure, the processor sets it to quiet on entry and restores it to signaling on return.

  If a flag is quiet on entry to a procedure with access to modules IEEE_ARITHMETIC or IEEE_EXCEPTIONS, and is signaling on return, the processor will not restore it to quiet.

  The IEEE_FLAG_TYPE module also defines the following named array constants:

  - IEEE_USUAL=(/IEEE_OVERFLOW,IEEE_DIVIDE_BY_ZERO, IEEE_INVALID/)
  - IEEE_ALL=(/IEEE_USUAL,IEEE_UNDERFLOW,IEEE_INEXACT/)
- IEEE_MODES_TYPE: The floating-point modes are the values of the rounding modes, underflow mode, and halting mode. They can be saved in a variable of type IEEE_MODES_TYPE by calling the subroutine IEEE_GET_MODES and restored by calling the subroutine IEEE_SET_MODES.
- IEEE_STATUS_TYPE: The floating-point status can be saved in a variable of type IEEE_STATUS_TYPE by calling the subroutine IEEE_GET_STATUS and restored by calling the subroutine IEEE_SET_STATUS.

The IEEE_ARITHMETIC module includes support for IEEE_EXCEPTIONS module, and public entities in IEEE_EXCEPTIONS module are also public in the IEEE_ARITHMETIC module.

To see a summary of all the IEEE_EXCEPTIONS intrinsic procedures, see IEEE Intrinsic Modules Quick Reference Tables

IEEE_FEATURES Intrinsic Module

The IEEE_FEATURES module contains derived data types that include named constants for controlling the level of support, and intrinsic module procedures.

The derived types in the intrinsic modules have components that are private. The IEEE_FEATURES intrinsic module supports specification of essential IEEE features. It defines the following derived type:

- IEEE_FEATURES_TYPE: Specifies IEEE features. Its values are the following named constants:

IEEE_DATATYPE	IEEE_INF
IEEE_DIVIDE	IEEE_NAN
IEEE_ROUNDING	IEEE_INEXACT_FLAG
IEEE_SQRT	IEEE_INVALID_FLAG
IEEE_SUBNORMAL	IEEE_UNDERFLOW_FLAG
IEEE_HALTING	

IEEE Intrinsic Modules Quick Reference Tables

This topic contains quick reference tables showing categories of IEEE intrinsic modules, a summary of the IEEE_ARITHMETIC intrinsic procedures, and a summary of the IEEE_EXCEPTIONS intrinsic procedures.

Categories of Intrinsic Module Functions

Category	Sub-category	Description
IEEE	Arithmetic	Test IEEE values or provide features: IEEE_CLASS, IEEE_COPY_SIGN, IEEE_FMA, IEEE_INT, IEEE_IS_FINITE, IEEE_IS_NAN, IEEE_IS_NORMAL, IEEE_IS_NEGATIVE, IEEE_LOGB, IEEE_MAX_NUM, IEEE_MAX_NUM_MAG, IEEE_MIN_NUM, IEEE_MIN_NUM_MAG, IEEE_NEXT_AFTER, IEEE_QUIET_EQ, IEEE_QUIET_GE, IEEE_QUIET_GT, IEEE_QUIET_LE, IEEE_QUIET_LT, IEEE_QUIET_NE, IEEE_REAL, IEEE_REM, IEEE_RINT, IEEE_SCALB, IEEE_SIGNALING_EQ, IEEE_SIGNALING_GE, IEEE_SIGNALING_GT, IEEE_SIGNALING LE, IEEE_SIGNALING _LT, IEEE_SIGNALING_NE, IEEE_UNORDERED, IEEE_VALUE, IEEE_NEXT_DOWN, IEEE_NEXT_UP, IEEE_SIGNBIT
	Inquiry	Returns whether the processor supports certain exceptions or IEEE features: IEEE_SUPPORT_DATATYPE, IEEE_SUPPORT_DENORMAL, IEEE_SUPPORT_DIVIDE, IEEE_SUPPORT_INF, IEEE_SUPPORT_IO, IEEE_SUPPORT_NAN,

Category	Sub-category	Description
		IEEE_SUPPORT_SQRT, IEEE_SUPPORT_STANDARD, IEEE_SUPPORT_SUBNORMAL, IEEE_SUPPORT_UNDERFLOW_CONTROL
	Transformational	Returns the kind type parameter of an IEEE value, or whether the processor supports certain IEEE features: IEEE_SELECTED_REAL_KIND, IEEE_SUPPORT_FLAG, IEEE_SUPPORT_HALTING, IEEE_SUPPORT_ROUNDING

Summary of IEEE_ARITHMETIC Procedures

Procedure	Class	Value Returned or Result
IEEE_CLASS (X)	E	The IEEE class
IEEE_COPY_SIGN (X, Y)	E	An argument with a copied sign; the IEEE copysign function
IEEE_FMA (A, B, C)	E	Fused multiply-add
IEEE_GET_ROUNDING_MODE (ROUND_VALUE [, RADIX])	SI	The current IEEE rounding mode
IEEE_GET_UNDERFLOW_MODE (GRADUAL)	SI	The current underflow mode
IEEE_INT (A, ROUND [, KIND])	E	Conversion to INTEGER data type
IEEE_IS_FINITE (X)	E	Whether a value is finite
IEEE_IS_NAN (X)	E	Whether a value is NaN
IEEE_IS_NEGATIVE (X)	E	Whether a value is negative
IEEE_IS_NORMAL (X)	E	Whether a value is normal
IEEE_LOGB (X)	E	An exponent in IEEE floating-point format; the IEEE logb function
IEEE_MAX_NUM (X, Y)	E	The maximum numeric value
IEEE_MAX_NUM_MAG (X, Y)	E	The maximum magnitude numeric value
IEEE_MIN_NUM (X, Y)	E	The minimum numeric value
IEEE_MIN_NUM_MAG (X, Y)	E	The minimum magnitude numeric value
IEEE_NEXT_AFTER (X, Y)	E	The next representable value after X toward Y; the IEEE nextafter function
IEEE_NEXT_DOWN (X)	E	The next lower adjacent machine number
IEEE_NEXT_UP (X)	E	The next higher adjacent machine number
IEEE_QUIET_EQ (A, B)	E	Quiet compare for equality

Procedure	Class	Value Returned or Result
IEEE_QUIET_GE (A, B)	E	Quiet compare for greater than or equal
IEEE_QUIET_GT (A, B)	E	Quiet compare for greater than
IEEE_QUIET_LE (A, B)	E	Quiet compare for less than or equal
IEEE_QUIET_LT (A, B)	E	Quiet compare for less than
IEEE_QUIET_NE (A, B)	E	Quiet compare for inequality
IEEE_REAL (A [, KIND])	E	Conversion to REAL data type
IEEE_REM (X, Y)	E	The result of a remainder operation; the IEEE rem function
IEEE_RINT (X [, ROUND])	E	An integer value rounded according to the current or specified rounding mode
IEEE_SCALB (X, I)	E	The value of X multiplied by 2**I; the IEEE scalb function
IEEE_SELECTED_REAL_KIND ([P] [, R])	T	The kind type parameter for an IEEE real
IEEE_SET_ROUNDING_MODE (ROUND_VALUE [, RADIX])	SI	Sets the IEEE rounding mode
IEEE_SET_UNDERFLOW_MODE (GRADUAL)	SI	Sets the current underflow mode
IEEE_SIGNALING_EQ (A, B)	E	Signaling compare for equality
IEEE_SIGNALING_GE (A, B)	E	Signaling compare for greater than or equal
IEEE_SIGNALING_GT (A, B)	E	Signaling compare for greater than
IEEE_SIGNALING_LE (A, B)	E	Signaling compare for less than or equal
IEEE_SIGNALING_LT (A, B)	E	Signaling compare for less than
IEEE_SIGNALING_NE (A, B)	E	Signaling compare for inequality
IEEE_SIGNBIT (X)	E	Tests the sign bit of X
IEEE_SUPPORT_DATATYPE ([X])	I	Whether IEEE arithmetic is supported
IEEE_SUPPORT_DENORMAL ([X])	I	Whether subnormal numbers are supported
IEEE_SUPPORT_DIVIDE ([X])	I	Whether divide accuracy compares to IEEE standard
IEEE_SUPPORT_INF ([X])	I	Whether IEEE infinities are supported

Procedure	Class	Value Returned or Result
IEEE_SUPPORT_IO ([X])	I	Whether IEEE base conversion rounding is supported during formatted I/O
IEEE_SUPPORT_NAN ([X])	I	Whether IEEE Not-A-Number is supported
IEEE_SUPPORT_ROUNDING (ROUND_VALUE [, X])	T	Whether a particular rounding mode is supported
IEEE_SUPPORT_SQRT ([X])	I	Whether IEEE square root is supported
IEEE_SUPPORT_STANDARD ([X])	I	Whether all IEEE capabilities are supported
IEEE_SUPPORT_SUBNORMAL ([X])	I	Whether subnormal numbers are supported
IEEE_SUPPORT_UNDERFLOW_CONTROL(X)	I	Whether control of underflow mode is supported

Block Data Program Units Overview

A block data program unit provides initial values for nonpointer variables in named common blocks. For more information, see BLOCK DATA.

Examples

An example of a block data program unit follows:

```
BLOCK DATA WORK
   COMMON /WRKCOM/ A, B, C (10,10)
   DATA A /1.0/, B /2.0/, C /100*0.0/
END BLOCK DATA WORK
```

Functions, Subroutines, and Statement Functions

Functions, subroutines, and statement functions are user-written subprograms that perform computing procedures. The computing procedure can be either a series of arithmetic operations or a series of Fortran statements. A single subprogram can perform a computing procedure in several places in a program, to avoid duplicating a series of operations or statements in each place.

The following table shows the statements that define these subprograms, and how control is transferred to the subprogram:

Subprogram	Defining Statements	Control Transfer Method
Function	FUNCTION or ENTRY	Function reference[1]
Subroutine	SUBROUTINE or ENTRY	CALL statement[2]
Statement function	Statement function definition	Function reference

[1] A function can also be invoked by a defined operation (see Defining Generic Operators).

[2] A subroutine can also be invoked by a defined assignment (see Defining Generic Assignment).

A *function reference* is used in an expression to invoke a function; it consists of the function name and its actual arguments. The function reference returns a value to the calling expression that is used to evaluate the expression.

ENTRY statement

CALL statement

General Rules for Function and Subroutine Subprograms

A subprogram can be an external, module, or internal subprogram. The END statement for an internal or module subprogram must be END SUBROUTINE [name] for a subroutine, or END FUNCTION [name] for a function. In an external subprogram, the SUBROUTINE and FUNCTION keywords are optional.

If a subprogram name appears after the END statement, it must be the same as the name specified in the SUBROUTINE or FUNCTION statement.

Function and subroutine subprograms can change the values of their arguments, and the calling program can use the changed values.

A SUBROUTINE or FUNCTION statement can be optionally preceded by an OPTIONS statement.

Dummy arguments (except for dummy pointers or dummy procedures) can be specified with an intent and can be made optional.

Subroutines and functions are by default assumed to be non-recursive. This can be changed by declaring the function RECURSIVE, either with the RECURSIVE keyword on the SUBROUTINE or FUNCTION statement, or by specifying an option on the command line or in an OPTIONS statement. The Fortran 2018 Standard specifies that the default mode of compilation is recursion; prior standards specified non-recursion. The default mode of compilation will change to recursion in a future release.

INTENT attribute

Recursive Procedures

A recursive procedure is a function or subroutine that references itself, either directly or indirectly. For more information, see RECURSIVE.

Pure Procedures

A pure procedure is a procedure that has no side effects. For more information, see PURE.

Impure Procedures

An impure procedure is a user-defined procedure that has side effects. For more information, see IMPURE

Elemental Procedures

An elemental procedure is a user-defined procedure defined on scalar arguments that may be called with array arguments. An elemental procedure is pure unless you specify that it is impure. For more information, see PURE, ELEMENTAL, and IMPURE.

Functions Overview

A *function* subprogram is invoked in an expression and returns a single value (a function result) that is used to evaluate the expression. For more information, see FUNCTION.

RESULT Keyword Overview

If you use the RESULT keyword in a FUNCTION statement, you can specify a local variable name for the function result. For more information, see RESULT.

Function References

Functions are invoked by a function reference in an expression or by a defined operation.

A function reference takes the following form:

fun ([*a-arg* [, *a-arg*] ...])

fun	Is the name of the function subprogram or a procedure pointer.
a-arg	Is an actual argument optionally preceded by [keyword=], where *keyword* is the name of a dummy argument in the explicit interface for the function. The keyword is assigned a value when the procedure is invoked. Each actual argument must be a variable, an expression, or the name of a procedure. (It must not be the name of an internal procedure, statement function, or the generic name of a procedure.)

Description

When a function is referenced, each actual argument is associated with the corresponding dummy argument by its position in the argument list or by the name of its keyword. The arguments must agree in type and kind parameters.

Execution of the function produces a result that is assigned to the function name or to the result name, depending on whether the RESULT keyword was specified.

The program unit uses the result value to complete the evaluation of the expression containing the function reference.

If positional arguments and argument keywords are specified, the argument keywords must appear last in the actual argument list.

If a dummy argument is optional, the actual argument can be omitted.

If a dummy argument is specified with the INTENT attribute, its use may be limited. A dummy argument whose intent is not specified is subject to the limitations of its associated actual argument.

An actual argument associated with a dummy procedure must be the specific name of a procedure, or be another dummy procedure. Certain specific intrinsic function names must not be used as actual arguments (see table Specific Functions Not Allowed as Actual Arguments in Intrinsic Procedures).

Examples

Consider the following example:

```
X = 2.0
NEW_COS = COS(X)        ! A function reference
```

Intrinsic function COS calculates the cosine of 2.0. The value -0.4161468 is returned (in place of COS(X)) and assigned to NEW_COS.

Subroutines Overview

A *subroutine* subprogram is invoked in a CALL statement or by a defined assignment statement, and does not return a particular value. For more information, see SUBROUTINE.

Statement Functions Overview

A statement function is a procedure defined by a single statement in the same program unit in which the procedure is referenced. For more information, see Statement Function.

Entry Points in Subprograms

The ENTRY statement provides multiple entry points within a subprogram. It is not executable and must precede any CONTAINS statement (if any) within the subprogram. For more information on the ENTRY statement, see ENTRY.

Entry Points in Function Subprograms

If the ENTRY statement is contained in a function subprogram, it defines an additional function. The name of the function is the name specified in the ENTRY statement, and its result variable is the entry name or the name specified by RESULT (if any).

If the entry result variable has the same characteristics as the FUNCTION statement's result variable, their result variables identify the same variable, even if they have different names. Otherwise, the result variables are storage associated and must all be nonpointer scalars of intrinsic type, in one of the following groups:

Group 1	Type default integer, default real, double precision real, default complex, double complex, or default logical
Group 2	Type REAL(16) and COMPLEX(16)
Group 3	Type default character (with identical lengths)

All entry names within a function subprogram are associated with the name of the function subprogram. Therefore, defining any entry name or the name of the function subprogram defines all the associated names with the same data type. All associated names with different data types become undefined.

If RECURSIVE is specified in the FUNCTION statement, all entry points in the FUNCTION are recursive. The interface of the function defined by the ENTRY statement is explicit within the function subprogram.

Examples

The following example shows a function subprogram that computes the hyperbolic functions SINH, COSH, and TANH:

```
REAL FUNCTION TANH(X)
  TSINH(Y) = EXP(Y) - EXP(-Y)
  TCOSH(Y) = EXP(Y) + EXP(-Y)

  TANH = TSINH(X)/TCOSH(X)
  RETURN

  ENTRY SINH(X)
```

```
  SINH = TSINH(X)/2.0
  RETURN

  ENTRY COSH(X)
  COSH = TCOSH(X)/2.0
  RETURN
END
```

See Also

RESULT keyword

Entry Points in Subroutine Subprograms

If the ENTRY statement is contained in a subroutine subprogram, it defines an additional subroutine. The name of the subroutine is the name specified in the ENTRY statement.

If RECURSIVE is specified on the SUBROUTINE statement, all entry points in the subroutine are RECURSIVE. The interface of the subroutine defined by the ENTRY statement is explicit within the subroutine subprogram.

Examples

The following example shows a main program calling a subroutine containing an ENTRY statement:

```
PROGRAM TEST
  ...
  CALL SUBA(A, B, C)       ! A, B, and C are actual arguments
  ...                      !    passed to entry point SUBA
END
SUBROUTINE SUB(X, Y, Z)
  ...
  ENTRY SUBA(Q, R, S)      ! Q, R, and S are dummy arguments
  ...                      ! Execution starts with this statement
END SUBROUTINE
```

The following example shows an ENTRY statement specifying alternate returns:

```
CALL SUBC(M, N, *100, *200, P)
...
SUBROUTINE SUB(K, *, *)
  ...
  ENTRY SUBC(J, K, *, *, X)
  ...
  RETURN 1
  RETURN 2
END
```

Note that the CALL statement for entry point SUBC includes actual alternate return arguments. The RETURN 1 statement transfers control to statement label 100 and the RETURN 2 statement transfers control to statement label 200 in the calling program.

External Procedures

External procedures are user-written functions or subroutines. They are located outside of the main program and can't be part of any other program unit.

External procedures can be invoked by the main program or any procedure of an executable program.

External procedures can include internal subprograms (defining internal procedures). Internal subprograms are placed after a CONTAINS statement.

An external procedure can reference itself (directly or indirectly).

The interface of an external procedure is implicit unless an interface block is supplied for the procedure.

See Also

Functions, Subroutines, and Statement Functions
Procedure Interfaces

Internal Procedures

Internal procedures are functions or subroutines that follow a CONTAINS statement in a program unit. The program unit in which the internal procedure appears is called its *host*.

Internal procedures can appear in the main program, in an external subprogram, or in a module subprogram.

An internal procedure takes the following form:

CONTAINS

internal-subprogram

[*internal-subprogram*] ...

internal-subprogram	Is a function or subroutine subprogram that defines the procedure. An internal subprogram must not contain any other internal subprograms.

Description

Internal procedures are the same as external procedures, except for the following:

- Only the host program unit can use an internal procedure.
- An internal procedure has access to host entities by host association; that is, names declared in the host program unit are useable within the internal procedure.
- An internal procedure must not contain an ENTRY statement.

An internal procedure can reference itself (directly or indirectly); it can be referenced in the execution part of its host and in the execution part of any internal procedure contained in the same host (including itself).

The interface of an internal procedure is always explicit.

Examples

The following example shows an internal procedure:

```
PROGRAM COLOR_GUIDE
...
 CONTAINS
  FUNCTION HUE(BLUE)   ! An internal procedure
  ...
  END FUNCTION HUE
END PROGRAM
```

The following example program contains an internal subroutine `find`, which performs calculations that the main program then prints. The variables `a`, `b`, and `c` declared in the host program are also known to the internal subroutine.

```
program INTERNAL
! shows use of internal subroutine and CONTAINS statement
   real a,b,c
   call find
   print *, c
contains
   subroutine find
    read *, a,b
```

```
    c = sqrt(a**2 + b**2)
   end subroutine find
end
```

Argument Association in Procedures

Procedure arguments provide a way for different program units to access the same data.

When a procedure is referenced in an executable program, the program unit invoking the procedure can use one or more *actual* arguments to pass values to the procedure's *dummy* arguments. The dummy arguments are associated with their corresponding actual arguments when control passes to the subprogram.

In general, when control is returned to the calling program unit, the last value assigned to a dummy argument is assigned to the corresponding actual argument.

An actual argument can be a variable, expression, or procedure name. The type and kind parameters, and rank of the actual argument must match those of its associated dummy argument.

A dummy argument is either a dummy data object, a dummy procedure, or an alternate return specifier (*). Except for alternate return specifiers, dummy arguments can be optional.

If argument keywords are not used, argument association is positional. The first dummy argument becomes associated with the first actual argument, and so on. If argument keywords are used, arguments are associated by the keyword name, so actual arguments can be in a different order than dummy arguments.

A keyword is required for an argument only if a preceding optional argument is omitted or if the argument sequence is changed.

A scalar dummy argument can be associated with only a scalar actual argument.

If a dummy argument is an array, it must be no larger than the array that is the actual argument. You can use adjustable arrays to process arrays of different sizes in a single subprogram.

An actual argument associated with a dummy argument that is allocatable or a pointer must have the same type parameters as the dummy argument.

A dummy argument referenced as a subprogram must be associated with an actual argument that has been declared EXTERNAL or INTRINSIC in the calling routine.

If a scalar dummy argument is of type character, its length must not be greater than the length of its associated actual argument.

If the character dummy argument's length is specified as *(*) (assumed length), it uses the length of the associated actual argument.

Once an actual argument has been associated with a dummy argument, no action can be taken that affects the value or availability of the actual argument, except indirectly through the dummy argument. For example, if the following statement is specified:

```
CALL SUB_A (B(2:6), B(4:10))
```

B(4:6) must not be defined, redefined, or become undefined through either dummy argument, since it is associated with both arguments. However, B(2:3) is definable through the first argument, and B(7:10) is definable through the second argument.

Similarly, if any part of the actual argument is defined through a dummy argument, the actual argument can only be referenced through that dummy argument during execution of the procedure. For example, if the following statements are specified:

```
MODULE MOD_A
  REAL :: A, B, C, D
END MODULE MOD_A

PROGRAM TEST
  USE MOD_A
  CALL SUB_1 (B)
  ...
END PROGRAM TEST

SUBROUTINE SUB_1 (F)
  USE MOD_A
  ...
  WRITE (*,*) F
END SUBROUTINE SUB_1
```

Variable B must not be directly referenced during the execution of SUB_1 because it is being defined through dummy argument F. However, B can be indirectly referenced through F (and directly referenced when SUB_1 completes execution).

The ultimate argument is the effective argument if the effective argument is not a dummy argument or a subobject of a dummy argument. If the effective argument is a dummy argument, the ultimate argument is the ultimate argument of that dummy argument. If the effective argument is a subobject of a dummy argument, the ultimate argument is the corresponding subobject of the ultimate argument of that dummy argument.

Consider the following sequence of subroutine calls:

```
INTEGER :: X(100)
CALL SUBA (X)
...
SUBROUTINE SUBA(A)
INTEGER :: A(:)
CALL SUBB (A(1:5), A(5:1:-1))
...
SUBROUTINE SUBB(B, C)
INTEGER :: B(:), C(:)
```

The ultimate argument of B is X(1:5). The ultimate argument of C is X(5:1:-1), which is not the same object as the ultimate argument of B.

The following sections provide more details on arguments:

- Optional arguments
- The different kinds of arguments:
  - Array arguments
  - Pointer arguments
  - Passed-Object Dummy Arguments
  - Assumed-length character arguments
  - Character constant and Hollerith arguments
  - Alternate return arguments
  - Dummy procedure arguments
  - Coarray Dummy Arguments
- References to generic procedures
- References to non-Fortran procedures (%REF, %VAL, and %LOC)

See Also

CALL for details on argument keywords in subroutine references

Function References for details on argument keywords in function references

Optional Arguments

Dummy arguments can be made optional if they are declared with the OPTIONAL attribute. In this case, an actual argument does not have to be supplied for it in a procedure reference.

If argument keywords are not used, argument association is positional. The first dummy argument becomes associated with the first actual argument, and so on. If argument keywords are used, arguments are associated by the keyword name, so actual arguments can be in a different order than dummy arguments. A keyword is required for an argument only if a preceding optional argument is omitted or if the argument sequence is changed.

Positional arguments (if any) must appear first in an actual argument list, followed by keyword arguments (if any). If an optional argument is the last positional argument, it can simply be omitted if desired.

However, if the optional argument is to be omitted but it is not the last positional argument, keyword arguments must be used for any subsequent arguments in the list.

Optional arguments must have explicit procedure interfaces so that appropriate argument associations can be made.

The PRESENT intrinsic function can be used to determine if an actual argument is associated with an optional dummy argument in a particular reference.

A dummy argument or an entity that is host associated with a dummy argument is not present if any of the following are true for the dummy argument:

- It does not correspond to an actual argument.
- It corresponds to an actual argument that is not present.
- It does not have the ALLOCATABLE or POINTER attribute, and corresponds to one of the following:
  - An actual argument that has the ALLOCATABLE attribute and is not allocated
  - An actual argument that has the POINTER attribute and is disassociated

The following example shows optional arguments:

```
PROGRAM RESULT
TEST_RESULT = LGFUNC(A, B=D)
...
CONTAINS
  FUNCTION LGFUNC(G, H, B)
    OPTIONAL H, B
    ...
  END FUNCTION
END
```

In the function reference, A is a positional argument associated with required dummy argument G. The second actual argument D is associated with optional dummy argument B by its keyword name (B). No actual argument is associated with optional argument H.

The following shows another example:

```
 ! Arguments can be passed out of order, but must be
 !  associated with the correct dummy argument.
 CALL EXT1 (Z=C, X=A, Y=B)
 . . .
 END

 SUBROUTINE EXT1(X,Y,Z)
    REAL X, Y
    REAL, OPTIONAL :: Z
    . . .
 END SUBROUTINE
```

In this case, argument A is associated with dummy argument X by explicit assignment. Once EXT1 executes and returns, A is no longer associated with X, B is no longer associated with Y, and C is no longer associated with Z.

If you pass an omitted dummy argument as the actual argument to a procedure, the corresponding dummy argument is considered to be omitted as well. This applies to both intrinsic and non-intrinsic procedures. For example:

```
CALL SUB1()
CONTAINS
  SUBROUTINE SUB1(B)
  LOGICAL, OPTIONAL :: B
  PRINT *, INDEX('Fortran','r',BACK=B) ! Prints 3
  CALL SUB2(B) ! Same as CALL SUB2()
  END SUBROUTINE SUB1

  SUBROUTINE SUB2(C)
  LOGICAL, OPTIONAL :: C
  PRINT *, PRESENT(C) ! Prints F
  END SUBROUTINE SUB2
END
```

CALL for details on argument keywords in subroutine references
Function References for details on argument keywords in function references

Array Arguments

Arrays are sequences of elements. Each element of an actual array is associated with the element of the dummy array that has the same position in array element order.

If the dummy argument is an explicit-shape or assumed-size array, the size of the dummy argument array must not exceed the size of the actual argument array.

The type and kind parameters of an explicit-shape or assumed-size dummy argument must match the type and kind parameters of the actual argument, but their ranks need not match.

If the dummy argument is an assumed-shape array, the size of the dummy argument array is equal to the size of the actual argument array. The associated actual argument must not be an assumed-size array or a scalar (including a designator for an array element or an array element substring).

If the actual argument is an array section with a vector subscript, the associated dummy argument must not be defined and it must not have the INTENT (OUT), INTENT (INOUT), VOLATILE, or ASYNCHRONOUS attribute.

If an actual argument is an array section or an assumed-shape array, and the corresponding dummy argument has either the VOLATILE or ASYNCHRONOUS attribute, that dummy argument must be an assumed-shape array.

If an actual argument is a pointer array, and the corresponding dummy argument has either the VOLATILE or ASYNCHRONOUS attribute, that dummy argument must be an assumed-shape array or a pointer array.

The declaration of an array used as a dummy argument can specify the lower bound of the array.

If a dummy argument is allocatable, the actual argument must be allocatable and the type parameters and ranks must agree. An example of an allocatable function with allocatable arrays appears in FUNCTION.

Dummy argument arrays declared as assumed-shape, deferred-shape, or pointer arrays require an explicit interface visible to the caller.

Array association
Procedure Interfaces
Argument association for details on general rules for procedure argument association
Array Elements for details on array element order
Explicit-Shape Specifications for details on explicit-shape arrays
Assumed-Shape Specifications for details on assumed-shape arrays
Assumed-Size Specifications for details on assumed-size arrays

Pointer Arguments

An argument is a pointer if it is declared with the POINTER attribute.

When a procedure is invoked, the dummy argument pointer receives the pointer association status of the actual argument. If the actual argument is currently associated, the dummy argument becomes associated with the same target.

The pointer association status of the dummy argument can change during the execution of the procedure, and any such changes are reflected in the actual argument.

If both the dummy and actual arguments are pointers, an explicit interface is required.

A dummy argument that is a pointer can be associated only with an actual argument that is a pointer. However, an actual argument that is a pointer can be associated with a nonpointer dummy argument. In this case, the actual argument is associated with a target and the dummy argument, through argument association, also becomes associated with that target.

If the dummy argument does not have the TARGET or POINTER attribute, any pointers associated with the actual argument do not become associated with the corresponding dummy argument when the procedure is invoked.

If the dummy argument has the TARGET attribute, and is either a scalar or assumed-shape array, and the corresponding actual argument has the TARGET attribute but is not an array section with a vector subscript, the following occurs:

- Any pointer associated with the actual argument becomes associated with the corresponding dummy argument when the procedure is invoked.
- Any pointers associated with the dummy argument remain associated with the actual argument when execution of the procedure completes.

If the dummy argument has the TARGET attribute, and is an explicit-shape or assumed-size array, and the corresponding actual argument has the TARGET attribute but is not an array section with a vector subscript, association of actual and corresponding dummy arguments when the procedure is invoked or when execution is completed is processor dependent.

If the dummy argument has the TARGET attribute and the corresponding actual argument does not have that attribute or is an array section with a vector subscript, any pointer associated with the dummy argument becomes undefined when execution of the procedure completes.

POINTER statement and attribute
Pointer assignments
TARGET statement and attribute
Argument association for details on general rules for procedure argument association

Passed-Object Dummy Arguments

A procedure component or a binding procedure (type-bound procedure) can be declared to have a passed-object dummy argument. This kind of argument is associated with a special actual argument, which is not explicitly written in the actual argument list. The appropriate actual argument is then added to the argument list.

A passed-object dummy argument must be a scalar. It must not be a pointer, must not be allocatable, and all its length type parameters must be assumed. Its declared type must be the type in which the component or binding procedure appears.

The passed-object dummy argument must be a scalar, nonpointer, nonallocatable dummy data object. Its declared type must be the type in which the component or binding appears. All of its length type paramaters must be assumed.

The determination of the passed-object dummy argument depends on the following:

- The PASS and NOPASS attributes specified or in effect
- The interface of the procedure component or binding procedure

The following rules apply to PASS and NOPASS:

- PASS and NOPASS are mutually exclusive. You can only specify one of these attributes for the same procedure component or binding.
- If you specify PASS (*arg-name*), dummy argument *arg-name* is the passed-object dummy argument. The interface of the procedure pointer component or binding procedure must have a dummy argument named *arg-name*.
- If NOPASS is specified, there is no passed-object dummy argument.
- NOPASS must be specified if the procedure component or binding procedure has an implicit interface.
- If you do not specify PASS or NOPASS, or you specify PASS without *arg-name*, the first dummy argument of a procedure pointer component or binding procedure is the passed-object dummy argument. In this case, there must be at least one dummy argument.

See Also

TYPE

Passed-Object Dummy Arguments

Assumed-Length Character Arguments

An assumed-length character argument is a dummy argument that assumes the length attribute of its corresponding actual argument. An asterisk (*) specifies the length of the dummy character argument.

A character array dummy argument can also have an assumed length. The length of each element in the dummy argument is the length of the elements in the actual argument. The assumed length and the array declarator together determine the size of the assumed-length character array.

The following example shows an assumed-length character argument:

```
INTEGER FUNCTION ICMAX(CVAR)
  CHARACTER*(*) CVAR
  ICMAX = 1
  DO I=2,LEN(CVAR)
    IF (CVAR(I:I) .GT. CVAR(ICMAX:ICMAX)) ICMAX=I
  END DO
  RETURN
END
```

The function ICMAX finds the position of the character with the highest ASCII code value. It uses the length of the assumed-length character argument to control the iteration. Intrinsic function LEN determines the length of the argument.

The length of the dummy argument is determined each time control transfers to the function. The length of the actual argument can be the length of a character variable, array element, substring, or expression. Each of the following function references specifies a different length for the dummy argument:

```
CHARACTER VAR*10, CARRAY(3,5)*20
...
I1 = ICMAX(VAR)
I2 = ICMAX(CARRAY(2,2))
I3 = ICMAX(VAR(3:8))
I4 = ICMAX(CARRAY(1,3)(5:15))
I5 = ICMAX(VAR(3:4)//CARRAY(3,5))
```

See Also

LEN intrinsic function

Argument association for details on general rules for procedure argument association

Character Constant and Hollerith Arguments

If an actual argument is a character constant (for example, 'ABCD'), the corresponding dummy argument must be of type character. If an actual argument is a Hollerith constant (for example, 4HABCD), the corresponding dummy argument must have a numeric data type.

The following example shows character and Hollerith constants being used as actual arguments:

```
SUBROUTINE S(CHARSUB, HOLLSUB, A, B)
EXTERNAL CHARSUB, HOLLSUB
...
CALL CHARSUB(A, 'STRING')
CALL HOLLSUB(B, 6HSTRING)
```

The subroutines CHARSUB and HOLLSUB are themselves dummy arguments of the subroutine S. Therefore, the actual argument 'STRING' in the call to CHARSUB must correspond to a character dummy argument, and the actual argument 6HSTRING in the call to HOLLSUB must correspond to a numeric dummy argument.

See Also

Argument association for details on general rules for procedure argument association

Alternate Return Arguments

Alternate return (dummy) arguments can appear in a subroutine argument list. They cause execution to transfer to a labeled statement rather than to the statement immediately following the statement that called the routine. The alternate return is indicated by an asterisk (*). (An alternate return is an obsolescent feature in Standard Fortran.)

There can be any number of alternate returns in a subroutine argument list, and they can be in any position in the list.

An actual argument associated with an alternate return dummy argument is called an alternate return specifier; it is indicated by an asterisk (*) or ampersand (&) followed by the label of an executable branch target statement in the same scoping unit as the CALL statement.

Alternate returns cannot be declared optional.

You can also use the RETURN statement to specify alternate returns.

The following example shows alternate return actual and dummy arguments:

```
CALL MINN(X, Y, *300, *250, Z)
...
SUBROUTINE MINN(A, B, *, *, C)
```

Argument association for details on general rules for procedure argument association
SUBROUTINE statement
CALL statement
RETURN statement
Deleted and Obsolescent Language Features for details on obsolescent features in Standard Fortran

Dummy Procedure Arguments

If an actual argument is a procedure, its corresponding dummy argument is a dummy procedure. Dummy procedures can appear in function or subroutine subprograms.

The actual argument must be the specific name of an external, module, intrinsic, or another dummy procedure. If the specific name is also a generic name, only the specific name is associated with the dummy argument. Not all specific intrinsic procedures can appear as actual arguments. (For more information, see table Specific Functions Not Allowed as Actual Arguments in Intrinsic Procedures.)

The actual argument and corresponding dummy procedure must both be subroutines or both be functions.

If the interface of the dummy procedure is explicit, the type and kind parameters, and rank of the associated actual procedure must be the same as that of the dummy procedure.

If the interface of the dummy procedure is implicit and the procedure is referenced as a subroutine, the actual argument must be a subroutine or a dummy procedure.

If the interface of the dummy procedure is implicit and the procedure is referenced as a function or is explicitly typed, the actual argument must be a function or a dummy procedure.

Dummy procedures can be declared optional, but they must not be declared with an intent.

The following is an example of a procedure used as an argument:

```
REAL FUNCTION LGFUNC(BAR)
  INTERFACE
    REAL FUNCTION BAR(Y)
      REAL, INTENT(IN) :: Y
    END
  END INTERFACE
  ...
  LGFUNC = BAR(2.0)
  ...
END FUNCTION LGFUNC
```

Argument association for details on general rules for procedure argument association

Coarray Dummy Arguments

If a dummy argument is a coarray, the corresponding actual argument must be a coarray and must have the VOLATILE attribute if and only if the dummy argument has the VOLATILE attribute.

If a dummy argument is an array coarray that has the CONTIGUOUS attribute or is not of assumed shape, the corresponding actual argument must be simply contiguous.

Examples

When a procedure is invoked on a particular image, each dummy coarray is associated with its ultimate argument on the image. During the execution of the procedure, this image can access the coarray corresponding to the ultimate argument on any other image. For example, consider the following:

```
INTERFACE
   SUBROUTINE MY_SUB(Y)
      REAL :: Y[*]
   END SUBROUTINE MY_SUB
END INTERFACE
...
REAL :: B(700)[:]
...
CALL MY_SUB(B(10))
```

When subroutine MY_SUB is invoked, the executing image has access through the syntax Y[P] to B(10) on image P.

Each invocation of a procedure with a nonallocatable coarray dummy argument establishes a dummy coarray for the image with its own bounds and cobounds. During the execution of the procedure, this image may use its own bounds and cobounds to access the coarray corresponding to the ultimate argument on any other image. For example, consider the following:

```
INTERFACE
   SUBROUTINE MY_SUB(Y,I)
      INTEGER :: I
      REAL :: Y(I,I)[I,*]
   END SUBROUTINE MY_SUB
END INTERFACE
...
REAL :: B(1000)[:]
...
CALL MY_SUB(B,10)
```

When subroutine MY_SUB is invoked, the executing image has access through the syntax Y(1,2)[3,4] to B(11) on the image with image index 33.

References to Generic Procedures

Generic procedures are procedures with different specific names that can be accessed under one generic (common) name. In FORTRAN 77, generic procedures were limited to intrinsic procedures. In the current Fortran standard, you can use generic interface blocks to specify generic properties for intrinsic and user-defined procedures.

If you refer to a procedure by using its generic name, the selection of the specific routine is based on the number of arguments and the type and kind parameters, and rank of each argument.

All procedures given the same generic name must be subroutines, or all must be functions. Any two must differ enough so that any invocation of the procedure is unambiguous.

The following sections describe references to generic intrinsic functions and show an example of using intrinsic function names.

See Also

Unambiguous Generic Procedure References

Intrinsic procedures

Resolving Procedure References

Defining Generic Names for Procedures for details on user-defined generic procedures

References to Generic Intrinsic Functions

The generic intrinsic function name COS lists six specific intrinsic functions that calculate cosines: COS, DCOS, QCOS, CCOS, CDCOS, and CQCOS. These functions return different values: REAL(4), REAL(8), REAL(16), COMPLEX(4), COMPLEX(8), and COMPLEX(16) respectively.

If you invoke the cosine function by using the generic name COS, the compiler selects the appropriate routine based on the arguments that you specify. For example, if the argument is REAL(4), COS is selected; if it is REAL(8), DCOS is selected; and if it is COMPLEX(4), CCOS is selected.

You can also explicitly refer to a particular routine. For example, you can invoke the double-precision cosine function by specifying DCOS.

Procedure selection occurs independently for each generic reference, so you can use a generic reference repeatedly in the same program unit to access different intrinsic procedures.

You cannot use generic function names to select intrinsic procedures if you use them as follows:

- The name of a statement function
- A dummy argument name, a common block name, or a variable or array name

When an intrinsic function is passed as an actual argument to a procedure, its specific name must be used, and when called, its arguments must be scalar. Not all specific intrinsic functions can appear as actual arguments. (For more information, see table Specific Functions Not Allowed as Actual Arguments in Intrinsic Procedures.)

A reference to a generic intrinsic procedure name in a program unit does not prevent use of the name for other purposes elsewhere in the program.

Normally, an intrinsic procedure name refers to the Fortran library procedure with that name. However, the name can refer to a user-defined procedure when the name appears in an EXTERNAL statement.

NOTE
If you call an intrinsic procedure by using the wrong number of arguments or an incorrect argument type, the compiler assumes you are referring to an external procedure. For example, intrinsic procedure SIN requires one argument; if you specify two arguments, such as SIN(10,4), the compiler assumes SIN is external and not intrinsic.

The data type of an intrinsic procedure does not change if you use an IMPLICIT statement to change the implied data type rules.

Intrinsic and user-defined procedures cannot have the same name if they appear in the same program unit.

Examples

The following example shows the local and global properties of an intrinsic function name. It uses the name SIN in different procedures as follows:

- The name of a statement function
- The generic name of an intrinsic function
- The specific name of an intrinsic function
- The name of a user-defined function

Using and Redefining an Intrinsic Function Name

```
!    Compare ways of computing sine
     PROGRAM SINES
       DOUBLE PRECISION X, PI
       PARAMETER (PI=3.14159265358979323 8D0)
       COMMON V(3)
```

```
!    Define SIN as a statement function  1
       SIN(X) = COS(PI/2-X)
       print *
       print *, "                    Way of computing SIN(X)"
       print *
       print *, "      X       Statement   Intrinsic   Intrinsic     User's "
       print *, "              function      DSIN       SIN as arg     SIN  "
       print *
       DO X = -PI, PI, PI/2
                  CALL COMPUT(X)
!    References the statement function SIN  2
                  WRITE (6,100) X, SIN(X), V
        END DO
100     FORMAT (5F12.7)
      END

      SUBROUTINE COMPUT(Y)
        DOUBLE PRECISION Y

!    Use intrinsic function SIN - double-precision DSIN will be passed
!       as an actual argument  3
        INTRINSIC SIN
        COMMON V(3)

!    Makes the generic name SIN reference the double-precision sine DSIN  4
        V(1) = SIN(Y)

!    Use intrinsic function SIN as an actual argument - will pass DSIN 5
         CALL SUB(REAL(Y),SIN)
      END

      SUBROUTINE SUB(A,S)

!    Declare SIN as name of a user function  6
         EXTERNAL SIN
!    Declare SIN as type DOUBLE PRECISION  7
         DOUBLE PRECISION SIN
         COMMON V(3)

!    Evaluate intrinsic function SIN passed as the dummy argument 8
         V(2) = S(A)

!    Evaluate user-defined SIN function  9
         V(3) = SIN(A)
      END

!    Define the user SIN function  10
      DOUBLE PRECISION FUNCTION SIN(X)
         INTEGER FACTOR
         SIN = X - X**3/FACTOR(3) + X**5/FACTOR(5)     &
             - X**7/FACTOR(7)
      END
```

```
!    Compute the factorial of N
       INTEGER FUNCTION FACTOR(N)
          FACTOR = 1
          DO I=N,1,-1
             FACTOR = FACTOR * I
          END DO
       END
```

1 The statement function named SIN is defined in terms of the generic function name COS. Because the argument of COS is double precision, the double-precision cosine function is evaluated. The statement function SIN is itself single precision.

2 The statement function SIN is called.

3 The name SIN is declared intrinsic so that the single-precision intrinsic sine function can be passed as an actual argument at 5.

4 The generic function name SIN is used to refer to the double-precision sine function.

5 The single-precision intrinsic sine function is used as an actual argument.

6 The name SIN is declared a user-defined function name.

7 The type of SIN is declared double precision.

8 The single-precision sine function passed at 5 is evaluated.

9 The user-defined SIN function is evaluated.

10 The user-defined SIN function is defined as a simple Taylor series using a user-defined function FACTOR to compute the factorial function.

References to Elemental Intrinsic Procedures

An *elemental intrinsic procedure* has scalar dummy arguments that can be called with scalar or array actual arguments. If actual arguments are array-valued, they must have the same shape. There are many elemental intrinsic functions, but only one elemental intrinsic subroutine (MVBITS).

If the actual arguments are scalar, the result is scalar. If the actual arguments are array-valued, the scalar-valued procedure is applied element-by-element to the actual argument, resulting in an array that has the same shape as the actual argument.

The values of the elements of the resulting array are the same as if the scalar-valued procedure had been applied separately to the corresponding elements of each argument.

For example, if A and B are arrays of shape (5,6), MAX(A, 0.0, B) is an array expression of shape (5,6) whose elements have the value MAX(A (i, j), 0.0, B (i, j)), where i = 1, 2,..., 5, and j = 1, 2,..., 6.

A reference to an elemental intrinsic procedure is an elemental reference if one or more actual arguments are arrays and all array arguments have the same shape.

Examples

Consider the following:

```
REAL, DIMENSION (2) :: a, b
a(1) = 4; a(2) = 9
b = SQRT(a)                ! sets b(1) = SQRT(a(1)), and b(2) = SQRT(a(2))
```

Intrinsic procedures for details on elemental procedures

References to Non-Fortran Procedures

When a procedure is called, Fortran (by default) passes the address of the actual argument, and its length if it is of type character. To call non-Fortran procedures, you may need to pass the actual arguments in a form different from that used by Fortran.

The built-in functions %REF and %VAL let you change the form of an actual argument. You must specify these functions in the actual argument list of a CALL statement or function reference. You cannot use them in any other context.

%LOC computes the internal address of a storage item.

Procedure Interfaces

Every procedure has an interface, which consists of the name and characteristics of a procedure, the name and characteristics of each dummy argument, and the generic identifier (if any) by which the procedure can be referenced. The characteristics of a procedure are fixed, but the remainder of the interface can change in different scoping units.

If these properties are all known within the scope of the calling program, the procedure interface is explicit; otherwise it is implicit (deduced from its reference and declaration). The following table shows which procedures have implicit or explicit interfaces:

Kind of Procedure	Interface
External procedure	Implicit [1]
Module procedure	Explicit
Internal procedure	Explicit
Intrinsic procedure	Explicit
Dummy procedure	Implicit [1]
Statement function	Implicit

[1] This kind of procedure is explicit in a scoping unit other than its own if an interface body for the procedure is supplied or is accessible.

The interface of a recursive subroutine or function is explicit within the subprogram that defines it.

An explicit interface can come from any of the following:

- An interface block
- The procedure's definition in a module
- An internal procedure

A procedure must not access through use association its own interface.

An abstract interface lets you give a name to a set of characteristics and argument keyword names that create an explicit interface to a procedure. It does not declare any actual procedure to have those characteristics.

Depending on the characteristics of the procedure and its dummy arguments, an explicit interface may be required to be visible to its caller. For more information see Procedures that Require Explicit Interfaces.

You can use a procedure declaration statement to declare procedure pointers, dummy procedures, and external procedures. It specifies the EXTERNAL attribute for all procedure entities in the procedure declaration list.

You can use the IMPORT statement to make host entities accessible in the interface body of an interface block.

You can specify the ALLOCATABLE, OPTIONAL, or POINTER attributes for a dummy argument in a procedure interface that has the BIND attribute.

Examples

An example of an interface block follows:

```
INTERFACE
  SUBROUTINE Ext1 (x, y, z)
  REAL, DIMENSION (100,100) :: x, y, z
  END SUBROUTINE Ext1

  SUBROUTINE Ext2 (x, z)
  REAL x
  COMPLEX (KIND = 4) z (2000)
  END SUBROUTINE Ext2

  FUNCTION Ext3 (p, q)
  LOGICAL Ext3
  INTEGER p (1000)
  LOGICAL q (1000)
  END FUNCTION Ext3
END INTERFACE
```

IMPORT

Procedures that Require Explicit Interfaces

When a procedure is referenced, it must have an explicit interface in the following cases:

- If a reference to the procedure appears in one of the following:
  - An actual argument that is specified with a keyword
  - In a context that requires it to be PURE
- If the procedure has a dummy argument that is one of the following:
  - An object that has the ALLOCATABLE, ASYNCHRONOUS, OPTIONAL, POINTER, TARGET, VALUE, or VOLATILE attribute
  - An assumed-shape array
  - A polymorphic object (an object declared with a CLASS statement)
  - A coarray (an object declared with a CODIMENSION attribute or statement)
  - An object of a parameterized derived type
  - An object of assumed-rank or assumed-type
- If the procedure has any of the following:

  - A result that is an array, or a pointer, or is allocatable (functions only)
  - A result whose length is neither assumed nor a constant (character functions only)
- If a reference to the procedure appears as follows:
  - With an argument keyword
  - As a reference by its generic name
  - As a defined assignment (subroutines only)
  - In an expression as a defined operator (functions only)
  - In a context that requires it to be pure
- If the procedure is elemental
- If the procedure has the BIND attribute

Statement functions do not require an explicit interface.

Explicit and Abstract Interfaces

An explicit interface defines characteristics for external or dummy procedures. It can also be used to define a generic name for procedures, a new operator for functions, and a new form of assignment for subroutines. For more information, see INTERFACE.

An abstract interface defines a subprogram whose name can be used in a PROCEDURE declaration statement to declare subprograms with identical arguments and characteristics. For more information, see ABSTRACT INTERFACE and PROCEDURE.

Defining Generic Names for Procedures

An interface block or a GENERIC statement can be used to specify a generic name to reference all of the procedures within the interface block.

The initial line for such an interface block takes the following form:

INTERFACE *generic-name*

generic-name	Is the generic name. It can be the same as any of the procedure names in the interface block, or the same as any accessible generic name (including a generic intrinsic name). A generic name can be the same as a derived-type name. In this case, all of the procedures in the interface block must be functions.

A generic interface can be used to extend or redefine a generic intrinsic procedure.

The procedures that are given the generic name must be the same kind of subprogram: all must be functions, or all must be subroutines.

Any procedure reference involving a generic procedure name must be resolvable to one specific procedure; it must be unambiguous. For more information, see Unambiguous Generic Procedure References.

The following is an example of a procedure interface block defining a generic name:

```
INTERFACE GROUP_SUBS
  SUBROUTINE INTEGER_SUB (A, B)
    INTEGER, INTENT(INOUT) :: A, B
  END SUBROUTINE INTEGER_SUB

  SUBROUTINE REAL_SUB (A, B)
    REAL, INTENT(INOUT) :: A, B
  END SUBROUTINE REAL_SUB

  SUBROUTINE COMPLEX_SUB (A, B)
    COMPLEX, INTENT(INOUT) :: A, B
  END SUBROUTINE COMPLEX_SUB
END INTERFACE
```

The three subroutines can be referenced by their individual specific names or by the group name GROUP_SUBS.

The following example shows a reference to INTEGER_SUB:

```
INTEGER V1, V2
CALL GROUP_SUBS (V1, V2)
```

Consider the following:

```
 INTERFACE LINE_EQUATION

   SUBROUTINE REAL_LINE_EQ(X1,Y1,X2,Y2,M,B)
     REAL,INTENT(IN) :: X1,Y1,X2,Y2
     REAL,INTENT(OUT) :: M,B
   END SUBROUTINE REAL_LINE_EQ

   SUBROUTINE INT_LINE_EQ(X1,Y1,X2,Y2,M,B)
     INTEGER,INTENT(IN) :: X1,Y1,X2,Y2
     INTEGER,INTENT(OUT) :: M,B
   END SUBROUTINE INT_LINE_EQ

 END INTERFACE
```

In this example, LINE_EQUATION is the generic name which can be used for either REAL_LINE_EQ or INT_LINE_EQ. Fortran selects the appropriate subroutine according to the nature of the arguments passed to LINE_EQUATION. Even when a generic name exists, you can always invoke a procedure by its specific name. In the previous example, you can call REAL_LINE_EQ by its specific name (REAL_LINE_EQ), or its generic name LINE_EQUATION.

See Also

INTERFACE statement for details on interface blocks

GENERIC statement for an alternate to interface blocks for declaring generic procedures

Defining Generic Operators

An interface block can be used to define a generic operator. The only procedures allowed in the interface block are functions that can be referenced as defined operations.

The initial line for such an interface block takes the following form:

INTERFACE OPERATOR (*op*)

op	Is one of the following:

- A defined unary operator (one argument)
- A defined binary operator (two arguments)
- An extended intrinsic operator (number of arguments must be consistent with the intrinsic uses of that operator)

The functions within the interface block must have one or two nonoptional arguments with intent IN, and the function result must not be of type character with assumed length. A defined operation is treated as a reference to the function.

The following shows the form (and an example) of a defined unary and defined binary operation:

Operation	Form	Example
Defined Unary	.defined-operator. operand[1]	.MINUS. C
Defined Binary	operand[2] .defined-operator. operand[3]	B .MINUS. C

[1] The operand corresponds to the function's dummy argument.

[2] The left operand corresponds to the first dummy argument of the function.

[3] The right operand corresponds to the second argument.

For intrinsic operator symbols, the generic properties include the intrinsic operations they represent. Both forms of each relational operator have the same interpretation, so extending one form (such as >=) defines both forms (>= and .GE.).

The following is an example of a procedure interface block defining a new operator:

```
INTERFACE OPERATOR(.BAR.)
  FUNCTION BAR(A_1)
    INTEGER, INTENT(IN) :: A_1
    INTEGER :: BAR
  END FUNCTION BAR
END INTERFACE
```

The following example shows a way to reference function BAR by using the new operator:

```
INTEGER B
I = 4 + (.BAR. B)
```

The following is an example of a procedure interface block with a defined operator extending an existing operator:

```
INTERFACE OPERATOR(+)
  FUNCTION LGFUNC (A, B)
    LOGICAL, INTENT(IN) :: A(:), B(SIZE(A))
    LOGICAL :: LGFUNC(SIZE(A))
  END FUNCTION LGFUNC
END INTERFACE
```

The following example shows two equivalent ways to reference function LGFUNC:

```
LOGICAL, DIMENSION(1:10) :: C, D, E
N = 10
E = LGFUNC(C(1:N), D(1:N))
E = C(1:N) + D(1:N)
```

INTERFACE for details on interface blocks

Expressions for details on intrinsic operators

Defined Operations for details on defined operators and operations

Defining Generic Assignment

An interface block can be used to define generic assignment. The only procedures allowed in the interface block are subroutines that can be referenced as defined assignments.

The initial line for such an interface block takes the following form:

INTERFACE ASSIGNMENT (=)

The subroutines within the interface block must have two nonoptional arguments, the first with intent OUT or INOUT, and the second with intent IN and/or attribute VALUE.

A defined assignment is treated as a reference to a subroutine. The left side of the assignment corresponds to the first dummy argument of the subroutine; the right side of the assignment corresponds to the second argument.

The ASSIGNMENT keyword extends or redefines an assignment operation if both sides of the equal sign are of the same derived type.

Defined elemental assignment is indicated by specifying ELEMENTAL in the SUBROUTINE statement.

Any procedure reference involving generic assignment must be resolvable to one specific procedure; it must be unambiguous. For more information, see Unambiguous Generic Procedure References.

The following is an example of a procedure interface block defining assignment:

```
INTERFACE ASSIGNMENT (=)
  SUBROUTINE BIT_TO_NUMERIC (NUM, BIT)
    INTEGER, INTENT(OUT) :: NUM
    LOGICAL, INTENT(IN)  :: BIT(:)
  END SUBROUTINE BIT_TO_NUMERIC

  SUBROUTINE CHAR_TO_STRING (STR, CHAR)
    USE STRING_MODULE                   ! Contains definition of type STRING
    TYPE(STRING), INTENT(OUT) :: STR    ! A variable-length string
    CHARACTER(*), INTENT(IN)  :: CHAR
  END SUBROUTINE  CHAR_TO_STRING
END  INTERFACE
```

The following example shows two equivalent ways to reference subroutine BIT_TO_NUMERIC:

```
CALL BIT_TO_NUMERIC(X, (NUM(I:J)))
X = NUM(I:J)
```

The following example shows two equivalent ways to reference subroutine CHAR_TO_STRING:

```
CALL CHAR_TO_STRING(CH, '432C')
CH = '432C'
```

Defined Assignments
INTENT attribute
INTERFACE statement for details on interface blocks

Interoperability of Procedures and Procedure Interfaces

A Fortran procedure is interoperable if it has the BIND attribute.

A Fortran procedure interface is interoperable with a C function prototype if the following is true:

- The interface has the BIND attribute
- One of the following is true:
  - The interface describes a function whose result variable is a scalar that is interoperable with the result of the prototype.

  - The interface describes a subroutine and the prototype has a result type of void.
- The number of dummy arguments of the interface is equal to the number of formal parameters of the prototype.
- Any dummy argument with the VALUE attribute is interoperable with the corresponding formal parameter of the prototype.
- Any dummy argument without the VALUE attribute corresponds to a formal parameter of the prototype that is of a pointer type, and one of the following is true:
  - The dummy argument is interoperable with an entity of the referenced type of the formal parameter.
  - The dummy argument is a nonallocatable nonpointer variable of type CHARACTER with assumed character length and the formal parameter is a pointer to the C descriptior descriptor CFI_cdesc_t.
  - The dummy argument is allocatable, assumed-shape, assumed-rank, or a pointer without the CONTIGUOUS attribute, and the formal parameter is a pointer to the C descriptior descriptor CFI_cdesc_t.
  - The dummy argument is assumed-type and not allocatable, assumed-shape, assumed-rank, or a pointer, and the formal parameter is a pointer to void.
- Each allocatable or pointer dummy argument of type CHARACTER has deferred character length.
- The prototype does not have variable arguments as denoted by an ellipsis (...).

In an invocation of an interoperable procedure whose Fortran interface has an assumed-shape or assumed-rank dummy argument with the CONTIGUOUS attribute, the associated effective argument can be an array that is not contiguous or it can be the address of a C descriptor for such an array.

If the procedure is invoked from Fortran or the procedure is a Fortran procedure, the Fortran processor will handle the difference in contiguity.

If the procedure is invoked from C or the procedure is a C procedure, the C code within the procedure must be able to handle the situation of receiving a discontiguous argument.

An actual argument that is absent in a reference to an interoperable procedure is indicated by a corresponding formal parameter with the value of a null pointer. An optional dummy argument that is absent in a reference to an interoperable procedure from a C function is indicated by a corresponding argument with the value of a null pointer.

The following rules also apply:

- C functions must not invoke a function pointer whose value is the result of a reference to C_FUNLOC with a noninteroperable argument.
- When passing an argument to a C procedure where the corresponding C formal parameter is a C descriptor, Fortran must pass a C descriptor and, on return, ensure that any updates to the C descriptor are reflected in Fortran.
- If the interface specifies that the dummy argument is CONTIGUOUS, the passed argument (and the C descriptor's description of that argument, if relevant) must be contiguous.
- A Fortran procedure with BIND(C) that has a dummy argument that is assumed-length CHARACTER or is allocatable, assumed-shape, assumed-rank, or a pointer without CONTIGUOUS must accept that argument as a C descriptor and make sure that on return, the C descriptor reflects any changes made to the argument during execution of the Fortran procedure.
- A Fortran procedure with one of the following arguments must accept that argument as a C descriptor and make sure that on return, the C descriptor reflects any changes made to the argument during execution of the Fortran procedure:
  - A dummy argument that is assumed-length CHARACTER
  - A dummy argument that is allocatable, assumed-shape, assumed-rank, or a pointer without CONTIGUOUS

Procedure Pointers

A procedure pointer has the POINTER attribute and points to a procedure instead of a data object. It can be associated with an external procedure, a module procedure, an intrinsic procedure, or a dummy procedure that is not a procedure pointer. It can have an implicit or explicit interface, but the interface cannot be generic or elemental.

A procedure pointer can be one of the following:

- A named pointer (described below)

- A derived-type component (See Procedure Pointers as Derived-Type Components.)

Procedure Pointers as Named Pointers

You can declare a procedure pointer in a procedure declaration statement by including the POINTER attribute. For example:

```
PROCEDURE(QUARK), POINTER :: Q => NULL()
```

The above declares Q to be a procedure pointer with interface QUARK; it also initializes Q to be a disassociated pointer.

A named procedure pointer can also be declared by specifying the POINTER attribute in addition to the normal procedure declaration.

The following example uses a type declaration statement to declare a procedure pointer:

```
POINTER :: MyP
INTERFACE
  SUBROUTINE MyP(c,d)
    REAL, INTENT(INOUT) :: c
    REAL, INTENT(IN) :: d
  END SUBROUTINE MyP
END INTERFACE
REAL, EXTERNAL, POINTER :: MyR
```

The above specifies that MyP is a pointer to a subroutine with an explicit interface. It also specifies that MyR is a pointer to a scalar REAL function with an implicit interface.

Note that in a type declaration statement, you must specify the EXTERNAL attribute as well as the POINTER attribute when declaring the procedure pointer.

INTERFACE
ABSTRACT INTERFACE
PROCEDURE

Intrinsic Procedures

Intrinsic procedures are functions and subroutines that are included in the Fortran library. The following are classes of intrinsic procedures:

- Elemental procedures

  These procedures have scalar dummy arguments that can be called with scalar or array actual arguments. There are many elemental intrinsic functions and one elemental intrinsic subroutine (MVBITS). All elemental intrinsic procedures are pure.

  If the arguments are all scalar, the result is scalar. If an actual argument is array-valued, the intrinsic procedure is applied to each element of the actual argument, resulting in an array that has the same shape as the actual argument.

  If there is more than one array-valued argument, they must all have the same shape.

  Many algorithms involving arrays can now be written conveniently as a series of computations with whole arrays. For example, consider the following:

```
a = b + c
...               ! a, b, c, and s are all arrays of similar shape
s = sum(a)
```

  The above statements can replace entire DO loops.

Consider the following:

```
real, dimension (5,5) :: x,y
. . .      ! Assign values to x
y = sin(x) ! Pass the entire array as an argument
```

In this example, since the SIN(X) function is an elemental procedure, it operates element-by-element on the array x when you pass it the name of the whole array.

- Inquiry functions

  These functions have results that depend on the properties of their principal argument, not the value of the argument (the argument value can be undefined).
- Transformational functions

  These functions have one or more array-valued dummy or actual arguments, an array result, or both. The intrinsic function is not applied elementally to an array-valued actual argument; instead it changes (transforms) the argument array into another array.
- Nonelemental procedures

  These procedures must be called with only scalar arguments; they return scalar results. All subroutines (except MVBITS) are nonelemental.
- Atomic subroutines

  These subroutines perform an action on a variable (its *atom* argument) atomically. When an atomic subroutine is executed, it is as if the subroutine were executed instantaneously without overlapping other atomic actions that might occur asynchronously. For information on the semantics of atomic subroutines, see Overview of Atomic Subroutines.
- Collective subroutines

  These subroutines perform a cooperative calculation on a team of images and require no synchronization. For information on the semantics of collective subroutines, see Overview of Collective Subroutines.

The intrinsic subroutine MVBITS, and the subroutine MOVE_ALLOC with a noncoarray argument FROM, are pure. All other intrinsic subroutines are impure.

Intrinsic procedures are invoked the same way as other procedures, and follow the same rules of argument association.

The intrinsic procedures have generic (or common) names, and many of the intrinsic functions have specific names. (Some intrinsic functions are both generic and specific.)

In general, generic functions accept arguments of more than one data type; the data type of the result is the same as that of the arguments in the function reference. For elemental functions with more than one argument, all arguments must be of the same type (except for the function MERGE).

When an intrinsic function is passed as an actual argument to a procedure, its specific name must be used, and when called, its arguments must be scalar. Some specific intrinsic functions are not allowed as actual arguments in all circumstances. The following table lists specific functions that cannot be passed as actual arguments or as targets in procedure pointer assignment statements.

Starting with Fortran 2018, specific names of intrinsic functions that also have generic names are obsolescent.

Specific Intrinsic Functions Not Allowed as Actual Arguments

AIMAX0	FLOATJ	JFIX	MAX0
AIMIN0	FLOATK	JIDINT	MAX1
AJMAX0	FP_CLASS	JIFIX	MIN0
AJMIN0	HFIX	JINT	MIN1
AKMAX0	IADDR	JIQINT	NARGS
AKMIN0	IARGC	JMAX0	QCMPLX
AMAX0	ICHAR	JMAX1	QEXT

AMAX1	IDINT	JMIN0	QEXTD
AMIN0	IFIX	JMIN1	QMAX1
AMIN1	IIDINT	JNUM	QMIN1
CHAR	IIFIX	JZEXT	QNUM
CMPLX	IINT	KIDINT	QREAL
DBLE	IIQINT	KIFIX	RAN
DBLEQ	IJINT	KINT	RANF
DCMPLX	IMAX0	KIQINT	REAL
DFLOTI	IMAX1	KMAX0	RNUM
DFLOTJ	IMIN0	KMAX1	SECNDS
DFLOTK	IMIN1	KMIN0	SHIFTL
DMAX1	INT	KMIN1	SHIFTR
DMIN1	INT1	KNUM	SNGL
DNUM	INT2	KZEXT	SNGLQ
DREAL	INT4	LGE	ZEXT
DSHIFTL	INT8	LGT	
DSHIFTR	INUM	LLE	
FLOAT	IQINT	LLT	
FLOATI	IZEXT	LOC	

Note that none of the intrinsic subroutines can be passed as actual arguments or as targets in procedure pointer assignment statements.

The A to Z Reference contains the descriptions of all intrinsics listed in alphabetical order. Each reference entry indicates whether the procedure is inquiry, elemental, transformational, or nonelemental, and whether it is a function or a subroutine.

Argument Keywords in Intrinsic Procedures

For all intrinsic procedures, the arguments shown are the names you must use as keywords when using the keyword form for actual arguments. For example, a reference to function CMPLX(X, Y, KIND) can be written as follows:

Using positional arguments:	CMPLX(F, G, L)
Using argument keywords: [1]	CMPLX(KIND=L, Y=G, X=F)

[1] Note that argument keywords can be written in any order.

Some argument keywords are optional (denoted by square brackets). The following describes some of the most commonly used optional arguments:

BACK	Specifies that a string scan is to be in reverse order (right to left).
DIM	Specifies a selected dimension of an array argument.
KIND	Specifies the kind type parameter of the function result.
MASK	Specifies that a mask can be applied to the elements of the argument array to exclude the elements that are not to be involved in an operation.

Examples

The syntax for the DATE_AND_TIME intrinsic subroutine shows four optional positional arguments: DATE, TIME, ZONE, and VALUES. The following shows some valid ways to specify these arguments:

```
! Keyword example
CALL DATE_AND_TIME (ZONE=Z)

! Positional example
CALL DATE_AND_TIME (DATE, TIME, ZONE)
```

Argument Association

Overview of Atomic Subroutines

Atomic subroutines are impure intrinsic procedures that perform an action on their *atom* argument atomically. If a reference to an atomic subroutine has an *old* argument, the value to be assigned to that argument is also determined atomically with the action performed on the *atom* argument. The evaluation or definition of any other argument is not performed atomically.

The *stat* argument, if present, has a value of zero if no error condition occurs during the subroutine reference.

If *stat* is present and an error condition occurs, any INTENT(INOUT) or INTENT(OUT) argument becomes undefined. If the *atom* argument is on a failed image, *stat*, if present, becomes defined with the value STAT_FAILED_IMAGE from the intrinsic module ISO_FORTRAN_ENV and an error condition occurs. If any other error condition occurs, *stat* becomes defined with a processor-dependent positive integer value other than that of STAT_FAILED_IMAGE.

If an error condition occurs and *stat* is not present, error termination is initiated.

For a list of all atomic intrinsic subroutines, including links to the subroutine's full description, see Atomic Intrinsic Subroutines.

Overview of Collective Subroutines

Collective subroutines are impure intrinsic subroutines that perform a calculation on a team of images, assigning the result to one of the images or all of the images on the current team. Synchronization is not required. When the collective subroutine is invoked, it is invoked by the same statement on all active images of the current team. Corresponding references to the subroutine participate in the same collective operation.

The sequence of invocations of collective subroutines must be the same across all active images of the current team. A collective subroutine cannot be invoked anywhere an image control statement is not permitted. For example, a pure procedure or a critical construct cannot contain a reference to a collective subroutine.

If argument *a* in an invocation of a collective subroutine is a coarray, it must ultimately be the same coarray on each active image of the current team.

If argument *stat* is present in the reference to a collective subroutine on one image, it must be present in corresponding references on all images of the current team.

Successful execution of a collective subroutine causes the value of *stat*, if present, to become defined with the value 0.

If an error condition occurs during the reference to the collective subroutine and *stat* is present, *stat* is assigned a positive value and argument *a* becomes undefined. If *stat* is present and the current team contains a stopped image, an error condition occurs and *stat* becomes defined with the value STAT_STOPPED_IMAGE defined in the intrinsic module ISO_FORTRAN_ENV. Otherwise, if the current team contains a failed image, an error condition occurs and *stat* becomes defined with the value STAT_FAILED_IMAGE from ISO_FORTRAN_ENV. If any other error condition occurs, *stat* becomes defined with a positive integer value other than STAT_STOPPED_IMAGE or STAT_FAILED_IMAGE.

If *stat* is not present in a reference to a collective subroutine and an error condition occurs during the reference, error termination is initiated.

If argument *errmsg* is present when an error condition occurs, it becomes defined with an explanatory message, padded with blanks or truncated as necessary. If no error condition occurs, the value and definition status of *errmsg* is not changed.

Internal synchronization occurs during a reference to a collective subroutine, but a statement containing a reference to a collective subroutine is not an image control statement.

For a list of all collective intrinsic subroutines, including links to the subroutine's full description, see Collective Intrinsic Subroutines.

Overview of Bit Functions

Integer data types are represented internally in binary two's complement notation. Bit positions in the binary representation are numbered from right (least significant bit) to left (most significant bit); the rightmost bit position is numbered 0.

The intrinsic functions IAND, IOR, IEOR, and NOT operate on all of the bits of their argument (or arguments). Bit 0 of the result comes from applying the specified logical operation to bit 0 of the argument. Bit 1 of the result comes from applying the specified logical operation to bit 1 of the argument, and so on for all of the bits of the result.

The functions ISHFT and ISHFTC shift binary patterns.

The functions IBSET, IBCLR, BTEST, and IBITS and the subroutine MVBITS operate on bit fields.

A *bit field* is a contiguous group of bits within a binary pattern. Bit fields are specified by a starting bit position and a length. A bit field must be entirely contained in its source operand.

For example, the integer 47 is represented by the following:

Binary pattern:	0...0101111
Bit position:	n...6543210 Where *n* is the number of bit positions in the numeric storage unit.

You can refer to the bit field contained in bits 3 through 6 by specifying a starting position of 3 and a length of 4.

Negative integers are represented in two's complement notation. For example, the integer -47 is represented by the following:

Binary pattern:	1...1010001
Bit position:	n...6543210 Where n is the number of bit positions in the numeric storage unit.

The value of bit position n is as follows:

```
  1 for a negative number
  0 for a non-negative number
```

All the high-order bits in the pattern from the last significant bit of the value up to bit n are the same as bit n.

IBITS and MVBITS operate on general bit fields. Both the starting position of a bit field and its length are arguments to these intrinsics. IBSET, IBCLR, and BTEST operate on 1-bit fields. They do not require a length argument.

For IBSET, IBCLR, and BTEST, the bit position range is as follows:

- 0 to 63 for INTEGER(8) and LOGICAL(8)
- 0 to 31 for INTEGER(4) and LOGICAL(4)
- 0 to 15 for INTEGER(2) and LOGICAL(2)
- 0 to 7 for BYTE, INTEGER(1), and LOGICAL(1)

For IBITS, the bit position can be any number. The length range is 0 to 63 on Intel® 64 architecture; 0 to 31 on IA-32 architecture.

The following example shows IBSET, IBCLR, and BTEST:

```
I = 4
J = IBSET (I,5)
PRINT *, 'J = ',J
K = IBCLR (J,2)
PRINT *, 'K = ',K
PRINT *, 'Bit 2 of K is ',BTEST(K,2)
END
```

The results are: J = 36, K = 32, and Bit 2 of K is F.

For optimum selection of performance and memory requirements, Intel® Fortran provides the following integer data types:

Data Type	Storage Required (in bytes)
INTEGER(1)	1
INTEGER(2)	2
INTEGER(4)	4
INTEGER(8)	8

The bit manipulation functions each have a generic form that operates on all of these integer types and a specific form for each type.

When you specify the intrinsic functions that refer to bit positions or that shift binary patterns within a storage unit, be careful that you do not create a value that is outside the range of integers representable by the data type. If you shift by an amount greater than or equal to the size of the object you're shifting, the result is 0.

Consider the following:

```
INTEGER(2) I,J
I = 1
J = 17
I = ISHFT(I,J)
```

The variables I and J have INTEGER(2) type. Therefore, the generic function ISHFT maps to the specific function IISHFT, which returns an INTEGER(2) result. INTEGER(2) results must be in the range -32768 to 32767, but the value 1, shifted left 17 positions, yields the binary pattern 1 followed by 17 zeros, which represents the integer 131072. In this case, the result in I is 0.

The previous example would be valid if I was INTEGER(4), because ISHFT would then map to the specific function JISHFT, which returns an INTEGER(4) value.

If ISHFT is called with a constant first argument, the result will either be the default integer size or the smallest integer size that can contain the first argument, whichever is larger.

Categories and Lists of Intrinsic Procedures

This section describes the categories of generic intrinsic functions (including a summarizing table) and lists the intrinsic subroutines.

Intrinsic procedures are fully described (in alphabetical order) in the A to Z Reference.

Categories of Intrinsic Functions

Generic intrinsic functions can be divided into categories, as shown in the following table:

Categories of Intrinsic Functions

Category	Subcategory	Description
Numeric	Computation	Elemental functions that perform type conversions or simple numeric operations: ABS, AIMAG, AINT, AMAX0, AMIN0, ANINT, CEILING, CMPLX, CONJG, DBLE, DCMPLX, DFLOAT, DIM, DNUM, DPROD, DREAL, FLOAT, FLOOR, IFIX, IMAG, INT, INUM, JNUM, KNUM MAX, MAX1, MIN, MIN1, MOD, MODULO, NINT, QCMPLX, QEXT, QFLOAT, QNUM, QREAL, REAL, RNUM, SIGN, SNGL, ZEXT
		Nonelemental function that provides a pseudorandom number: RAN
		Elemental function that generates a random number: RANF
	Manipulation[1]	Elemental functions that return values related to the components of the model values associated with the actual value of the argument: EXPONENT, FRACTION, NEAREST, RRSPACING, SCALE, SET_EXPONENT, SPACING
	Inquiry[1]	Functions that return scalar values from the models associated with the type and kind parameters of their arguments[2]: DIGITS, EPSILON, HUGE, ILEN,

Category	Subcategory	Description
		MAXEXPONENT, MINEXPONENT, PRECISION, RADIX, RANGE, SIZEOF, TINY
	Transformational	Functions that perform vector and matrix multiplication: DOT_PRODUCT, MATMUL
	System	Functions that return information about a process or processor: MCLOCK, SECNDS
Kind type		Functions that return kind type parameters: KIND, SELECTED_CHAR_KIND, SELECTED_INT_KIND, SELECTED_REAL_KIND
Mathematical		Elemental functions that perform mathematical operations: ACOS, ACOSD, ACOSH, ASIN, ASIND, ASINH, ATAN, ATAN2, ATAN2D,ATAND, ATANH, BESSEL_J0, BESSEL_J1, BESSEL_JN, BESSEL_Y0, BESSEL_Y1, BESSEL_YN, COS, COSD, COSH,COTAN, COTAND, EXP, EXP10, GAMMA, HYPOT, LOG, LOG10, LOG_GAMMA, SIN, SIND, SINH, SQRT, TAN, TAND, TANH
Bit	Manipulation	Elemental functions that perform bit operations, such as single-bit processing, logical and shift operations, and allowing bit subfields to be referenced: AND, BGE, BGT, BLE, BLT, BTEST, DSHIFTL, DSHIFTR, IAND, IBCHNG, IBCLR, IBITS, IBSET, IEOR, IOR, ISHA, ISHC, ISHFT, ISHFTC, ISHL, IXOR,LSHIFT, MASKL, MASKR, MERGE_BITS, NOT, OR, RSHIFT, SHIFTA, SHIFTL, SHIFTR, XOR
	Inquiry	Function that lets you determine bit size and storage size: BIT_SIZE, STORAGE_SIZE
	Representation	Elemental functions that return information on bit representation of integers: LEADZ, POPCNT, POPPAR, TRAILZ
Character	Comparison	Elemental functions that make a lexical comparison of the character-string arguments and return a default logical result: LGE, LGT, LLE, LLT

Category	Subcategory	Description
	Conversion	Elemental functions that take character arguments and return integer, ASCII, or character values[4]: ACHAR, CHAR, IACHAR, ICHAR
	String handling	Functions that perform operations on character strings, return lengths of arguments, and search for certain arguments: Elemental: ADJUSTL, ADJUSTR, INDEX, LEN_TRIM, SCAN, VERIFY; Nonelemental: REPEAT, TRIM
	Inquiry	Functions that return the length of an argument or information about command-line arguments: COMMAND_ARGUMENT_COUNT, IARG, IARGC, LEN, NARGS, NUMARG
Array	Construction	Functions that construct new arrays from the elements of existing arrays: Elemental: MERGE; Nonelemental: PACK, SPREAD, UNPACK
	Inquiry	Functions that let you determine if an array argument is allocated, and return the size or shape of an array, and the lower and upper bounds of subscripts along each dimension: ALLOCATED, IS_CONTIGUOUS, LBOUND, RANK, SHAPE, SIZE, UBOUND
	Location	Transformational functions that find the geometric locations of the maximum and minimum values of an array, and find the location of a specified value in an array: MAXLOC, MINLOC, FINDLOC
	Manipulation	Transformational functions that shift an array, transpose an array, or change the shape of an array: CSHIFT, EOSHIFT, RESHAPE, TRANSPOSE
	Reduction	Transformational functions that perform operations on arrays. The functions "reduce" elements of a whole array to produce a scalar result, or they can be applied to a specific dimension of an array to produce a result array with a rank reduced by one: ALL,

Category	Subcategory	Description
		ANY, COUNT, IALL, IANY, IPARITY, MAXVAL, MINVAL, NORM2, PARITY, PRODUCT, SUM
Coarray	Inquiry	Functions that return execution status of an image, convert cosubscripts, or return sizes of codimensions, or lower or upper cobounds: Elemental: IMAGE_STATUS Nonelemental: COSHAPE, IMAGE_INDEX, LCOBOUND, UCOBOUND
	Transformational	Functions that return the number of images or cosubscripts, or return image indices of failed or stopped images: NUM_IMAGES, THIS_IMAGE, FAILED_IMAGES, STOPPED_IMAGES
Polymorphic	Inquiry	Functions that let you determine the dynamic type of an object: EXTENDS_TYPE_OF, SAME_TYPE_AS
Miscellaneous		Functions that do the following: • Check for pointer association (ASSOCIATED) • Return an address (BADDRESS or IADDR) • Return the size of a level of the memory cache (CACHESIZE) • Check for end-of-file (EOF) • Return error functions (ERF, ERFC,and ERFC_SCALED) • Return the class of a floating-point argument (FP_CLASS) • Return the INTEGER KIND that will hold an address (INT_PTR_KIND) • Test for Not-a-Number values (ISNAN) • Return the internal address of a storage item (LOC) • Return a logical value of an argument (LOGICAL) • Allocate memory (MALLOC) • Return a new line character (NEW_LINE) • Return a disassociated pointer (NULL) • Check for argument presence (PRESENT) • Convert a bit pattern (TRANSFER)

Category	Subcategory	Description
		• Check for end-of-file condition (IS_IOSTAT_END) • Check for end-of-record condition (IS_IOSTAT_EOR)

[1] All of the numeric manipulation, and many of the numeric inquiry functions are defined by the model sets for integers and reals.

[2] The value of the argument does not have to be defined.

[3] For more information on bit functions, see Bit functions.

[4] The Intel® Fortran processor character set is ASCII, so ACHAR = CHAR and IACHAR = ICHAR.

The following table summarizes the generic intrinsic functions and indicates whether they are elemental, inquiry, or transformational functions. Optional arguments are shown within square brackets.

Some intrinsic functions are specific with no generic association. These functions are listed below.

Summary of Generic Intrinsic Functions

Generic Function	Class	Value Returned
ABS (A)	E	The absolute value of an argument
ACHAR (I [,KIND])	E	The character in the specified position of the ASCII character set
ACOS (X)	E	The arccosine (in radians) of the argument
ACOSD (X)	E	The arccosine (in degrees) of the argument
ACOSH (X)	E	The hyperbolic arccosine of the argument
ADJUSTL (STRING)	E	The specified string with leading blanks removed and placed at the end of the string
ADJUSTR (STRING)	E	The specified string with trailing blanks removed and placed at the beginning of the string
AIMAG (Z)	E	The imaginary part of a complex argument
AINT (A [,KIND])	E	A real value truncated to a whole number
ALL (MASK [,DIM])	T	.TRUE. if all elements of the masked array are true
ALLOCATED ([ARRAY=]array) or ALLOCATED ([SCALAR=]scalar)	I	The allocation status of the argument array or scalar
AMAX0 (A1, A2 [, A3,...])	E	The maximum value in a list of integers (returned as a real value)

Generic Function	Class	Value Returned
AMIN0 (A1, A2 [, A3,...])	E	The minimum value in a list of integers (returned as a real value)
AND (I, J)	E	See IAND
ANINT (A [, KIND])	E	A real value rounded to a whole number
ANY (MASK [, DIM])	T	.TRUE. if any elements of the masked array are true
ASIN (X)	E	The arcsine (in radians) of the argument
ASIND (X)	E	The arcsine (in degrees) of the argument
ASINH (X)	E	The hyperbolic arcsine of the argument
ASSOCIATED (POINTER [,TARGET])	I	.TRUE. if the pointer argument is associated or the pointer is associated with the specified target
ATAN (X)	E	The arctangent (in radians) of the argument
ATAN2 (Y, X)	E	The arctangent (in radians) of the arguments
ATAN2D (Y, X)	E	The arctangent (in degrees) of the arguments
ATAND (X)	E	The arctangent (in degrees) of the argument
ATANH (X)	E	The hyperbolic arctangent of the argument
BADDRESS (X)	I	The address of the argument
BESSEL_J0 (X)	E	A Bessel function of the first kind, order 0
BESSEL_J1 (X)	E	A Bessel function of the first kind, order 1
BESSEL_JN (N, X)	E	A Bessel function of the first kind, order N
BESSEL_JN (N1, N2, X)	T	A Bessel function of the first kind
BESSEL_Y0 (X)	E	A Bessel function of the second kind, order 0
BESSEL_Y1 (X)	E	A Bessel function of the second kind, order 1
BESSEL_YN (N, X)	E	A Bessel function of the second kind, order N

Generic Function	Class	Value Returned
BESSEL_YN (N1, N2, X)	T	A Bessel function of the second kind
BGE (I, J)	E	Bitwise greater than or equal to
BGT (I, J)	E	Bitwise greater than
BIT_SIZE (I)	I	The number of bits (*s*) in the bit model
BLE (I, J)	E	Bitwise less than or equal to
BLT (I, J)	E	Bitwise less than
BTEST (I, POS)	E	.TRUE. if the specified position of argument I is one
CEILING (A [,KIND])	E	The smallest integer greater than or equal to the argument value
CHAR (I [,KIND])	E	The character in the specified position of the processor character set
COMMAND_ARGUMENT_COUNT ()	I	The number of command arguments
CONJG (Z)	E	The conjugate of a complex number
COS (X)	E	The cosine of the argument, which is in radians
COSD (X)	E	The cosine of the argument, which is in degrees
COSH (X)	E	The hyperbolic cosine of the argument
COSHAPE (COARRAY [,KIND])	I	The sizes of codimensions of a coarray.
COTAN (X)	E	The cotangent of the argument, which is in radians
COTAND (X)	E	The cotangent of the argument, which is in degrees
COUNT (MASK [, DIM, KIND])	T	The number of .TRUE. elements in the argument array
CSHIFT (ARRAY, SHIFT [,DIM])	T	An array that has the elements of the argument array circularly shifted
DBLE (A)	E	The corresponding double precision value of the argument
DFLOAT (A)	E	The corresponding double precision value of the integer argument

Generic Function	Class	Value Returned
DIGITS (X)	I	The number of significant digits in the model for the argument
DIM (X, Y)	E	The positive difference between the two arguments
DOT_PRODUCT (VECTOR_A, VECTOR_B)	T	The dot product of two rank-one arrays (also called a vector multiply function)
DREAL (A)	E	The corresponding double-precision value of the double complex argument
DSHIFTL (ILEFT, IRIGHT, ISHIFT)	E	The upper (leftmost) 64 bits of a left-shifted 128-bit integer
DSHIFTR (ILEFT, IRIGHT, ISHIFT)	E	The lower (rightmost) 64 bits of a right-shifted 128-bit integer
EOF (A)	I	.TRUE. or .FALSE. depending on whether a file is beyond the end-of-file record
EOSHIFT (ARRAY, SHIFT [,BOUNDARY] [,DIM])	T	An array that has the elements of the argument array end-off shifted
EPSILON (X)	I	The number that is almost negligible when compared to one
ERF (X)	E	The error function of an argument
ERFC (X)	E	The complementary error function of an argument
ERFC_SCALED (X)	E	The scaled complementary error function of an argument
EXP (X)	E	The exponential e^x for the argument x
EXPONENT (X)	E	The value of the exponent part of a real argument
EXTENDS_TYPE_OF (A, MOLD)	I	Whether one dynamic type is an extension of another dynamic type
FAILED_IMAGES ([KIND])	T	Image indices of images known to have failed on the specified or current team
FINDLOC (ARRAY, VALUE, DIM [, MASK, KIND, BACK]) or FINDLOC (ARRAY, VALUE [, MASK, KIND, BACK])	T	Location of a specified value in an array.
FLOAT (X)	E	The corresponding real value of the integer argument

Generic Function	Class	Value Returned
FLOOR (A [,KIND])	E	The largest integer less than or equal to the argument value
FP_CLASS (X)	E	The class of the IEEE floating-point argument
FRACTION (X)	E	The fractional part of a real argument
GAMMA (X)	E	A gamma function
HUGE (X)	I	The largest number in the model for the argument
HYPOT (X, Y)	E	A Euclidean distance function
IACHAR (C [,KIND])	E	The position of the specified character in the ASCII character set
IADDR (X)	E	See BADDRESS
IAND (I, J)	E	The logical AND of the two arguments
IALL (ARRAY, DIM [, MASK]) or IALL (ARRAY [, MASK])	T	The result of a bitwise AND operation
IANY (ARRAY, DIM [, MASK]) or IANY (ARRAY [, MASK])	T	The result of a bitwise OR operation
IBCLR (I, POS)	E	The specified position of argument I cleared (set to zero)
IBCHNG (I, POS)	E	The reversed value of a specified bit
IBITS (I, POS, LEN)	E	The specified substring of bits of argument I
IBSET (I, POS)	E	The specified bit in argument I set to one
ICHAR (C [, KIND])	E	The position of the specified character in the processor character set
IEOR (I, J)	E	The logical exclusive OR of the corresponding bit arguments
IFIX (X)	E	The corresponding integer value of the real argument rounded as if it were an implied conversion in an assignment
ILEN (I)	I	The length (in bits) in the two's complement representation of an integer
IMAG (Z)	E	See AIMAG
IMAGE_INDEX (COARRAY, SUB)	T	The index of the corresponding image

Generic Function	Class	Value Returned
IMAGE_STATUS (IMAGE)	E	Execution status of the specified image number on the specified or current team
INDEX (STRING, SUBSTRING [, BACK, KIND])	E	The position of the specified substring in a character expression
INT (A [, KIND])	E	The corresponding integer value (truncated) of the argument
IOR (I, J)	E	The logical inclusive OR of the corresponding bit arguments
IPARITY (ARRAY, DIM [, MASK]) or IPARITY (ARRAY [, MASK])	T	The result of a bitwise exclusive OR operation
IS_CONTIGUOUS (ARRAY)	I	The contiguity of an array
IS_IOSTAT_END (I)	E	.TRUE. for an end-of-file condition
IS_IOSTAT_EOR (I)	E	.TRUE. for an end-of-record condition
ISHA (I, SHIFT)	E	Argument I shifted left or right by a specified number of bits
ISHC (I, SHIFT)	E	Argument I rotated left or right by a specified number of bits
ISHFT (I, SHIFT)	E	The logical end-off shift of the bits in argument I
ISHFTC (I, SHIFT [,SIZE])	E	The logical circular shift of the bits in argument I
ISHL (I, SHIFT)	E	Argument I logically shifted left or right by a specified number of bits
ISNAN (X)	E	Tests for Not-a-Number (NaN) values
IXOR (I, J)	E	See IEOR
KIND (X)	I	The kind type parameter of the argument
LBOUND (ARRAY [, DIM, KIND])	I	The lower bounds of an array (or one of its dimensions)
LEADZ (I)	E	The number of leading zero bits in an integer
LEN (STRING [,KIND])	I	The length (number of characters) of the argument character string
LEN_TRIM (STRING [,KIND])	E	The length of the specified string without trailing blanks

Generic Function	Class	Value Returned
LGE (STRING_A, STRING_B)	E	A logical value determined by a > or = comparison of the arguments
LGT (STRING_A, STRING_ B)	E	A logical value determined by a > comparison of the arguments
LLE (STRING_A, STRING_B)	E	A logical value determined by a < or = comparison of the arguments
LLT (STRING_A, STRING_B)	E	A logical value determined by a < comparison of the arguments
LOC (A)	I	The internal address of the argument.
LOG (X)	E	The natural logarithm of the argument
LOG10 (X)	E	The common logarithm (base 10) of the argument
LOG_GAMMA (X)	E	The logarithm of the absolute value of the gamma function
LOGICAL (L [,KIND])	E	The logical value of the argument converted to a logical of type KIND
LSHIFT (I, POSITIVE_SHIFT)	E	See ISHFT
LSHFT (I, POSITIVE_SHIFT)	E	Same as LSHIFT; see ISHFT
MALLOC (I)	E	The starting address for the block of memory allocated
MASKL (I [,KIND])	E	A left-justified mask
MASKR (I [,KIND])	E	A right-justified mask
MATMUL (MATRIX_A, MATRIX_B)	T	The result of matrix multiplication (also called a matrix multiply function)
MAX (A1, A2 [, A3,...])	E	The maximum value in the set of arguments
MAX1 (A1, A2 [, A3,...])	E	The maximum value in the set of real arguments (returned as an integer)
MAXEXPONENT (X)	I	The maximum exponent in the model for the argument
MAXLOC (ARRAY, DIM [, MASK, KIND, BACK]) or MAXLOC (ARRAY [, MASK, KIND, BACK])	T	The rank-one array that has the location of the maximum element in the argument array
MAXVAL (ARRAY, DIM [, MASK]) or MAXVAL (ARRAY [, MASK])	T	The maximum value of the elements in the argument array

Generic Function	Class	Value Returned
MERGE (TSOURCE, FSOURCE, MASK)	E	An array that is the combination of two conformable arrays (under a mask)
MERGE_BITS (I, J, MASK)	E	The merge of bits under a mask
MIN (A1, A2 [, A3,...])	E	The minimum value in the set of arguments
MIN1 (A1, A2 [, A3,...])	E	The minimum value in the set of real arguments (returned as an integer)
MINEXPONENT (X)	I	The minimum exponent in the model for the argument
MINLOC (ARRAY, DIM [, MASK, KIND, BACK]) or MINLOC (ARRAY [, MASK, KIND, BACK])	T	The rank-one array that has the location of the minimum element in the argument array
MINVAL (ARRAY, DIM [, MASK]) or MAXVAL (ARRAY [, MASK])	T	The minimum value of the elements in the argument array
MOD (A, P)	E	The remainder of the arguments (has the sign of the first argument)
MODULO (A, P)	E	The modulo of the arguments (has the sign of the second argument)
NEAREST (X, S)	E	The nearest different machine-representable number in a given direction
NEW_LINE (A)	I	A new line character
NINT (A [,KIND])	E	A real value rounded to the nearest integer
NORM2 (X [,DIM])	T	The L2 norm of an array
NOT (I)	E	The logical complement of the argument
NULL ([MOLD])	T	A disassociated pointer
NUM_IMAGES ()	T	The number of images
OR (I, J)	E	See IOR
PACK (ARRAY, MASK [,VECTOR])	T	A packed array of rank one (under a mask)
PARITY (MASK [, DIM])	T	The result of an exclusive OR operation
POPCNT (I)	E	The number of 1 bits in the integer argument
POPPAR (I)	E	The parity of the integer argument

Generic Function	Class	Value Returned
PRECISION (X)	I	The decimal precision (real or complex) of the argument
PRESENT (A)	I	.TRUE. if an actual argument has been provided for an optional dummy argument
PRODUCT (ARRAY, DIM [,MASK]) or PRODUCT (ARRAY [, MASK])	T	The product of the elements of the argument array
QEXT (A)	E	The corresponding REAL(16) precision value of the argument
QFLOAT (A)	E	The corresponding REAL(16) precision value of the integer argument
RADIX (X)	I	The base of the model for the argument
RANGE (X)	I	The decimal exponent range of the model for the argument
RANF ()	E	A random number between 0.0 and RAND_MAX
RANK (A)	I	The rank of a data object
REAL (A [, KIND])	E	The corresponding real value of the argument
REPEAT (STRING, NCOPIES)	T	The concatenation of zero or more copies of the specified string
RESHAPE (SOURCE, SHAPE [, PAD,ORDER])	T	An array that has a different shape than the argument array, but the same elements
RRSPACING (X)	E	The reciprocal of the relative spacing near the argument
RSHIFT (I, NEGATIVE_SHIFT)	E	See ISHFT
RSHFT (I, N EGATIVE_SHIFT)	E	Same as RSHIFT; see ISHFT
SAME_TYPE_AS (A, B)	I	Whether two dynamic types are the same.
SCALE (X, I)	E	The value of the exponent part (of the model for the argument) changed by a specified value
SCAN (STRING, SET [, BACK, KIND])	E	The position of the specified character (or set of characters) within a string
SELECTED_CHAR_KIND (NAME)	T	The value of the kind type parameter of the character set named by the argument

Generic Function	Class	Value Returned
SELECTED_INT_KIND (R)	T	The integer kind parameter of the argument
SELECTED_REAL_KIND ([P, R, RADIX])	T	The real kind parameter of the argument; one of the optional arguments must be specified
SET_EXPONENT (X, I)	E	The value of the exponent part (of the model for the argument) set to a specified value
SHAPE (SOURCE [,KIND])	I	The shape (rank and extents) of an array or scalar
SHIFTA (I, SHIFT)	E	A right shift with fill
SHIFTL (I, SHIFT)	E	Argument IVALUE shifted left by a specified number of bits
SHIFTR (I, SHIFT)	E	Argument IVALUE shifted right by a specified number of bits
SIGN (A, B)	E	A value with the sign transferred from its second argument
SIN (X)	E	The sine of the argument, which is in radians
SIND (X)	E	The sine of the argument, which is in degreess
SINH (X)	E	The hyperbolic sine of the argument
SIZE (ARRAY [, DIM, KIND])	I	The size (total number of elements) of the argument array (or one of its dimensions)
SIZEOF (X)	I	The bytes of storage used by the argument
SNGL (X)	E	The corresponding real value of the argument
SPACING (X)	E	The value of the absolute spacing of model numbers near the argument
SPREAD (SOURCE, DIM, NCOPIES)	T	A replicated array that has an added dimension
SQRT (X)	E	The square root of the argument
STOPPED_IMAGES ([KIND])	T	Image indices of stopped images on the specified or current team
STORAGE_SIZE (A [,KIND])	I	The storage size in bits
SUM (ARRAY, DIM] [, MASK]) or SUM (ARRAY [, MASK])	T	The sum of the elements of the argument array
TAN (X)	E	The tangent of the argument, which is in radians

Generic Function	Class	Value Returned
TAND (X)	E	The tangent of the argument, which is in degrees
TANH (X)	E	The hyperbolic tangent of the argument
THIS_IMAGE () or THIS_IMAGE (COARRAY [, DIM])	T	The index of the invoking image or the cosubscripts for the image
TINY (X)	I	The smallest positive number in the model for the argument
TRAILZ (I)	E	The number of trailing zero bits in an integer
TRANSFER (SOURCE, MOLD [,SIZE])	T	The bit pattern of SOURCE converted to the type and kind parameters of MOLD
TRANSPOSE (MATRIX)	T	The matrix transpose for the rank-two argument array
TRIM (STRING)	T	The argument with trailing blanks removed
UBOUND (ARRAY [, DIM, KIND])	I	The upper bounds of an array (or one of its dimensions)
UNPACK (VECTOR, MASK, FIELD)	T	An array (under a mask) unpacked from a rank-one array
VERIFY (STRING, SET [, BACK, KIND])	E	The position of the first character in a string that does not appear in the given set of characters
XOR (I, J)	E	See IEOR
ZEXT (X [,KIND])	E	A zero-extended value of the argument

I-Inquiry

T-Transformational

The following table lists specific functions that have no generic function associated with them and indicates whether they are elemental, nonelemental, or inquiry functions. Optional arguments are shown within square brackets.

Specific Functions with No Generic Association

Generic Function	Class	Value Returned
CACHESIZE (N)	I	The size of a level of the memory cache
CMPLX (X [,KIND]) or CMPLX (X [,Y, KIND])	E	The corresponding complex value of the argument
DCMPLX (X, Y)	E	The corresponding double complex value of the argument

Generic Function	Class	Value Returned
DNUM (I)	E	The corresponding REAL(8) value of a character string
DPROD (X, Y)	E	The double-precision product of two real arguments
DREAL (A)	E	The corresponding double-precision value of the double-complex argument
IARG ( )	I	See IARGC
IARGC ( )	I	The index of the last command-line argument
INT_PTR_KIND ( )	I	The INTEGER kind that will hold an address
INUM (I)	E	The corresponding INTEGER(2) value of a character string
JNUM (I)	E	The corresponding INTEGER(4) value of a character string
KNUM (I)	E	The corresponding INTEGER(8) value of a character string
MCLOCK ( )	I	The sum of the current process's user time and the user and system time of all its child processes
NARGS ( )	I	The total number of command-line arguments, including the command
NUMARG ( )	I	See IARGC
QCMPLX (X, Y)	E	The corresponding COMPLEX(16) value of the argument
QNUM (I)	E	The corresponding REAL(16) value of a character string
QREAL (A)	E	The corresponding REAL(16) value of the real part of a COMPLEX(16) argument
RAN (I)	N	The next number from a sequence of pseudorandom numbers (uniformly distributed in the range 0 to 1)
RNUM (I)	E	The corresponding REAL(4) value of a character string
SECNDS (X)	E	The system time of day (or elapsed time) as a floating-point value in seconds

N-Nonelemental		

Intrinsic Subroutines

The following table lists the intrinsic subroutines. Optional arguments are shown within square brackets. All these subroutines are nonelemental except for MVBITS. All of these subroutines, with the exception of MVBITS, and MOVE_ALLOC with a noncoarray FROM argument, are impure. None of the intrinsic subroutines can be passed as actual arguments.

Intrinsic Subroutines

Subroutine	Value Returned or Result
ATOMIC_ADD (atom, value [, stat])	Performs atomic addition.
ATOMIC_AND (atom, value [, stat])	Performs atomic bitwise AND.
ATOMIC_CAS (atom, old, compare, new [,stat])	Performs atomic compare and swap.
ATOMIC_DEFINE (atom, value [, stat])	Defines a variable atomically.
ATOMIC_FETCH_ADD (atom, value, old [, stat])	Performs atomic fetch and addition.
ATOMIC_FETCH_AND (atom, value, old [, stat])	Performs atomic fetch and bitwise AND.
ATOMIC_FETCH_OR (atom, value, old [, stat])	Performs atomic fetch and bitwise OR.
ATOMIC_FETCH_XOR (atom, value, old [, stat])	Performs atomic fetch and bitwise exclusive OR.
ATOMIC_OR (atom, value [, stat])	Performs atomic bitwise OR.
ATOMIC_REF (value, atom [, stat])	References a variable atomically.
ATOMIC_XOR (atom, value [, stat])	Performs atomic bitwise exclusive OR.
CO_BROADCAST (a, source_image [, stat, errmsg])	Broadcasts a value to other images.
CO_MAX (a, result_image [, stat, errmsg])	Computes maximum value across images.
CO_MIN (a, result_image [, stat, errmsg])	Computes minimum value across images.
CO_REDUCE (a, operation [, result_image, stat, errmsg])	Performs a generalized reduction across images.
CO_SUM (a, result_image [, stat, errmsg])	Performs a sum reduction across images.
CPU_TIME (time)	Returns the processor time in seconds.
DATE (buf)	Returns the ASCII representation of the current date (in dd-mmm-yy form).
DATE_AND_TIME ([date] [,time] [,zone] [,values])	Returns the date and time information from the real-time clock.
ERRSNS ([io_err] [,sys_err] [,stat] [,unit] [,cond])	Returns information about the most recently detected error condition.
EVENT_QUERY (event, count [, stat])	Queries an event count.
EXECUTE_COMMAND_LINE (command [, wait, exitstat, cmdstat, cmdmsg])	Executes the command line.

Subroutine	Value Returned or Result
EXIT ([status])	Image exit status is optionally returned; the program is terminated, all files closed, and control is returned to the operating system.
FREE (a)	Frees memory that is currently allocated.
GETARG (n, buffer [,status])	Returns the specified command line argument (where the command itself is argument number zero).
GET_COMMAND ([command, length, status])	Returns the entire command that was used to invoke the program.
GET_COMMAND_ARGUMENT (n [, value, length, status])	Returns a command line argument of the command that invoked the program.
GET_ENVIRONMENT_VARIABLE (name [, value, length, status, trim_name])	Returns the value of an environment variable.
IDATE (i, j, k)	Returns three integer values representing the current month, day, and year.
MM_PREFETCH (address [,hint] [,fault] [,exclusive])	Returns data from the specified address on one memory cache line.
MOVE_ALLOC (from, to [, stat, errmsg])	Causes an allocation to be moved from one allocatable object to another.
MVBITS (from, frompos, len, to, topos)[1]	Causes a sequence of bits (bit field) to be copied from one location to another.
RANDOM_NUMBER (harvest)	Returns a pseudorandom number taken from a sequence of pseudorandom numbers uniformly distributed within the range 0.0 to 1.0.
RANDOM_SEED ([size] [,put] [,get])	Causes the initialization or retrieval of the pseudorandom number generator seed value.
RANDU (i1, i2, x)	Returns a pseudorandom number as a single-precision value (within the range 0.0 to 1.0).
SYSTEM_CLOCK ([count] [,count_rate] [,count_max])	Returns data from the processors real-time clock.
TIME (buf)	Returns the ASCII representation of the current time (in hh:mm:ss form).

[1] An elemental subroutine

Data Transfer I/O Statements

Input/Output (I/O) statements can be used for data transfer, file connection, file inquiry, and file positioning.

This section discusses data transfer and contains information on the following topics:

- An overview of records and files
- Components of data transfer statements
- Data transfer input statements:
  - READ

Data can be input from external sequential or direct-access records, or from internal records.
- ACCEPT

  This statement is the same as a formatted, sequential READ statement, except that an ACCEPT statement must never be connected to user-specified I/O units.
- Data transfer output statements:
  - WRITE

    Data can be output to external sequential or direct-access records, or to internal records.
  - PRINT and TYPE

    The PRINT statement is the same as a formatted, sequential WRITE statement, except that the PRINT statement must never transfer data to user-specified I/O units.

    TYPE is a synonym for PRINT. All forms and rules for the PRINT statement also apply to the TYPE statement.
  - REWRITE

    It rewrites the current record and it can be formatted or unformatted.

File connection, file inquiry, and file positioning I/O statements are discussed in File Operation I O Statements.

Records and Files

A record is a sequence of values or a sequence of characters. There are three kinds of Fortran records, as follows:

- Formatted

  A record containing formatted data that requires translation from internal to external form. Formatted I/O statements have explicit format specifiers (which can specify list-directed formatting) or namelist specifiers (for namelist formatting). Only formatted I/O statements can read formatted data.
- Unformatted

  A record containing unformatted data that is not translated from internal form. An unformatted record can also contain no data. The internal representation of unformatted data is processor- dependent. Only unformatted I/O statements can read unformatted data.
- Endfile

  The last record of a file. An endfile record can be explicitly written to a sequential file by an ENDFILE statement.

A file is a sequence of records. There are two types of Fortran files, as follows:

- External

  A file that exists in a medium (such as computer disks or terminals) external to the executable program.

  Records in an external file must be either all formatted or all unformatted. There are two ways to access records in external files: sequential and direct access.

  In sequential access, records are processed in the order in which they appear in the file. In direct access, records are selected by record number, so they can be processed in any order.
- Internal

  Memory (internal storage) that behaves like a file. This type of file provides a way to transfer and convert data in memory from one format to another. The contents of these files are stored as scalar character variables.

Unit Specifier (UNIT=)

Components of Data Transfer Statements

Data transfer statements take one of the following forms:

io-keyword (*io-control-list*) [*io-list*]

io-keywordformat [, *io-list*]

io-keyword

Is one of the following: ACCEPT, PRINT (or TYPE), READ, REWRITE, or WRITE.

io-control-list

Is one or more of the following input/output (I/O) control specifiers:

[UNIT=]io-unit	ASYNCHRONOUS	IOMSG	SIZE
[FMT=]format	END	IOSTAT	
[NML=]group	EOR	POS	
ADVANCE	ERR	REC	

io-list

Is an I/O list, which can contain variables (except for assumed-size arrays) or implied-DO lists. Output statements can contain constants or expressions.

format

Is the nonkeyword form of a control-list format specifier (no FMT=).

If a format specifier ([FMT=]format) or namelist specifier ([NML=]group) is present, the data transfer statement is called a formatted I/O statement; otherwise, it is an unformatted I/O statement.

If a record specifier (REC=) is present, the data transfer statement is a direct-access I/O statement; otherwise, it is a sequential-access I/O statement.

If an error, end-of-record, or end-of-file condition occurs during data transfer, file positioning and execution are affected, and certain control-list specifiers (if present) become defined. (For more information, see Branch Specifiers.)

Following sections describe the I/O control list and I/O lists.

I/O Control List

The I/O control list specifies one or more of the following:

- The I/O unit to act upon ([UNIT=]io-unit)

  This specifier must be present; the rest are optional.
- The format (explicit or list-directed) to use for data editing; if explicit, the keyword form must appear ([FMT=]
- The namelist group name to act upon ([NML=]group)
- The number of a record to access (REC=)
- The name of a variable that contains the completion status of an I/O operation (IOSTAT=)
- The label of the statement that receives control if an error (ERR=), end-of-file (END=), or end-of-record (EOR=) condition occurs
- Whether you want to use advancing or nonadvancing I/O (ADVANCE=)
- The number of characters read from a record (SIZE=)
- Whether you want to use asynchronous or synchronous I/O (ASYNCHRONOUS=)
- The identifier for a pending data transfer operation (ID=)
- The identifier for the file position in file storage units in a stream file (POS=)
- The name of a variable that contains an error message (IOMSG=)

No control specifier can appear more than once, and the list must not contain both a format specifier and namelist group name specifier.

Control specifiers can take any of the following forms:

- Keyword form

  When the keyword form (for example, UNIT=io-unit) is used for all control-list specifiers in an I/O statement, the specifiers can appear in any order.

- Nonkeyword form

  When the nonkeyword form (for example, io-unit) is used for all control-list specifiers in an I/O statement, the io-unit specifier must be the first item in the control list. If a format specifier or namelist group name specifier is used, it must immediately follow the io-unit specifier.
- Mixed form

  When a mix of keyword and nonkeyword forms is used for control-list specifiers in an I/O statement, the nonkeyword values must appear first. Once a keyword form of a specifier is used, all specifiers to the right must also be keyword forms.

Unit Specifier (UNIT=)

The unit specifier identifies the I/O unit to be accessed. It takes the following form:

[UNIT=]*io-unit*

io-unit

For external files, it identifies a logical unit and is one of the following:

- A scalar integer expression that refers to a specific file, I/O device, or pipe. If necessary, the value is converted to integer data type before use. The integer is in the range 0 through 2,147,483,643, equal to the value of one of the constants INPUT_UNIT, OUTPUT_UNIT or ERROR_UNIT from intrinsic module ISO_FORTRAN_ENV, or a value returned by a NEWUNIT= specifier from an OPEN statement.

  Units 5, 6, and 0 are associated with preconnected units.
- An asterisk (*). This is the default (or implicit) external unit, which is preconnected for formatted sequential access. You can also preconnect files by using an environment variable.

For internal files, it identifies a scalar or array character variable that is an internal file. An internal file is designated internal storage space (a variable buffer) that is used with formatted (including list-directed) sequential READ and WRITE statements.

The *io-unit* must be specified in a control list. If the keyword UNIT is omitted, the *io-unit* must be first in the control list.

A unit number is assigned either explicitly through an OPEN statement or implicitly by the system. If a READ statement implicitly opens a file, the file's status is STATUS='OLD'. If a WRITE statement implicitly opens a file, the file's status is STATUS='UNKNOWN'.

If the internal file is a *scalar* character variable, the file has only one record; its length is equal to that of the variable.

If the internal file is an *array* character variable, the file has a record for each element in the array; each record's length is equal to one array element.

An internal file can be read only if the variable has been defined and a value assigned to each record in the file. If the variable representing the internal file is a pointer, it must be associated; if the variable is an allocatable array, it must be currently allocated.

Before data transfer, an internal file is always positioned at the beginning of the first character of the first record.

See Also

OPEN statement

Format Specifier (FMT=)

The format specifier indicates the format to use for data editing. It takes the following form:

[FMT=]*format*

format

Is one of the following:

- The statement label of a FORMAT statement

  The FORMAT statement must be in the same scoping unit as the data transfer statement.
- An asterisk (*), indicating list-directed formatting
- A scalar default integer variable that has been assigned the label of a FORMAT statement (through an ASSIGN statement)

  The FORMAT statement must be in the same scoping unit as the data transfer statement.
- A character expression (which can be an array or character constant) containing the run-time format

  A default character expression must evaluate to a valid format specification. If the expression is an array, it is treated as if all the elements of the array were specified in array element order and were concatenated.
- The name of a numeric array (or array element) containing the format

If the keyword FMT is omitted, the format specifier must be the second specifier in the control list; the io-unit specifier must be first.

If a format specifier appears in a control list, a namelist group specifier must not appear.

See Also

FORMAT statement
Interaction between FORMAT statements and I/O lists
Rules for List-Directed Sequential READ Statements for details on list-directed input
Rules for List-Directed Sequential WRITE Statements for details on list-directed output

Namelist Specifier (NML=)

The namelist specifier indicates namelist formatting and identifies the namelist group for data transfer. It takes the following form:

[NML=]*group*

group

Is the name of a namelist group previously declared in a NAMELIST statement.

If the keyword NML is omitted, the namelist specifier must be the second specifier in the control list; the io-unit specifier must be first.

If a namelist specifier appears in a control list, a format specifier must *not* appear.

See Also

Rules for Namelist Sequential READ Statements for details on namelist input
Rules for Namelist Sequential WRITE Statements for details on namelist output
READ
WRITE

Record Specifier (REC=)

The record specifier identifies the number of the record for data transfer in a file connected for direct access. It takes the following form:

REC=*r*

r — Is a scalar numeric expression indicating the record number. The value of the expression must be greater than or equal to 1, and less than or equal to the maximum number of records allowed in the file.

If necessary, the value is converted to integer data type before use.

If REC is present, no END specifier, * format specifier, or namelist group name can appear in the same control list.

See Also

Alternative Syntax for a Record Specifier

I/O Status Specifier (IOSTAT=)

The I/O status specifier designates a variable to store a value indicating the status of a data transfer operation. It takes the following form:

IOSTAT=*i-var*

i-var — Is a scalar integer variable. When a data transfer statement is executed, *i-var* is set to one of the following values:

A positive integer	Indicating an error condition occurred.
A negative integer	Indicating an end-of-file or end-of-record condition occurred. The negative integers differ depending on which condition occurred.
Zero	Indicating no error, end-of-file, or end-of-record condition occurred.

Execution continues with the statement following the data transfer statement, or the statement identified by a branch specifier (if any).

An end-of-file condition occurs only during execution of a sequential READ statement; an end-of-record condition occurs only during execution of a nonadvancing READ statement.

See Also

List of Run-Time Error Messages
CLOSE
READ
WRITE

Branch Specifiers (END=, EOR=, ERR=)

A branch specifier identifies a branch target statement that receives control if an error, end-of-file, or end-of-record condition occurs. There are three branch specifiers, taking the following forms:

ERR=*label*

END=*label*

EOR=*label*

label — Is the label of the branch target statement that receives control when the specified condition occurs.

The branch target statement must be in the same scoping unit as the data transfer statement.

The following rules apply to these specifiers:

- ERR

  The error specifier can appear in a sequential access READ or WRITE statement, a direct-access READ statement, or a REWRITE statement.

  If an error condition occurs, the position of the file is indeterminate, and execution of the statement terminates.

  If IOSTAT was specified, the IOSTAT variable becomes defined as a positive integer value. If SIZE was specified (in a nonadvancing READ statement), the SIZE variable becomes defined as an integer value. If a *label* was specified, execution continues with the labeled statement.
- END

  The end-of-file specifier can appear only in a sequential access READ statement.

  An end-of-file condition occurs when no more records exist in a file during a sequential read, or when an end-of-file record produced by the ENDFILE statement is encountered. End-of-file conditions do not occur in direct-access READ statements.

  If an end-of-file condition occurs, the file is positioned after the end-of-file record, and execution of the statement terminates.

  If IOSTAT was specified, the IOSTAT variable becomes defined as a negative integer value. If a *label* was specified, execution continues with the labeled statement.
- EOR

  The end-of-record specifier can appear only in a formatted, sequential access READ statement that has the specifier ADVANCE='NO'(nonadvancing input).

  An end-of-record condition occurs when a nonadvancing READ statement tries to transfer data from a position after the end of a record.

  If an end-of-record condition occurs, the file is positioned after the current record, and execution of the statement terminates.

  If IOSTAT was specified, the IOSTAT variable becomes defined as a negative integer value. If PAD='YES' was specified for file connection, the record is padded with blanks (as necessary) to satisfy the input item list and the corresponding data edit descriptor. If SIZE was specified, the SIZE variable becomes defined as an integer value. If a *label* was specified, execution continues with the labeled statement.

If one of the conditions occurs, no branch specifier appears in the control list, but an IOSTAT specifier appears, execution continues with the statement following the I/O statement. If neither a branch specifier nor an IOSTAT specifier appears, the program terminates.

See Also

I/O Status Specifier
Branch Statements

Compiler Reference section: *Error Handling* for details on error processing

Advance Specifier (ADVANCE=)

The advance specifier determines whether nonadvancing I/O occurs for a data transfer statement. It takes the following form:

ADVANCE=*c-expr*

c-expr	Is a scalar character expression that evaluates to 'YES' for advancing I/O or 'NO' for nonadvancing I/O. The default value is 'YES'. Trailing blanks in the expression are ignored. The values specified are without regard to case.

The ADVANCE specifier can appear only in a formatted, sequential data transfer statement that specifies an external unit. It must not be specified for list-directed or namelist data transfer, for a data transfer statement within a DO CONCURRENT block, nor for a data transfer statement within a DO CONCURRENT block.

Advancing I/O always positions a file at the end of a record, unless an error condition occurs. Nonadvancing I/O can position a file at a character position within the current record.

See Also

Compiler Reference: Data and I/O: Fortran I/O: Advancing and Nonadvancing Record I/O

Asynchronous Specifier (ASYNCHRONOUS=)

The asynchronous specifier determines whether asynchronous I/O occurs for a data transfer statement. It takes the following form:

ASYNCHRONOUS=*i-expr*

i-expr
: Is a scalar character constant expression that evaluates to 'YES' for asynchronous I/O or 'NO' for synchronous I/O. The value 'YES' should not appear unless the data transfer statement specifies a file unit number for *io-unit*. The default value is 'NO'.

  Trailing blanks in the expression are ignored. The values specified are without regard to case.

Asynchronous I/O is permitted only for external files opened with an OPEN statement that specifies ASYNCHRONOUS='YES'.

When an asynchronous I/O statement is executed, the pending I/O storage sequence for the data transfer operation is defined to be:

- The set of storage units specified by the I/O item list or by the NML= specifier
- The storage units specified by the SIZE= specifier

Character Count Specifier (SIZE=)

The character count specifier defines a variable to contain the count of the characters transferred by data edit descriptors during execution of the current input statement. It takes the following form:

SIZE=*i-var*

i-var
: Is a scalar integer variable.

If PAD='YES' was specified for file connection, blanks inserted as padding are not counted.

For input statements, the SIZE= specifier can appear only in a formatted, sequential READ statement that has the specifier ADVANCE='NO' (nonadvancing input). It must not be specified for list-directed or namelist data transfer.

For asynchronous nonadvancing input, the storage units specified in the SIZE= specifier become defined with the count of the characters transferred when the corresponding wait operation is executed.

ID Specifier (ID=)

The ID specifier identifies a pending data transfer operation for a specified unit. It takes the following form:

ID=*id-var*

id-var
: Is a scalar integer variable to be used as an identifier.

  This specifier can only be used if the value of ASYNCHRONOUS=*i-expr* is 'YES'.

If an ID specifier is used in a data transfer statement, a wait operation is performed for the operation. If it is omitted, wait operations are performed for all pending data transfers for the specified unit.

If an error occurs during the execution of a data transfer statement containing an ID specifier, the variable specified becomes undefined.

In an INQUIRE statement, the ID= specifier identifies a pending asynchronous data transfer. It is is used with the PENDING specifier to determine whether a specific asynchronous pending data transfer is completed.

POS Specifier (POS=)

The POS specifier identifies the file position in file storage units in a stream file (ACCESS='STREAM'). It takes the following form:

POS=*p*

p	Is a scalar integer expression that specifies the file position. It can only be specified on a file opened for stream access. If omitted, the stream I/O occurs starting at the next file position after the current file position.

Each file storage unit has a unique file position, represented by a positive integer. The first file storage unit is a file is at file position 1. The position of each subsequent file storage unit is one greater than that of its preceding file storage unit.

For a formatted file, the file storage unit is an eight-bit byte. For an unformatted file, the file storage unit is an eight-bit byte (if option assume byterecl is specified) or a 32-bit word (if option assume nobyterecl, the default, is specified).

I/O Message Specifier (IOMSG=)

The I/O message specifier designates a variable to contain the message to be returned when an I/O error occurs. It takes the following form:

IOMSG=*msg-var*

msg-var	Is a scalar default character variable.

If an error (ERR=), end-of-file (END=), or end-of-record (EOR=) condition occurs during execution of an I/O statement, *msg-var* is assigned an explanatory message.

If no error occurs, the value of the variable remains unchanged.

I/O Lists

In a data transfer statement, the I/O list specifies the entities whose values will be transferred. An input list is made up of implied-do lists and simple lists of variables (except for assumed-size arrays). An output list is made up of implied-do lists, expressions, and simple lists of variables (except for assumed-size arrays).

In input statements, the I/O list cannot contain constants and expressions because these do not specify named memory locations that can be referenced later in the program.

However, constants and expressions can appear in the I/O lists for output statements because the compiler can use temporary memory locations to hold these values during the execution of the I/O statement.

If an input item is a pointer, it must be currently associated with a definable target; data is transferred from the file to the associated target. If an output item is a pointer, it must be currently associated with a target; data is transferred from the target to the file.

If an input or output item is an array, it is treated as if the elements (if any) were specified in array element order. For example, if ARRAY_A is an array of shape (2,1), the following input statements are equivalent:

```
READ *, ARRAY_A
READ *, ARRAY_A(1,1), ARRAY_A(2,1)
```

However, no element of that array can affect the value of any expression in the input list, nor can any element appear more than once in an input list. For example, the following input statements are invalid:

```
INTEGER  B(50)
...
READ *, B(B)
READ *, B(B(1):B(10))
```

If an input or output item is an allocatable array, it must be currently allocated.

If an input or output item is a derived type, the following rules apply:

- Any derived-type component must be in the scoping unit containing the I/O statement.
- The derived type must not have a pointer component.
- In a formatted I/O statement, a derived type is treated as if all of the components of the structure were specified in the same order as in the derived-type definition.
- In an unformatted I/O statement, a derived type is treated as a single object.

Simple List Items in I/O Lists
Implied-DO Lists in I/O Lists

Simple List Items in I/O Lists

In a data transfer statement, a simple list of items takes the following form:

item [, *item*] ...

item	Is one of the following: • For input statements: a variable name The variable must not be an assumed-size array, unless one of the following appears in the last dimension: a subscript, a vector subscript, or a section subscript specifying an upper bound. • For output statements: a variable name, expression, or constant Any expression must not attempt further I/O operations on the same logical unit. For example, it must not refer to a function subprogram that performs I/O on the same logical unit.

The data transfer statement assigns values to (or transfers values from) the list items in the order in which the items appear, from left to right.

When multiple array names are used in the I/O list of an unformatted input or output statement, only one record is read or written, regardless of how many array name references appear in the list.

Examples

The following example shows a simple I/O list:

```
WRITE (6,10) J, K(3), 4, (L+4)/2, N
```

When you use an array name reference in an I/O list, an input statement reads enough data to fill every item of the array. An output statement writes all of the values in the array.

Data transfer begins with the initial item of the array and proceeds in the order of subscript progression, with the leftmost subscript varying most rapidly. The following statement defines a two-dimensional array:

```
DIMENSION ARRAY(3,3)
```

If the name ARRAY appears with no subscripts in a READ statement, that statement assigns values from the input record(s) to ARRAY(1,1), ARRAY(2,1), ARRAY(3,1), ARRAY(1,2), and so on through ARRAY(3,3).

An input record contains the following values:

```
1,3,721.73
```

The following example shows how variables in the I/O list can be used in array subscripts later in the list:

```
DIMENSION ARRAY(3,3)
...
READ (1,30) J, K, ARRAY(J,K)
```

When the READ statement is executed, the first input value is assigned to J and the second to K, establishing the subscript values for ARRAY(J,K). The value 721.73 is then assigned to ARRAY(1,3). Note that the variables must appear before their use as array subscripts.

Consider the following derived-type definition and structure declaration:

```
TYPE EMPLOYEE
  INTEGER ID
  CHARACTER(LEN=40) NAME
END TYPE EMPLOYEE
...
TYPE(EMPLOYEE) :: CONTRACT   ! A structure of type EMPLOYEE
```

The following statements are equivalent:

```
READ *, CONTRACT

READ *, CONTRACT%ID, CONTRACT%NAME
```

The following shows more examples:

```
!  A variable and array element in iolist:
      REAL b(99)
      READ (*, 300) n, b(n) ! n and b(n) are the iolist
300   FORMAT (I2, F10.5) ! FORMAT statement telling what form the input data has

!  A derived type and type element in iolist:
      TYPE YOUR_DATA
        REAL a
        CHARACTER(30) info
        COMPLEX cx
      END TYPE YOUR_DATA
      TYPE (YOUR_DATA) yd1, yd2
      yd1.a = 2.3
      yd1.info = "This is a type demo."
      yd1.cx = (3.0, 4.0)
      yd2.cx = (4.5, 6.7)
!  The iolist follows the WRITE (*,500).
      WRITE (*, 500) yd1, yd2.cx
!  The format statement tells how the iolist will be output.
500   FORMAT (F5.3, A21, F5.2, ',', F5.2, ' yd2.cx = (', F5.2,
       ',',F5.2, ' )')
!  The output looks like:
!  2.300This is a type demo 3.00, 4.00 yd2.cx = ( 4.50, 6.70 )
```

The following example uses an array and an array section:

```
!  An array in the iolist:
      INTEGER handle(5)
      DATA handle / 5*0 /
      WRITE (*, 99) handle
99    FORMAT (5I5)
!  An array section in the iolist.
      WRITE (*, 100) handle(2:3)
100   FORMAT (2I5)
```

The following shows another example:

```
PRINT *,'(I5)', 2*3   ! The iolist is the expression 2*3.
```

The following example uses a namelist:

```
! Namelist I/O:
     INTEGER int1
     LOGICAL log1
     REAL r1
     CHARACTER (20) char20
     NAMELIST /mylist/ int1, log1, r1, char20
     int1 = 1
     log1 = .TRUE.
     r1 = 1.0
     char20 = 'NAMELIST demo'
     OPEN (UNIT = 4, FILE = 'MYFILE.DAT', DELIM = 'APOSTROPHE')
     WRITE (UNIT = 4, NML = mylist)
! Writes the following:
! &MYLIST
! INT1 = 1,
! LOG1 = T,
! R1 = 1.000000,
! CHAR20 = 'NAMELIST demo '
! /
     REWIND(4)
     READ (4, mylist)
```

I/O Lists for details on the general rules for I/O lists

Implied-DO Lists in I/O Lists

In a data transfer statement, an implied-DO list acts as though it were a part of an I/O statement within a DO loop. It takes the following form:

(*list*, *do-var* = *expr* 1, *expr* 2 [, *expr* 3])

list	Is a list of variables, expressions, or constants (see Simple List Items in I/O Lists).
do-var	Is the name of a scalar integer or real variable. The variable must not be one of the input items in *list*.
expr	Are scalar numeric expressions of type integer or real. They do not all have to be the same type, or the same type as the DO variable.

The implied-DO loop is initiated, executed, and terminated in the same way as a DO construct.

The *list* is the range of the implied-DO loop. Items in that list can refer to *do-var*, but they must not change the value of *do-var*.

Two nested implied-DO lists must not have the same (or an associated) DO variable.

Use an implied-DO list to do the following:

- Specify iteration of part of an I/O list
- Transfer part of an array
- Transfer array items in a sequence different from the order of subscript progression

If the I/O statement containing an implied-DO list terminates abnormally (with an END, EOR, or ERR branch or with an IOSTAT value other than zero), the DO variable becomes undefined.

Examples

The following two output statements are equivalent:

```
WRITE (3,200) (A,B,C, I=1,3)            ! An implied-DO list

WRITE (3,200) A,B,C,A,B,C,A,B,C         ! A simple item list
```

The following example shows nested implied-DO lists. Execution of the innermost list is repeated most often:

```
WRITE (6,150) ((FORM(K,L), L=1,10), K=1,10,2)
```

The inner DO loop is executed 10 times for each iteration of the outer loop; the second subscript (L) advances from 1 through 10 for each increment of the first subscript (K). This is the reverse of the normal array element order. Note that K is incremented by 2, so only the odd-numbered rows of the array are output.

In the following example, the entire list of the implied-DO list (P(1), Q(1,1), Q(1,2)...,Q(1,10)) are read before I is incremented to 2:

```
READ (5,999) (P(I), (Q(I,J), J=1,10), I=1,5)
```

The following example uses fixed subscripts and subscripts that vary according to the implied-DO list:

```
READ (3,5555) (BOX(1,J), J=1,10)
```

Input values are assigned to BOX(1,1) through BOX(1,10), but other elements of the array are not affected.

The following example shows how a DO variable can be output directly:

```
WRITE (6,1111) (I, I=1,20)
```

Integers 1 through 20 are written.

Consider the following:

```
      INTEGER mydata(25)
      READ (10, 9000) (mydata(I), I=6,10,1)
9000  FORMAT (5I3)
```

In this example, the *iolist* specifies to put the input data into elements 6 through 10 of the array called mydata. The third value in the implied-DO loop, the increment, is optional. If you leave it out, the increment value defaults to 1.

I/O Lists for details on the general rules for I/O lists

Forms for READ Statements

This section discusses the various forms you can specify for READ statements.

Forms for Sequential READ Statements

Sequential READ statements transfer input data from external sequential-access records. The statements can be formatted with format specifiers (which can use list-directed formatting) or namelist specifiers (for namelist formatting), or they can be unformatted.

A sequential READ statement takes one of the following forms:

Formatted:

READ (*eunit*, *format* [, *advance*] [, *asynchronous*] [, *blank*] [, *decimal*] [, *id*] [, *pad*] [, *pos*] [, *round*] [, *size*] [, *iostat*] [, *err*] [, *end*] [, *eor*] [, *iomsg*]) [*io-list*]

READ *form* [, *io-list*]

Formatted - List-Directed:

READ (*eunit*, * [, *asynchronous*] [, *blank*] [, *decimal*] [, *id*] [, *pad*] [, *pos*] [, *round*] [, *iostat*] [, *err*] [, *end*] [, *iomsg*]) [*io-list*]

READ * [, *io-list*]

Formatted - Namelist:

READ (*eunit*, *nml-group* [, *asynchronous*] [, *blank*] [, *decimal*] [, *id*] [, *pad*] [, *pos*] [, *round*] [, *iostat*] [, *err*] [, *end*] [, *iomsg*])

READ *nml*

Unformatted:

READ (*eunit* [, *asynchronous*] [, *id*] [, *pos*] [, *iostat*] [, *err*] [, *end*] [, *iomsg*]) [*io-list*]

READ
I/O control-list specifiers
I/O lists

Rules for Formatted Sequential READ Statements

Formatted, sequential READ statements translate data from character to binary form by using format specifications for editing (if any). The translated data is assigned to the entities in the I/O list in the order in which the entities appear, from left to right.

Values can be transferred to objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred to the components of intrinsic types that ultimately make up these structured objects.

For data transfer, the file must be positioned so that the record read is a formatted record or an end-of-file record.

If the number of I/O list items is *less* than the number of fields in an input record, the statement ignores the excess fields.

If the number of I/O list items is *greater* than the number of fields in an input record, the input record is padded with blanks. However, if PAD='NO' was specified for file connection, the input list and file specification must not require more characters from the record than it contains. If more characters are required and nonadvancing input is in effect, an end-of-record condition occurs.

If the file is connected for unformatted I/O, formatted data transfer is prohibited.

Examples

The following example shows formatted, sequential READ statements:

```
READ (*, '(B)', ADVANCE='NO') C

READ (FMT="(E2.4)", UNIT=6, IOSTAT=IO_STATUS) A, B, C
```

READ statement
Forms for Sequential READ Statements

Rules for List-Directed Sequential READ Statements

List-directed, sequential READ statements translate data from character to binary form by using the data types of the corresponding I/O list item to determine the form of the data. The translated data is then assigned to the entities in the I/O list in the order in which they appear, from left to right.

If a slash (/) is encountered during execution, the READ statement is terminated, and any remaining input list items are unchanged.

If the file is connected for unformatted I/O, list-directed data transfer is prohibited.

List-Directed Records

A list-directed external record consists of a sequence of values and value separators. A value can be any of the following:

- A constant

  Each constant must be a literal constant of type integer, real, complex, logical, or character; or a nondelimited character string. Binary, octal, hexadecimal, Hollerith, and named constants are not permitted.

  In general, the form of the constant must be acceptable for the type of the list item. The data type of the constant determines the data type of the value and the translation from external to internal form. The following rules also apply:

  - A numeric list item can correspond only to a numeric constant, and a character list item can correspond only to a character constant. If the data types of a numeric list element and its corresponding numeric constant do not match, conversion is performed according to the rules for arithmetic assignment (see the table in Numeric Assignment Statements). Conversion is not performed between numeric and logical types unless compiler option `assume old_logical_ldio` is in effect. The decimal point in a numeric constant can either be a period if DECIMAL='POINT' or a comma if DECIMAL='COMMA'.
  - A complex constant has the form of a pair of real or integer constants separated by a comma if DECIMAL='POINT' or a semicolon if DECIMAL='COMMA' and enclosed in parentheses. Blanks can appear between the opening parenthesis and the first constant, before and after the separating comma or semicolon, and between the second constant and the closing parenthesis.
  - A logical constant represents true values (.TRUE. or any value beginning with T, .T, t, or .t) or false values (.FALSE. or any value beginning with F, .F, f, or .f).

  A character string does not need delimiting apostrophes or quotation marks if the corresponding I/O list item is of type default character, and the following is true:

  - The character string does not contain a blank, comma (,), or slash (/).
  - The character string is not continued across a record boundary.
  - The first nonblank character in the string is not an apostrophe or a quotation mark.
  - The leading character is not a string of digits followed by an asterisk.

  A nondelimited character string is terminated by the first blank, comma, slash, or end-of-record encountered. Apostrophes and quotation marks within nondelimited character strings are transferred as is.
- A null value

  A null value is specified by two consecutive value separators (such as,,) or a nonblank initial value separator. (A value separator before the end of the record does not signify a null value.)

  A null value indicates that the corresponding list element remains unchanged. A null value can represent an entire complex constant, but cannot be used for either part of a complex constant.
- A repetition of a null value (r*) or a constant (r*constant), where *r* is an unsigned, nonzero, integer literal constant with no kind parameter, and no embedded blanks.

A value separator is any number of blanks, a slash, or a comma if DECIMAL='POINT' or a semicolon if DECIMAL='COMMA', preceded or followed by any number of blanks. When any of these appear in a character constant, they are considered part of the character constant, not value separators.

The end of a record is equivalent to a blank character, except when it occurs in a character constant. In this case, the end of the record is ignored, and the character constant is continued with the next record (the last character in the previous record is immediately followed by the first character of the next record).

Blanks at the beginning of a record are ignored unless they are part of a character constant continued from the previous record. In this case, the blanks at the beginning of the record are considered part of the constant.

Examples

Suppose the following statements are specified:

```
CHARACTER*14 C
DOUBLE PRECISION T
COMPLEX D,E
LOGICAL L,M
READ (1,*) I,R,D,E,L,M,J,K,S,T,C,A,B
```

Then suppose the following external record is read:

```
4 6.3 (3.4,4.2), (3, 2 ), T,F,,3*14.6,'ABC,DEF/GHI''JK'/
```

The following values are assigned to the I/O list items when DECIMAL='POINT':

I/O List Item	Value Assigned
I	4
R	6.3
D	(3.4,4.2)
E	(3.0,2.0)
L	.TRUE.
M	.FALSE.
J	Unchanged
K	14
S	14.6
T	14.6D0
C	ABC,DEF/GHI' JK
A	Unchanged
B	Unchanged

With DECIMAL='COMMA', the following external record produces the same values as in the table above:

```
4 6,3 (3,4;4,2); (3; 2 ); T;F;;3*14,6,'ABC,DEF/GHI''JK'/
```

The following example shows list-directed input and output:

```
REAL    a
INTEGER i
COMPLEX c
LOGICAL up, down
DATA a /2358.2E-8/, i /91585/, c /(705.60,819.60)/
DATA up /.TRUE./, down /.FALSE./
OPEN (UNIT = 9, FILE = 'listout', STATUS = 'NEW')
WRITE  (9, *) a, i
WRITE  (9, *) c, up, down
REWIND (9)
READ   (9, *) a, i
READ   (9, *) c, up, down
WRITE  (*, *) a, i
WRITE  (*, *) c, up, down
END
```

The preceding program produces the following output:

```
  2.3582001E-05     91585
 (705.6000,819.6000) T F
```

READ

Forms for Sequential READ Statements

Intrinsic Data Types for details on the literal constant forms of intrinsic data types

Rules for List-Directed Sequential WRITE Statements for details on list-directed output

Rules for Namelist Sequential READ Statements

Namelist, sequential READ statements translate data from external to internal form by using the data types of the objects in the corresponding NAMELIST statement to determine the form of the data. The translated data is assigned to objects in the namelist group by specifying the name of the object to which the data is to be assigned.

The order of the object name and data pairs in the input records need not match the order of the objects in the namelist *var-list*. The input need not specify all objects in the namelist *var-list*. They may specify a part of an object more than once. Namelist group names and object names are case insensitive.

If a slash (/) is encountered during execution, the READ statement is terminated, and any remaining input list items are unchanged. An ampersand (&) encountered during input is treated the same as a slash (/).

If the file is connected for unformatted I/O, namelist data transfer is prohibited.

Namelist Records

A namelist external record takes the following form:

&*group-nameobject* = *value* [{, | ;} *object* = *value*] .../

group-name	Is the name of the group containing the objects to be given values. The name must have been previously defined in a NAMELIST statement in the scoping unit. The name cannot contain embedded blanks and must be contained within a single record.

object

Is the name (or subobject designator) of an entity defined in the NAMELIST declaration of the group name. The object name must not contain embedded blanks except within the parentheses of a subscript or substring specifier. Each object must be contained in a single record.

value

Is any of the following:

- A constant

  Each constant must be a literal constant of type integer, real, complex, logical, or character; or a delimited or nondelimited character string. Binary, octal, hexadecimal, Hollerith, and named constants are not permitted.

  In general, the form of the constant must be acceptable for the type of the list item. The data type of the constant determines the data type of the value and the translation from external to internal form. The following rules also apply:

  - A numeric list item can correspond only to a numeric constant, and a character list item can correspond only to a character constant. If the data types of a numeric list element and its corresponding numeric constant do not match, conversion is performed according to the rules for arithmetic assignment (see the table in Numeric Assignment Statements). Logical list items and logical constants are not considered numeric, unless the compiler option `assume old_logical_ldio` is specified. The decimal point in a numeric constant can either be a period if DECIMAL='POINT' or a comma if DECIMAL='COMMA'.
  - A complex constant has the form of a pair of real or integer constants separated by a comma if DECIMAL='POINT' or a semicolon if DECIMAL='COMMA' and enclosed in parentheses. Blanks can appear between the opening parenthesis and the first constant, before and after the separating comma or semicolon, and between the second constant and the closing parenthesis.
  - A logical constant represents true values (.TRUE. or any value beginning with T, .T, t, or .t) or false values (.FALSE. or any value beginning with F, .F, f, or .f).

  Normally, a character string in a NAMELIST statement must be delimited to be read. A delimited string is denoted by apostrophes (DELIM=APOSTROPHE), or quotes (DELIM=QUOTE).

  Intel® Fortran also allows setting DELIM=NONE, which is the default for both input and output. In this case, non-delimited strings are allowed under certain circumstances.

  A character string does not need delimiting apostrophes or quotation marks if the corresponding NAMELIST item is of type default character and it complies with the following rules:

  - The character string cannot contain a blank, tab, equal sign (=), dollar sign ($), slash (/), new line, ampersand (&), or exclamation point(!). A nondelimited character string is terminated if one of these is encountered.

  - Normally, a comma will also cause termination of the nondelimited character string. However, if DECIMAL=COMMA is specified, then the character string cannot contain semicolons but it can contain commas. In this case, if a semicolon is encountered the nondelimited character string is terminated.
- A null value

  A null value is specified by two consecutive value separators (such as two adjacent commas ",,") or a nonblank initial value separator. (A value separator before the end of the record does not signify a null value.)

  A null value indicates that the corresponding list element remains unchanged. A null value can represent an entire complex constant, but cannot be used for either part of a complex constant.
- A repetition of a null value (r*) or a constant (r*constant), where *r* is an unsigned, nonzero, integer literal constant with no kind parameter, and no embedded blanks.

Blanks can precede or follow the beginning ampersand (&), follow the group name, precede or follow the equal sign, or precede the terminating slash.

Comments (beginning with ! only) can appear anywhere in namelist input. The comment extends to the end of the source line.

If an entity appears more than once within the input record for a namelist data transfer, the last value is the one that is used.

If there is more than one *object = value* pair, they must be separated by value separators.

A value separator is any number of blanks, a slash, or a comma if DECIMAL='POINT' or a semicolon if DECIMAL='COMMA', preceded or followed by any number of blanks. When any of these appear in a character constant, they are considered part of the character constant, not value separators.

The end of a record is equivalent to a blank character, except when it occurs in a character constant. In this case, the end of the record is ignored, and the character constant is continued with the next record (the last character in the previous record is immediately followed by the first character of the next record).

Blanks at the beginning of a record are ignored unless they are part of a character constant continued from the previous record. In this case, the blanks at the beginning of the record are considered part of the constant.

When the name in the input record is an array variable or a variable of derived type, the effect is as if the variable represented were expanded into a sequence of scalar list items of intrinsic data types. Each input *value* following the equal sign must comply with format specifications for the intrinsic type of the list item in the corresponding position in the expanded sequence.

The number of values following the equal sign must be equal to or less than the number of list items in the expanded sequence. In the latter case (less than), the effect is as if null values have been added to match any remaining list items in the expanded sequence.

The string length in the NAMELIST statement is not checked against the size of the CHARACTER variable to which it will be assigned. This means that an array of *n* elements written in a NAMELIST statement with DELIM=NONE may not be read back as *n* values. For example, consider a three-element array ARR of three-character elements with values "ABC","DEF","GHI". In DELIM=NONE form, it prints to the data file as follows:

```
ARR = ABCDEFGHI
```

If your program reads that data file, the value will be interpreted as one non-delimited string with the value "ABCDEFGHI" because termination is caused by the trailing blank, tab, or new line.

In some cases, values can be read as more than one string; for example, if the values themselves have final or internal blanks, tabs, or new lines. Consider that ARR contains strings "WX ","Y\tR", "S\nQ", where "\t" is a tab character and "\n" is a newline character. In this case, the data file contains:

```
ARR = WX Y\tRS\nQ
```

The NAMELIST processing will interpret this as four non-delimited strings: "WX", "Y", "RS" and "Q".

NOTE
In NAMELIST declarations, you may get unexpected results if all of the following are true:

1. DELIM=NONE is in effect on input.
2. A character variable is followed by another variable.
3. The other variable is either an array variable that is subscripted or a string variable that is a substring.
4. That subscript or substring expression contains blanks.

In Intel® Fortran, a list of values may follow the equal sign when the object is a single array element. In this case, values are assigned to the specified array element and subsequent elements, in element sequence order. For example, suppose the following input is read:

```
&ELEM
ARRAY_A(3)=34.54, 45.34, 87.63, 3*20.00
/
```

New values are assigned only to array `ARRAY_A` elements 3 through 8. The other element values are unchanged.

Prompting for Namelist Group Information

During execution of a program containing a namelist READ statement, you can specify a question mark character (?) or a question mark character preceded by an equal sign (=?) to get information about the namelist group. The ? or =? must follow one or more blanks.

If specified for a unit capable of both input and output, the ? causes display of the group name and the objects in that group. The =? causes display of the group name, objects within that group, and the current values for those objects (in namelist output form). If specified for another type of unit, the symbols are ignored.

For example, consider the following statements:

```
NAMELIST /NLIST/ A,B,C
REAL A /1.5/
INTEGER B /2/
CHARACTER*5 C /'ABCDE'/
READ (5,NML=NLIST)
WRITE (6,NML=NLIST)
END
```

During execution, if a blank followed by ? is entered on a terminal device, the following values are displayed:

```
&NLIST
   A
   B
   C
/
```

If a blank followed by =? is entered, the following values are displayed:

```
&NLIST
    A  =   1.500000,
    B  =           2,
    C  = ABCDE
/
```

Examples

Suppose the following statements are specified:

```
NAMELIST /CONTROL/ TITLE, RESET, START, STOP, INTERVAL
CHARACTER*10 TITLE
REAL(KIND=8) START, STOP
LOGICAL(KIND=4) RESET
INTEGER(KIND=4) INTERVAL
READ (UNIT=1, NML=CONTROL)
```

The NAMELIST statement associates the group name CONTROL with a list of five objects. The corresponding READ statement reads the following input data from unit 1:

```
 &CONTROL
       TITLE='TESTT002AA',
       INTERVAL=1,
       RESET=.TRUE.,
       START=10.2,
       STOP =14.5
/
```

The following values are assigned to objects in group CONTROL:

Namelist Object	Value Assigned
TITLE	TESTT002AA
RESET	T
START	10.2
STOP	14.5
INTERVAL	1

It is not necessary to assign values to all of the objects declared in the corresponding NAMELIST group. If a namelist object does not appear in the input statement, its value (if any) is unchanged.

Similarly, when character substrings and array elements are specified, only the values of the specified variable substrings and array elements are changed. For example, suppose the following input is read:

```
&CONTROL TITLE(9:10)='BB' /
```

The new value for TITLE is TESTT002BB; only the last two characters in the variable change.

The following example shows an array as an object:

```
DIMENSION ARRAY_A(20)
NAMELIST /ELEM/ ARRAY_A
READ (UNIT=1,NML=ELEM)
```

Suppose the following input is read:

```
&ELEM
ARRAY_A=1.1, 1.2,, 1.4
/
```

The following values are assigned to the ARRAY_A elements:

Array Element	Value Assigned
ARRAY_A(1)	1.1
ARRAY_A(2)	1.2
ARRAY_A(3)	Unchanged
ARRAY_A(4)	1.4
ARRAY_A(5)...ARRAY(20)	Unchanged

Nondelimited character strings that are written out by using a NAMELIST write may not be read in as expected by a corresponding NAMELIST read. Consider the following:

```
NAMELIST/TEST/ CHARR
CHARACTER*3 CHARR(4)
DATA CHARR/'AAA', 'BBB', 'CCC', 'DDD'/
OPEN (UNIT=1, FILE='NMLTEST.DAT')
WRITE (1, NML=TEST)
END
```

The output file NMLTEST.DAT will contain:

```
&TEST CHARR   = AAABBBCCCDDD/
```

If an attempt is then made to read the data in NMLTEST.DAT with a NAMELIST read using nondelimited character strings, as follows:

```
NAMELIST/TEST/ CHARR
CHARACTER*3 CHARR(4)
DATA CHARR/4*'   '/
OPEN (UNIT=1, FILE='NMLTEST.DAT')
READ (1, NML=TEST)
PRINT *, 'CHARR read in >', CHARR(1),'<  >',CHARR(2),'<  >',
1       CHARR(3), '<  >', CHARR(4), '<'
END
```

The result is the following:

```
CHARR read in >AAA<  >   <  >   <  >   <
```

The 12 characters of input were read, truncated to 3 characters, and stored in CHARR(1). The other 3 elements of CHARR were unchanged.

NAMELIST
Alternative Form for Namelist External Records
Rules for Formatted Sequential READ Statements
Rules for Namelist Sequential WRITE Statements

Rules for Unformatted Sequential READ Statements

Unformatted, sequential READ statements transfer binary data (without translation) between the current record and the entities specified in the I/O list. The value transferred from the file is called a field. Only one record is read.

Objects of intrinsic or derived types can be transferred.

For data transfer, the file must be positioned so that the record read is an unformatted record or an end-of-file record.

The unformatted, sequential READ statement reads a single record. Each field value in the record must be of the same type as the corresponding entity in the input list, unless the field value is real or complex.

If the field value is real or complex, one complex field value can correspond to two real list entities, or two real values can correspond to one complex list entity. The corresponding values and entities must have the same kind parameter.

If the number of I/O list items is *less than or equal to* the number of fields in an input record, the READ statement ignores the excess fields. If the number of I/O list items is *greater than* the number of fields in an input record, an error occurs.

If a READ statement contains no I/O list, it skips over one full record, positioning the file to read the following record on the next execution of a READ statement.

If the file is connected for formatted, list-directed, or namelist I/O, unformatted data transfer is prohibited.

You have previously been able to buffer the output (WRITEs) of variable length, unformatted, sequential files, by specifying certain values for an OPEN statement, environment variable, or compiler option. You can now do the same buffering for input (READs) of records. To enable buffering for the input of records, you can specify any of the following:

- BUFFERED=YES in the file's OPEN statement
- Value YES (Y or y), or TRUE (T or t), or a number > 0 for the environment variable FORT_BUFFERED
- Setting `buffered_io` for the `assume` option

When any of the above are specified, the Fortran Runtime Library buffers all input records from variable length, unformatted, sequential files, regardless of the size of the records in the file. In addition, if the environment variable FORT_ BUFFERING_THRESHOLD has a positive value *n*, the following occurs:

- I/O list items with a size <= *n* are buffered and are moved one at a time from the runtime buffer to the I/O list item
- I/O list items with a size > *n* are not buffered and are moved one at a time from the file to the I/O list item

Determining the Size of I/O Buffers

If both the block size and the buffer count have been specified with positive values, their product determines the size in bytes of the buffer for that I/O unit. If neither is specified, the default size of the buffer is 8KB (8192 bytes). This is the initial size of the I/O buffer; the buffer may be expanded to hold a larger record.

If block size is not specified, the following occurs:

- The block size defaults to 128KB
- If the buffer count is not specified, it defaults to 1
- The initial default buffer size is 8KB
- If buffer count is specified, then the initial default buffer size is (8KB * buffercount)

If a block size is specified, the following occurs:

- The block size is the specified value, rounded up to 512-byte boundary
- If the buffer count is not specified, it defaults to 1
- The initial default buffer size is the block size, rounded up to 512-byte boundary
- If buffer count is specified, then the initial default buffer size is (block size * buffer count)

Optimizing for Time or Space

When reading variable length, unformatted sequential records, the runtime system may optimize for time or for space.

This optimization decision is made during runtime on a record-by-record basis using specifications made by the program and the length of a given record. That is, one record may be optimized for time while another record from the same file may be optimized for space.

The default behavior when reading records of this type whose length exceeds the specified block size, is to *not* buffer the input records. You can override this default behavior by requesting that the input be buffered.

The following table shows the relationship between a file's specified block size and the length of its variable length records. Note that the length of the individual record is the key:

	record length >= block size	record length < block size
buffering unspecified	Optimizes for space	Optimizes for time
OPEN (BUFFERED='YES')	Optimizes for time	Optimizes for time
OPEN (BUFFERED='NO')	Optimizes for space	Optimizes for time

If an input record's length is *less than or equal to* the specified block size, then by default, the runtime system always optimizes for time rather than for space and the input is buffered.

If an input record’s length is *greater than* the specified block size, then the following occurs:

- By default, the runtime system always optimizes for space rather than time and the input is not buffered.
- If you request buffering of input, then the runtime system optimizes for time and the input is buffered.
- If you request no buffering of input, then the runtime system optimizes for space rather than time and the input is not buffered.
- If you request dynamic buffering of input, the runtime system optimizes based on the size of the I/O list item and some items are buffered and some are not.

Optimizing for time:

Traditionally, optimizing for time comes at the expense of using more memory.

When the runtime system optimizes for time, it buffers input. It reads as much data as possible during one disk access into the runtime's internal buffer, extending it if necessary to hold the file's largest record. Fields within the record are then moved to the user space in response to READs from the file. Typically, minimizing file accesses is faster.

However, there are circumstances when optimizing for space can actually be faster than optimizing for time.

For example, consider you are reading records whose length exceeds the block size and the data is being read into a contiguous array. Reading this huge array directly into a user's space is going to be faster than reading it first into the runtime system's internal buffer, then moving the data to the user's space. In this case, it is better to optimize for space; that is, you should *not* buffer the input record.

On the other hand, if the READ is being done into non-contiguous elements of an array, the traditional method of optimizing for time becomes a huge win. Data being read into non-contiguous array elements must be moved, or read, into the user's space one element at a time. In this case, you always want to optimize for time; that is, you should buffer the input data.

If you are reading large, variable length, unformatted records, you should try both buffered and unbuffered I/O to determine which delivers the better performance.

Optimizing for space:

Traditionally, optimizing for space comes at the expense of time.

When the runtime system optimizes for space, it wants to avoid creating a huge internal buffer in order to hold a "very large" record. The size of a "very large" record is clearly subjective, but the rule of thumb here is whether or not a record's size is greater than the specified block size.

If this is the case, the runtime system will read one field at a time from the record, directly into the I/O list items. The optimal record for this optimization is one whose record length exceeds the default block size of 128 KB (or a user-specified block size) and contains "very large" fields.

Note that because fields are read one at a time from the file to the user space, very large records that contain very small fields may see a serious performance issue. In these cases, it may be better to buffer the input. If you are reading large, variable length, unformatted records, you should try both buffered and unbuffered I/O to determine which delivers the better performance.

Optimizing unformatted sequential input based on field size - dynamic buffering:

Dynamic buffering is a hybrid solution that chooses the time/space trade-off on a per field basis. The decision is based on a "field size threshold" supplied by the user, deciding, for every field in every record in the file, regardless of the record length, whether or not to buffer a field from the file to the I/O list item. The runtime system can do this because it knows the size of a field that is being requested before actually attempting to read the field.

When a READ statement is first executed, a read from the file is issued to fill the buffer, regardless of its size. This is necessary so that the runtime system can extract the record size from the first length control field. (Each unformatted sequential record has 4-byte leading and trailing record lengths to facilitate reading both forwards and backwards in the file.) From that point on, dynamic buffering decides whether or not to buffer a field or to read it directly from the file to the I/O list item. If the buffer holds the beginning portion of a large field, it will be moved to the start of the I/O list item and the remainder will be read directly from the file.

The following table shows the various buffering options for unformatted, sequential input:

Buffering Option	How do I get this?	What happens?

Non-buffered	You get this kind of buffering by default, or by specifying:
	• OPEN (BUFFERED=NO)
	- or -
	• FORT_BUFFERED=NO
	- or -
	• `assume nobuffered_io`
		When non-buffered is in effect:
		• The runtime system does not re-allocate its buffer to accommodate large records.
		• Records with lengths > the block size:
		  • Are not buffered.
		  • All fields are moved one at a time from the file to the I/O list item.
		• Records with lengths <= the block size:
		  • Are buffered.
		  • All fields are moved one at a time from the buffer to the I/O list item.

Buffered	You get this kind of buffering by specifying: • OPEN (BUFFERED=YES) - or - • FORT_BUFFERED=YES - or -	When buffered is in effect: • The runtime system re-allocates its buffer to accommodate the largest record read. • All input records are buffered.

Buffering Option	How do I get this?	What happens?
	• `assume buffered_io`	• All fields are moved one at a time from the buffer to the I/O list item
Dynamic buffering	You get this kind of buffering by specifying: • FORT_BUFFERING_THRESHOLD=*n* - and one of - • OPEN (BUFFERED=YES) - or - • FORT_BUFFERED=YES - or - • `assume buffered_io`	When dynamic buffering is in effect: • The runtime system does not re-allocate its buffer to accommodate large records. • All fields with a size <= *n* are buffered and are moved one at a time from the buffer to the I/O list item. • Fields with a size > *n* are not buffered and are moved one at a time from the file to the I/O list item.

Examples

The following example shows an unformatted, sequential READ statement:

```
READ (UNIT=6, IOSTAT=IO_STATUS) A, B, C
```

READ statement
Forms for Sequential READ Statements
Record Types

Forms for Direct-Access READ Statements

Direct-access READ statements transfer input data from external records with direct access. (The attributes of a direct-access file are established by the OPEN statement.)

A direct-access READ statement can be formatted or unformatted, and takes one of the following forms:

Formatted:

READ (*eunit*, *format*, *rec* [, *asynchronous*] [, *blank*] [, *decimal*] [, *id*] [, *pad*] [, *pos*] [, *round*] [, *size*] [, *iostat*] [, *err*] [, *iomsg*]) [*io-list*]

Unformatted:

READ (*eunit*, *rec* [, *asynchronous*] [, *id*] [, *pos*] [, *iostat*] [, *err*] [, *iomsg*]) [*io-list*]

See Also

READ
I/O control-list specifiers
I/O lists

Rules for Formatted Direct-Access READ Statements

Formatted, direct-access READ statements translate data from character to binary form by using format specifications for editing (if any). The translated data is assigned to the entities in the I/O list in the order in which the entities appear, from left to right.

Values can be transferred to objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred to the components of intrinsic types that ultimately make up these structured objects.

For data transfer, the file must be positioned so that the record read is a formatted record or an end-of-file record.

If the number of I/O list items is *less* than the number of fields in an input record, the statement ignores the excess fields.

If the number of I/O list items is *greater* than the number of fields in an input record, the input record is padded with blanks. However, if PAD='NO' was specified for file connection, the input list and file specification must not require more characters from the record than it contains. If more characters are required and nonadvancing input is in effect, an end-of-record condition occurs.

If the format specification specifies another record, the record number is increased by one as each subsequent record is read by that input statement.

Examples

The following example shows a formatted, direct-access READ statement:

```
READ (2, REC=35, FMT=10) (NUM(K), K=1,10)
```

Rules for Unformatted Direct-Access READ Statements

Unformatted, direct-access READ statements transfer binary data (without translation) between the current record and the entities specified in the I/O list. Only one record is read.

Objects of intrinsic or derived types can be transferred.

For data transfer, the file must be positioned so that the record read is an unformatted record or an end-of-file record.

The unformatted, direct-access READ statement reads a single record. Each value in the record must be of the same type as the corresponding entity in the input list, unless the value is real or complex.

If the value is real or complex, one complex value can correspond to two real list entities, or two real values can correspond to one complex list entity. The corresponding values and entities must have the same kind parameter.

If the number of I/O list items is less than the number of fields in an input record, the statement ignores the excess fields. If the number of I/O list items is greater than the number of fields in an input record, an error occurs.

If the file is connected for formatted, list-directed, or namelist I/O, unformatted data transfer is prohibited.

Examples

The following example shows unformatted, direct-access READ statements:

```
READ (1, REC=10) LIST(1), LIST(8)
READ (4, REC=58, IOSTAT=K, ERR=500) (RHO(N), N=1,5)
```

Forms for Stream READ Statements

The forms for stream READ statements take the same forms as sequential READ statements. A POS specifier may be present to specify at what file position the READ will start.

You can impose a record structure on a formatted, sequential stream by using a new-line character as a record terminator (see intrinsic function NEW_LINE). There is no record structure in an unformatted, sequential stream.

The INQUIRE statement can be used with the POS specifier to determine the current file position in a stream file.

Examples

The following example shows stream READ statements:

```
READ (12 ) I          !stream reading without POS= specifier
READ (12,POS=10) J    !stream reading with POS= specifier
```

See Also

NEW_LINE

Forms and Rules for Internal READ Statements

Internal READ statements transfer input data from an internal file.

An internal READ statement can only be formatted. It must include format specifiers (which can use list-directed formatting). Namelist formatting is also permitted.

An internal READ statement takes one of the following forms:

READ (*iunit*, *format* [, *nml-group*] [, *iostat*] [, *err*] [, *end*] [, *iomsg*]) [*io-list*]

READ (*iunit*, *nml-group* [, *iostat*] [, *err*] [, *end*] [, *iomsg*]) [*io-list*]

For more information on syntax, see READ.

Formatted, internal READ statements translate data from character to binary form by using format specifications for editing (if any). The translated data is assigned to the entities in the I/O list in the order in which the entities appear, from left to right.

This form of READ statement behaves as if the format begins with a BN edit descriptor. (You can override this behavior by explicitly specifying the BZ edit descriptor.)

Values can be transferred to objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred to the components of intrinsic types that ultimately make up these structured objects.

Before data transfer occurs, the file is positioned at the beginning of the first record. This record becomes the current record.

If the number of I/O list items is *less* than the number of fields in an input record, the statement ignores the excess fields.

If the number of I/O list items is *greater* than the number of fields in an input record, the input record is padded with blanks. However, if PAD='NO' was specified for file connection, the input list and file specification must not require more characters from the record than it contains.

In list-directed and namelist formatting, character strings have no delimiters.

Examples

The following program segment reads a record and examines the first character to determine whether the remaining data should be interpreted as decimal, octal, or hexadecimal. It then uses internal READ statements to make appropriate conversions from character string representations to binary.

```
INTEGER IVAL
CHARACTER TYPE, RECORD*80
CHARACTER*(*) AFMT, IFMT, OFMT, ZFMT
PARAMETER (AFMT='(Q,A)', IFMT= '(I10)', OFMT= '(O11)',        &  ZFMT= '(Z8)')
ACCEPT AFMT, ILEN, RECORD
TYPE = RECORD(1:1)
```

```
IF (TYPE .EQ. 'D') THEN
    READ (RECORD(2:MIN(ILEN, 11)), IFMT) IVAL
ELSE IF (TYPE .EQ. 'O') THEN
    READ (RECORD(2:MIN(ILEN, 12)), OFMT) IVAL
ELSE IF (TYPE .EQ. 'X') THEN
    READ (RECORD(2:MIN(ILEN, 9)),ZFMT) IVAL
ELSE
    PRINT *, 'ERROR'
END IF
END
```

Forms for WRITE Statements

This section discusses the various forms you can specify for WRITE statements.

Forms for Sequential WRITE Statements

Sequential WRITE statements transfer output data to external sequential access records. The statements can be formatted by using format specifiers (which can use list-directed formatting) or namelist specifiers (for namelist formatting), or they can be unformatted.

A sequential WRITE statement takes one of the following forms:

Formatted:

WRITE (*eunit*, *format* [, *advance*] [, *asynchronous*] [, *decimal*] [, *id*] [, *pos*] [, *round*] [, *sign*] [, *iostat*] [, *err*] [, *iomsg*]) [*io-list*]

Formatted - List-Directed:

WRITE (*eunit*, * [, *asynchronous*] [, *decimal*] [, *delim*] [, *id*] [, *pos*] [, *round*] [, *sign*] [, *iostat*] [, *err*] [, *iomsg*]) [*io-list*]

Formatted - Namelist:

WRITE (*eunit*, *nml-group* [, *asynchronous*] [, *decimal*] [, *delim*] [, *id*] [, *pos*] [, *round*] [, *sign*] [, *iostat*] [, *err*] [, *iomsg*])

Unformatted:

WRITE (*eunit* [, *asynchronous*] [, *id*] [, *pos*] [, *iostat*] [, *err*] [, *iomsg*]) [*io-list*]

See Also

WRITE
I/O control-list specifiers
I/O lists

Rules for Formatted Sequential WRITE Statements

Formatted, sequential WRITE statements translate data from binary to character form by using format specifications for editing (if any). The translated data is written to an external file that is connected for sequential access.

Values can be transferred from objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred from the components of intrinsic types that ultimately make up these structured objects.

The output list and format specification must not specify more characters for a record than the record size. (Record size is specified by RECL in an OPEN statement.)

If the file is connected for unformatted I/O, formatted data transfer is prohibited.

Examples

The following example shows formatted, sequential WRITE statements:

```
WRITE (UNIT=8, FMT='(B)', ADVANCE='NO') C

WRITE (*, "(F6.5)", ERR=25, IOSTAT=IO_STATUS) A, B, C
```

See Also

WRITE statement
Forms for Sequential WRITE Statements

Rules for List-Directed Sequential WRITE Statements

List-directed, sequential WRITE statements transfer data from binary to character form by using the data types of the corresponding I/O list item to determine the form of the data. The translated data is then written to an external file.

In general, values transferred as output have the same forms as values transferred as input. However, there is no guarantee that a REAL internal value transferred as output and then transferred as input as a REAL value will be the same internal value.

The following table shows the default output formats for each intrinsic data type:

Default Formats for List-Directed Output

Data Type	Output Format
BYTE	I5
LOGICAL(1)	L2
LOGICAL(2)	L2
LOGICAL(4)	L2
LOGICAL(8)	L2
INTEGER(1)	I5
INTEGER(2)	I7
INTEGER(4)	I12
INTEGER(8)	I22
REAL(4)	1PG15.7E2 [2]
REAL(8)	1PG24.15E3 [2]

Data Type	Output Format
REAL(16)	1PG43.33E4 [2]
COMPLEX(4)	'(',1PG14.7E2,',',1PG14.7E2,')' [2]
COMPLEX(8)	'(',1PG23.15E3,',',1PG23.15E3,')' [2]
COMPLEX(16)	'(',1PG42.33E4,',',1PG42.33E4,')' [2]
CHARACTER	A*w* [1]

[1] Where *w* is the length of the character expression.

[2] If option `assume noold_ldout_format` is in effect, the compiler uses Fortran 2008 standard semantics for output of integer and real values in list-directed and namelist-directed output. This means that for real and complex values, the output is in E or F format depending on the magnitude of the value. For more information, see the description of option assume.

By default, character constants are not delimited by apostrophes or quotation marks, and each internal apostrophe or quotation mark is represented externally by one apostrophe or quotation mark.

This behavior can be changed by the DELIM specifier (in an OPEN statement) as follows:

- If the file is opened with the DELIM='QUOTE' specifier, character constants are delimited by quotation marks and each internal quotation mark is represented externally by two consecutive quotation marks.
- If the file is opened with the DELIM='APOSTROPHE' specifier, character constants are delimited by apostrophes and each internal apostrophe is represented externally by two consecutive apostrophes.

Each output statement writes one or more complete records.

If DECIMAL='POINT', the decimal point in a numeric value is displayed as a period, values are separated by commas, and the separator between the real and imaginary parts of a complex value is a comma. If DECIMAL='COMMA', the decimal point is displayed as a comma, values are separated by semicolons, and the separator between the real and imaginary parts of a complex value is a semicolon.

A literal character constant or complex constant can be longer than an entire record. For complex constants, the end of the record can occur between the comma or semicolon and the imaginary part, if the imaginary part and closing right parenthesis cannot fit in the current record. For literal constants that are longer than an entire record, the constant is continued onto as many records as necessary.

Each output record begins with a blank character for carriage control.

Slashes, octal values, null values, and repeated forms of values are not output.

If the file is connected for unformatted I/O, list-directed data transfer is prohibited.

Examples

Suppose the following statements are specified:

```
DIMENSION A(4)
DATA A/4*3.4/
WRITE (1,*) 'ARRAY VALUES FOLLOW'
WRITE (1,*) A,4
```

The following records are then written to external unit 1:

```
ARRAY VALUES FOLLOW
   3.400000      3.400000      3.400000      3.400000      4
```

The following shows another example:

```
INTEGER       i, j
REAL          a, b
LOGICAL       on, off
```

```
  CHARACTER(20) c
  DATA i /123456/, j /500/, a /28.22/, b /.0015555/
  DATA on /.TRUE./, off/.FALSE./
  DATA c /'Here''s a string'/
  WRITE (*, *)  i, j
  WRITE (*, *)  a, b, on, off
  WRITE (*, *)  c
  END
```

The preceding example produces the following output:

```
    123456         500
  28.22000      1.555500E-03 T F
Here's a string
```

See Also

Rules for Formatted Sequential WRITE Statements
Rules for List-Directed Sequential READ Statements for details on list-directed input

Rules for Namelist Sequential WRITE Statements

Namelist, sequential WRITE statements translate data from internal to external form by using the data types of the objects in the corresponding NAMELIST statement to determine the form of the data. The translated data is then written to an external file.

In general, values transferred as output have the same forms as values transferred as input. However, there is no guarantee that a REAL internal value transferred as output and then transferred as input as a REAL value will be the same internal value.

By default, character constants are not delimited by apostrophes or quotation marks, and each internal apostrophe or quotation mark is represented externally by one apostrophe or quotation mark.

This behavior can be changed by the DELIM specifier (in an OPEN statement) as follows:

- If the file is opened with the DELIM='QUOTE' specifier, character constants are delimited by quotation marks and each internal quotation mark is represented externally by two consecutive quotation marks.
- If the file is opened with the DELIM='APOSTROPHE' specifier, character constants are delimited by apostrophes and each internal apostrophe is represented externally by two consecutive apostrophes.

Each output statement writes one or more complete records.

If DECIMAL='POINT', the decimal point in a numeric value is displayed as a period, values are separated by commas, and the separator between the real and imaginary parts of a complex value is a comma. If DECIMAL='COMMA', the decimal point is displayed as a comma, values are separated by semicolons, and the separator between the real and imaginary parts of a complex value is a semicolon.

A literal character constant or complex constant can be longer than an entire record. For complex constants, the end of the record can occur between the comma or semicolon and the imaginary part, if the imaginary part and closing right parenthesis cannot fit in the current record. For literal constants that are longer than an entire record, the constant is continued onto as many records as necessary.

Each output record begins with a blank character for carriage control, except for literal character constants that are continued from the previous record.

Slashes, octal values, null values, and repeated forms of values are not output.

If the file is connected for unformatted I/O, namelist data transfer is prohibited.

Examples

Consider the following statements:

```
CHARACTER*19 NAME(2)/2*' '/
REAL PITCH, ROLL, YAW, POSITION(3)
LOGICAL DIAGNOSTICS
```

```
INTEGER ITERATIONS
TYPE MYTYPE
   INTEGER X
   REAL Y
   CHARACTER(5)Z
END TYPE MYTYPE
TYPE(MYTYPE) :: TYPEVAR = MYTYPE(1,2.0,'ABCDE')
NAMELIST /PARAM/ NAME, PITCH, ROLL, TYPEVAR, YAW, POSITION,        &
         DIAGNOSTICS, ITERATIONS
...
READ (UNIT=1,NML=PARAM)
WRITE (UNIT=2,NML=PARAM)
```

Suppose the following input is read:

```
&PARAM
    NAME(2)(10:)='HEISENBERG',
    PITCH=5.0, YAW=0.0, ROLL=5.0,
    DIAGNOSTICS=.TRUE.
    ITERATIONS=10
/
```

The following is then written to the file connected to unit 2:

```
&PARAM
NAME    = '                         ', '        HEISENBERG',
PITCH   =    5.000000,
ROLL    =    5.000000,
TYPEVAR = 1, 2.0, 'ABCDE'
YAW     =   0.0000000E+00,
POSITION        = 3*0.0000000E+00,
DIAGNOSTICS     = T,
ITERATIONS      =               10
/
```

Note that character values are not enclosed in apostrophes unless the output file is opened with DELIM='APOSTROPHE'. The value of POSITION is not defined in the namelist input, so the current value of POSITION is written.

The following example declares a number of variables, which are placed in a namelist, initialized, and then written to the screen with namelist I/O:

```
      INTEGER(1) int1
      INTEGER    int2, int3, array(3)
      LOGICAL(1) log1
      LOGICAL log2, log3
      REAL    real1
      REAL(8) real2
      COMPLEX z1, z2
      CHARACTER(1)  char1
      CHARACTER(10) char2

      NAMELIST /example/ int1, int2, int3, log1, log2, log3,       &
     &          real1, real2, z1, z2, char1, char2, array

      int1     = 11
      int2     = 12
      int3     = 14
      log1     = .TRUE.
```

```
      log2     = .TRUE.
      log3     = .TRUE.
      real1    = 24.0
      real2    = 28.0d0
      z1       = (38.0,0.0)
      z2       = (316.0d0,0.0d0)
      char1    = 'A'
      char2    = '0123456789'
      array(1) = 41
      array(2) = 42
      array(3) = 43
      WRITE (*, example)
```

The preceding example produces the following output:

```
&EXAMPLE
INT1  =   11,
INT2  =          12,
INT3  =          14,
LOG1  = T,
LOG2  = T,
LOG3  = T,
REAL1 =   24.00000,
REAL2 =   28.0000000000000,
Z1    = (38.00000,0.0000000E+00),
Z2    = (316.0000,0.0000000E+00),
CHAR1 = A,
CHAR2 = 0123456789,
ARRAY =          41,          42,          43
/
```

NAMELIST
Rules for Formatted Sequential WRITE Statements
Rules for Namelist Sequential READ Statements

Rules for Unformatted Sequential WRITE Statements

Unformatted, sequential WRITE statements transfer binary data (without translation) between the entities specified in the I/O list and the current record. Only one record is written.

Objects of intrinsic or derived types can be transferred.

This form of WRITE statement writes exactly one record. If there is no I/O item list, the statement writes one null record.

If the file is connected for formatted, list-directed, or namelist I/O, unformatted data transfer is prohibited.

For a discussion of I/O buffering, see Rules for Unformatted Sequential READ Statements.

Examples

The following example shows an unformatted, sequential WRITE statement:

```
 WRITE (UNIT=6, IOSTAT=IO_STATUS) A, B, C
```

Forms for Direct-Access WRITE Statements

Direct-access WRITE statements transfer output data to external records with direct access. (The attributes of a direct-access file are established by the OPEN statement.)

A direct-access WRITE statement can be formatted or unformatted, and takes one of the following forms:

Formatted:

WRITE (*eunit*, *format*, *rec* [, *asynchronous*] [, *decimal*] [, *delim*] [, *id*] [, *pos*] [, *round*] [, *sign*] [, *iostat*] [, *err*] [, *iomsg*]) [*io-list*]

Unformatted:

WRITE (*eunit*, *rec* [, *asynchronous*] [, *id*] [, *pos*] [, *iostat*] [, *err*] [, *iomsg*]) [*io-list*]

See Also

WRITE
I/O control-list specifiers
I/O lists

Rules for Formatted Direct-Access WRITE Statements

Formatted, direct-access WRITE statements translate data from binary to character form by using format specifications for editing (if any). The translated data is written to an external file that is connected for direct access.

Values can be transferred from objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred from the components of intrinsic types that ultimately make up these structured objects.

If the values specified by the I/O list do not fill a record, blank characters are added to fill the record. If the I/O list specifies too many characters for the record, an error occurs.

If the format specification specifies another record, the record number is increased by one as each subsequent record is written by that output statement.

Examples

The following example shows a formatted, direct-access WRITE statement:

```
WRITE (2, REC=35, FMT=10) (NUM(K), K=1,10)
```

Rules for Unformatted Direct-Access WRITE Statements

Unformatted, direct-access WRITE statements transfer binary data (without translation) between the entities specified in the I/O list and the current record. Only one record is written.

Objects of intrinsic or derived types can be transferred.

If the values specified by the I/O list do not fill a record, blank characters are added to fill the record. If the I/O list specifies too many characters for the record, an error occurs.

If the file is connected for formatted, list-directed, or namelist I/O, unformatted data transfer is prohibited.

Examples

The following example shows unformatted, direct-access WRITE statements:

```
WRITE (1, REC=10) LIST(1), LIST(8)

WRITE (4, REC=58, IOSTAT=K, ERR=500) (RHO(N), N=1,5)
```

Forms for Stream WRITE Statements

The forms for stream WRITE statements take the same forms as sequential WRITE statements. A POS specifier may be present to specify at what file position the WRITE will start.

After a formatted stream WRITE where no error occurred, the output file is truncated after the byte with the largest POS value. An unformatted stream WRITE does not truncate the output file.

You can impose a record structure on a formatted, sequential stream by using a new-line character as a record terminator (see intrinsic function NEW_LINE). There is no record structure in an unformatted, sequential stream.

The INQUIRE statement can be used with the POS specifier to determine the current file position in a stream file.

See Also

NEW_LINE

Forms and Rules for Internal WRITE Statements

Internal WRITE statements transfer output data to an internal file.

An internal WRITE statement can only be formatted. It must include format specifiers (which can use list-directed formatting). Namelist formatting is also permitted.

An internal WRITE statement takes one of the following forms:

WRITE (*iunit*, *format* [, *iostat*] [, *err*] [, *iomsg*]) [*io-list*]

WRITE (*iunit*, *nml-group* [, *iostat*] [, *err*] [, *iomsg*]) [*io-list*]

For more information on syntax, see WRITE.

Formatted, internal WRITE statements translate data from binary to character form by using format specifications for editing (if any). The translated data is written to an internal file.

Values can be transferred from objects of intrinsic or derived types. For derived types, values of intrinsic types are transferred from the components of intrinsic types that ultimately make up these structured objects.

If the number of characters written in a record is less than the length of the record, the rest of the record is filled with blanks. The number of characters to be written must not exceed the length of the record.

Character constants are not delimited by apostrophes or quotation marks, and each internal apostrophe or quotation mark is represented externally by one apostrophe or quotation mark.

Examples

The following example shows an internal WRITE statement:

```
INTEGER J, K, STAT_VALUE
CHARACTER*50 CHAR_50
...
WRITE (FMT=*, UNIT=CHAR_50, IOSTAT=STAT_VALUE) J, K
```

User-Defined Derived-Type I/O

By default, when a derived-type object is in a formatted I/O statement, it is treated as if all of its components were specified in the component order. The components must be accessible in the scope of the I/O statement and they cannot be pointers or allocatables. In an unformatted I/O statement, a derived-type object is treated as a single value in a processor-dependent form.

User-defined derived-type I/O lets you replace the default I/O processing for a derived-type object. For both unformatted and formatted I/O, a procedures can be invoked that will handle the I/O of the derived type. This is similar to defined operators and defined assignment.

For formatted I/O, the replacement occurs for list-directed formatting, namelist formatting, and for an explicit format with the DT edit descriptor. Other edit descriptors in the explicit format do not have any effect on user-defined I/O.

A procedure can be associated with defined I/O through generic bindings or generic interface blocks. The procedure must conform to the interface that specifies its characteristics. It cannot directly or indirectly use OpenMP* constructs. A defined I/O procedure can also call itself recursively.

An I/O statement that includes a derived-type object and causes a defined I/O procedure to be invoked is called a parent I/O statement. An I/O statement that is executed while a parent statement is being processed, and specifies the unit passed to a defined I/O procedure, is called a child I/O statement.

A defined I/O procedure can be invoked as a parent I/O statement for an external or internal file opened for sequential, direct, or stream access.

This section also has information about how to resolve user-defined I/O procedure references.

Specifying the User-Defined Derived Type

DT Edit Descriptor in User-Defined I/O

The DT edit descriptor passes a character string and integer array to a defined I/O procedure. It takes the following form:

DT [*string*] [(*v-list*)]

The *string* is a default character literal constant delimited by single quotes (' ') or double quotes (" "); no kind parameter can be specified. Its length is the number of characters between the delimiters; two consecutive delimiters are counted as one character. If *string* is not specified, a character string of length zero is passed.

The *v-list* is a list of one or more signed or unsigned integer literal constants; no kind parameter can be specified. If *v-list* is not specified, an integer array of length zero is passed.

A DT edit descriptor must correspond to a list item of a derived type. Also, there should be an accessible interface to a corresponding defined FORMATTED I/O procedure for that derived type.

In a format statement, if the last closing parenthesis of the format string is reached and there are no effective items left, then format processing terminates. But, if there are more items to be processed, then format control reverts to the beginning of the format item which was terminated by the next-to-last right parenthesis.

If there is no such preceding right parenthesis, it reverts to the first left parenthesis of the format specification. During this format reversion, the right parenthesis that is part of a DT edit descriptor is not considered as the next-to-last parenthesis. For example, consider the following:

```
write (10, '(F10.3, I5, 'DT "sample" (1, 2) )' ) 10.1, 3, obj1, 4.7, 1, obj2
```

In the above case, format control reverts to the left parenthesis before F10.3 and not to DT.

Examples

The following are valid ways to specify the DT edit descriptor:

```
DT
DT "z8, i4, e10.2"
DT (1, -1, +1000)
DT 'my type' (0)
```

Associating a Procedure with Defined I/O

Defined I/O Procedures

For a particular derived type and a particular set of kind-type parameter values, there are four possible sets of characteristics for defined I/O procedures: formatted input, formatted output, unformatted input, and unformatted output.

To specify that an I/O procedure should be used for derived-type I/O, specify one of the following with a *defined-io-generic-spec*:

- A generic binding
- An interface block

A *defined-io-generic-spec* is one of the following statements:

- READ (FORMATTED)
- READ (UNFORMATTED)
- WRITE (FORMATTED)
- WRITE (UNFORMATTED)

Generic Bindings

User-defined I/O procedures can be type-bound procedures that use a *defined-io-generic-spec* (see Defined IO Procedures).

Consider the following:

```
TYPE LIST
TYPE(NODE), POINTER :: FIRST
CONTAINS
PROCEDURE :: FMTREAD => LIST_FMTREAD
PROCEDURE :: FMTWRITE => LIST_FMTWRITE
GENERIC,PUBLIC :: READ(FORMATTED) => FMTREAD
GENERIC,PUBLIC :: WRITE(FORMATTED) => FMTWRITE
END TYPE LIST
```

In the above example, LIST_FMTREAD and LIST_FMTWRITE are the type-bound defined I/O procedures. If an object of type LIST is an effective item in a formatted READ statement, LIST_FMTREAD will be called to perform the read operation.

See Also

Type-Bound Procedures
Resolving Defined I/O Procedure References

Generic Interface Block

A generic interface block can be used to associate procedures with defined I/O. The generic identifier should be the *defined-io-generic-spec* (see Defined IO Procedures). This is the only option for sequence or BIND(C) types.

Consider the following:

```
MODULE EXAMPLE

TYPE LIST
INTEGER :: X
END TYPE

INTERFACE READ (FORMATTED)
MODULE PROCEDURE R1
END INTERFACE

CONTAINS
```

```
    SUBROUTINE R1 (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
    CLASS(LIST), INTENT(INOUT) :: DTV
    INTEGER, INTENT(IN) :: UNIT
    CHARACTER(*), INTENT(IN) :: IOTYPE
    INTEGER, INTENT(IN) :: V_LIST(:)
    INTEGER, INTENT(OUT) :: IOSTAT
    CHARACTER(*), INTENT(INOUT) :: IOMSG
       READ (UNIT, FMT=*, IOSTAT=IOSTAT, IOMSG=IOMSG) DTV%X
    END SUBROUTINE R1

END MODULE EXAMPLE
```

In the above example, R1 is the READ (FORMATTED) defined I/O procedure.

If an object of type LIST is an effective item in a formatted READ statement, R1 will be called.

TYPE Statement (Derived Types)
Defining Generic Names for Procedures

Characteristics of Defined I/O Procedures

Shown below are the four interfaces that specify the characteristics of the user-defined I/O procedures. The actual specific procedure names and the names of the dummy arguments in these interfaces are arbitrary.

The following names are used in the interfaces:

dtv-type-spec
: Is one of the following:
  - TYPE(*d-name*) for a sequence or BIND(C) type
  - CLASS(*d-name*) for an extensible type

  d-name is the name of the derived type. It cannot be an abstract type. All length type parameters of the derived type must be assumed.

var
: Is a scalar of the derived type. For output, it holds the value to be written. For input, it will be altered in accordance with the values read.

unit
: Is the scalar integer value of the I/O unit on which input or output is taking place. It is a negative number for an internal file or for an external unit that is a NEWUNIT value. It is a processor-dependent number (which may be negative) for the '*' unit.

iotype
: Is the value 'LISTDIRECTED', 'NAMELIST', or 'DT'//string, where string is the character string from the DT edit descriptor.

vlist
: Is a rank-one assumed-shape integer array whose value comes from the parenthetical list of integers from the DT edit descriptor. For list-directed formatting and namelist formatting, *vlist* is a zero-sized integer array.

iostat
: Is a scalar integer variable that must be given a positive value if an error condition occurs. If an end-of-file or end-of-record condition occurs, it must be given the value IOSTAT_END or IOSTAT_EOR (from the intrinsic module ISO_FORTRAN_ENV). In all other cases, it must be given the value zero.

iomsg	Is an assumed-length scalar character variable that must be set to an explanatory message if iostat is given a nonzero value. Otherwise, it must not be altered.

The following interfaces specify the characteristics of the user-defined I/O procedures:

```
SUBROUTINE my_read_formatted (var,unit,iotype,vlist,iostat,iomsg)
dtv-type-spec,INTENT(INOUT) :: var
INTEGER,INTENT(IN) :: unit
CHARACTER(*),INTENT(IN) :: iotype
INTEGER,INTENT(IN) :: vlist(:)
INTEGER,INTENT(OUT) :: iostat
CHARACTER(*),INTENT(INOUT) :: iomsg
END

SUBROUTINE my_read_unformatted (var,unit,iostat,iomsg)
dtv-type-spec,INTENT(INOUT) :: var
INTEGER,INTENT(IN) :: unit
INTEGER,INTENT(OUT) :: iostat
CHARACTER(*),INTENT(INOUT) :: iomsg
END

SUBROUTINE my_write_formatted (var,unit,iotype,vlist,iostat,iomsg)
dtv-type-spec,INTENT(IN) :: var
INTEGER,INTENT(IN) :: unit
CHARACTER(*),INTENT(IN) :: iotype
INTEGER,INTENT(IN) :: vlist(:)
INTEGER,INTENT(OUT) :: iostat
CHARACTER(*),INTENT(INOUT) :: iomsg
END

SUBROUTINE my_write_unformatted (var,unit,iostat,iomsg)
dtv-type-spec,INTENT(IN) :: var
INTEGER,INTENT(IN) :: unit
INTEGER,INTENT(OUT) :: iostat
CHARACTER(*),INTENT(INOUT) :: iomsg
END
```

ISO_FORTRAN_ENV Module

Defined I/O Data Transfers

The following rules apply to defined I/O data transfers:

- During execution of a defined I/O procedure, there must be no I/O for an external unit except for the unit argument. However, I/O is permitted for internal files.
- You cannot use user-defined I/O in combination with asynchronous I/O.
- No file-positioning commands are permitted in the defined I/O procedure. OPEN, CLOSE, BACKSPACE, ENDFILE, and REWIND statements will not be executed. Any ADVANCE= specifier in a child statement is ignored.
- A record positioning edit descriptor, such as TL and TR, used on the unit by a child data transfer statement will not cause the record position to be positioned before the record position at the time the defined I/O procedure was invoked.
- A child data transfer statement must not specify the ID=, POS=, or REC= specifier in an I/O control list.
- The file position on entry is treated as a left tab limit and there is no record termination on return. However, a child statement with slash (/) edit descriptor, or explicit record termination by a list-directed child I/O, is allowed.

- If the unit is associated with an external file (for example, non-negative, or equal to one of the constants ERROR_UNIT, INPUT_UNIT, or OUTPUT_UNIT from the intrinsic module ISO_FORTRAN_ENV), the current settings for the pad mode, sign mode, etc., can be discovered by using INQUIRE with PAD=, SIGN=, etc. on the unit argument.

  Note that INQUIRE must not be used if the unit is an internal unit passed to a user-defined derived-type I/O procedure from a parent I/O statement. When an internal unit is used with the INQUIRE statement, an error condition will occur, and the variable specified in an IOSTAT= specifier in the INQUIRE statement will be assigned the value IOSTAT_INQUIRE_INTERNAL_UNIT from the intrinsic module ISO_FORTRAN_ENV.

User-Defined Derived-Type I/O

Resolving Defined I/O Procedure References

A generic interface for defined I/O of a derived-type object is one that has both of the following:

- A *defined-io-generic-spec* that is appropriate to the READ or WRITE direction and the form (formatted or unformatted) of the data transfer (see Defined IO Procedures, Generic Bindings, and Generic Interface Block).
- A specific interface whose *var* argument is compatible with the derived-type item.

Within the scope of a *defined-io-generic-spec*, if two procedures have that generic identifier, they must be distinguishable.

For defined I/O procedures, only the *var* argument corresponds to something explicitly written in the program, so it is the *var* that must be distinguishable.

Because *var* arguments are required to be scalar, they cannot differ in rank. So, the *var* must be distinguishable in the type and kind type parameters.

You cannot have two procedures with the same *defined-io-generic-spec*.

See Also

Characteristics of Defined I/O Procedures

Recursive Defined I/O

A defined I/O procedure can invoke itself indirectly.

It can have an I/O statement that includes a derived-type object that results in the invocation of the same procedure. In this case, the defined I/O procedure must be declared RECURSIVE.

Consider the following:

```
! This prints a linked list by calling write on the children
! of the list.

MODULE LIST_MODULE
  IMPLICIT NONE
  TYPE NODE
! This type declaration represents a singly-linked list that also
! contains a user-defined i/o procedure. The name of the procedure
! is arbitrary, but the order of arguments must conform to the
! standard definition.

     INTEGER :: VALUE = -1
     TYPE(NODE), POINTER :: NEXT_NODE => NULL()
   CONTAINS
     PROCEDURE :: PWF
GENERIC :: WRITE(FORMATTED) => PWF ! <=== GENERIC BINDING.
  END TYPE NODE
CONTAINS
```

```
RECURSIVE SUBROUTINE PWF( DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG )
! These arguments are defined in the standard.
    CLASS(NODE), INTENT(IN) :: DTV
    INTEGER, INTENT(IN) :: UNIT
    CHARACTER(LEN=*), INTENT(IN) :: IOTYPE
    INTEGER, DIMENSION(:), INTENT(IN) :: V_LIST
    INTEGER :: IOSTAT
    CHARACTER(LEN=*), INTENT(INOUT) :: IOMSG

! The following is a child i/o statement that is called when user-defined i/o
! statement is invoked.
    WRITE( UNIT=UNIT, FMT='(I9)', IOSTAT=IOSTAT ) DTV%VALUE
    PRINT *, ASSOCIATED(DTV%NEXT_NODE)
    IF(IOSTAT /= 0)RETURN

! It is possible to recursively call the user-defined i/o routine.
    IF(ASSOCIATED(DTV%NEXT_NODE)
      WRITE(UNIT=UNIT, FMT='(/,DT)', IOSTAT=IOSTAT) DTV%NEXT_NODE
    END IF
  END SUBROUTINE PWF
END MODULE LIST_MODULE

PROGRAM LISTE
  USE LIST_MODULE
  IMPLICIT NONE
  INTEGER :: UNIT, IOSTAT, I
  TYPE(NODE), POINTER :: CUR, TO_PRINT

! Create the linked list
  ALLOCATE(CUR)
  CUR % VALUE = 999
  ALLOCATE(TO_PRINT)
  TO_PRINT => CUR

  DO I = 1,10
     ALLOCATE(CUR%NEXT_NODE)
     CUR % VALUE = I
     CUR => CUR%NEXT_NODE
  END DO
  CUR % NEXT_NODE => NULL()
! END CREATION OF LINKED LIST

  DO I = 1,15
     IF(ASSOCIATED(TO_PRINT)) THEN
        PRINT *, I, TO_PRINT%VALUE
        TO_PRINT => TO_PRINT % NEXT_NODE
     END IF
  END DO

! Call the user-defined i/o routine with dt format descriptor.
  WRITE( UNIT=UNIT, FMT='(DT)', IOSTAT=IOSTAT ) CUR
END PROGRAM LISTE
```

RECURSIVE

Examples of User-Defined Derived-Type I/O

Example 1

The following example shows formatted defined I/O using the DT edit descriptor and both generic type-bound and explicit interface procedures:

```
MODULE TYPES
  TYPE T
     INTEGER :: K(10)
   CONTAINS

! a generic type-bound procedure
     PROCEDURE :: UDIO_READ_ARRAY
     GENERIC :: READ (FORMATTED) => UDIO_READ_ARRAY
  END TYPE T

! an explicit interface
  INTERFACE WRITE(FORMATTED)
     MODULE PROCEDURE UDIO_WRITE_ARRAY
  END INTERFACE
 CONTAINS
  SUBROUTINE UDIO_READ_ARRAY (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
    CLASS(T), INTENT(INOUT)     :: DTV
    INTEGER, INTENT(IN)         :: UNIT
    CHARACTER(*), INTENT(IN)    :: IOTYPE
    INTEGER, INTENT(IN)         :: V_LIST (:)
    INTEGER, INTENT(OUT)        :: IOSTAT
    CHARACTER(*), INTENT(INOUT) :: IOMSG

! This is the child I/O that gets performed when the procedure
! is called from a parent I/O - it uses list-directed input to read
! the array K

    READ (UNIT, FMT=*, IOSTAT=IOSTAT, IOMSG=IOMSG) DTV%K

    END SUBROUTINE UDIO_READ_ARRAY

  SUBROUTINE UDIO_WRITE_ARRAY (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
  CLASS(T), INTENT(IN)        :: DTV
  INTEGER, INTENT(IN)         :: UNIT
  CHARACTER(*), INTENT(IN)    :: IOTYPE
  INTEGER, INTENT(IN)         :: V_LIST (:)
  INTEGER, INTENT(OUT)        :: IOSTAT
  CHARACTER(*), INTENT(INOUT) :: IOMSG

! This is the child I/O that gets performed when the procedure
! is called from a parent I/O - it uses list-directed output to write
! the array K

        WRITE (UNIT, FMT=*, IOSTAT=IOSTAT, IOMSG=IOMSG) DTV%K

  END SUBROUTINE UDIO_WRITE_ARRAY

 END MODULE TYPES
```

```
 PROGRAM TEST1
  USE TYPES
  TYPE (T) :: V
  INTEGER  :: COUNTCHAR

   OPEN (1, FILE='TEST.INPUT', FORM='FORMATTED')
    READ (1, FMT='(DT)', ADVANCE='NO', SIZE=COUNTCHAR) V
  CLOSE(UNIT=1)
  WRITE(6, '(DT)') V

 END PROGRAM TEST1
```

Consider that procedure UDIO_READ_ARRAY reads an input file named TEST.INPUT that contains the following:

```
1, 3, 5, 7, 9, 2, 4, 6, 8, 10
```

In this case, the program TEST1 in procedure UDIO_WRITE_ARRAY prints:

```
           1           3           5           7           9           2
           4           6           8          10
```

Example 2

The following example shows list-directed formatted output and user-defined I/O:

```
MODULE M
  TYPE T
     REAL, POINTER :: R (:)
   CONTAINS
     PROCEDURE :: UDIO_WRITE_LD
     GENERIC   :: WRITE(FORMATTED) => UDIO_WRITE_LD
  END TYPE T

CONTAINS
  SUBROUTINE UDIO_WRITE_LD (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
    CLASS(T), INTENT(IN)            :: DTV
    INTEGER, INTENT(IN)             :: UNIT
    CHARACTER(LEN=*), INTENT(IN)    :: IOTYPE
    INTEGER, INTENT(IN)             :: V_LIST (:)
    INTEGER, INTENT(OUT)            :: IOSTAT
    CHARACTER(LEN=*), INTENT(INOUT) :: IOMSG
    IOSTAT = 0
    PRINT *, SIZE (DTV%R)
    WRITE (UNIT, *) DTV%R
  END SUBROUTINE UDIO_WRITE_LD
END MODULE M

PROGRAM TEST2
  USE M
  TYPE (T)     :: X
  REAL, TARGET :: V (3)

  V = [ SIN (1.0), COS (1.0), TAN (1.0) ]
  X = T (R=V)
  PRINT *, X
END PROGRAM TEST2
```

TEST2 should print "`3 0.8414710 0.5403023 1.557408`".

Example 3

The following example shows user-defined derived-type NAMELIST input/output:

```
! PROGRAM: udio_nml_read_write.f90
!
! This program tests NAMELIST READ and WRITE.  In the WRITE subroutine, there
! are FORMATTED WRITES as well as NAMELIST WRITES.
!
MODULE UDIO
  TYPE MYDT
     INTEGER F1
     INTEGER F2
   CONTAINS
     PROCEDURE :: MYSUBROUTINE
     GENERIC :: READ (FORMATTED) => MYSUBROUTINE
  END TYPE MYDT

  INTERFACE WRITE (FORMATTED)
     MODULE PROCEDURE :: WRITESUBROUTINE
  END INTERFACE
CONTAINS

  SUBROUTINE WRITESUBROUTINE (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
    CLASS (MYDT),    INTENT(IN)    :: DTV
    INTEGER*4,         INTENT(IN)    :: UNIT
    CHARACTER (LEN=*),     INTENT(IN)    :: IOTYPE
    INTEGER,              INTENT(IN)    :: V_LIST(:)
    INTEGER*4,         INTENT(OUT)    :: IOSTAT
    CHARACTER (LEN=*),    INTENT(INOUT)    :: IOMSG

    INTEGER I, J
    NAMELIST /SUBRT_NML/ I, J

    I=DTV%F1
    J=DTV%F2

    WRITE (UNIT, '(A,2I5.2)', IOSTAT=IOSTAT) IOTYPE, DTV%F1, DTV%F2
    WRITE (UNIT, NML=SUBRT_NML)
  END SUBROUTINE WRITESUBROUTINE

SUBROUTINE MYSUBROUTINE (DTV, UNIT, IOTYPE, V_LIST, IOSTAT, IOMSG)
    CLASS (MYDT),    INTENT(INOUT)    :: DTV
    INTEGER*4,         INTENT(IN)    :: UNIT
    CHARACTER (LEN=*),     INTENT(IN)    :: IOTYPE
    INTEGER,              INTENT(IN)    :: V_LIST(:)
    INTEGER*4,         INTENT(OUT)    :: IOSTAT
    CHARACTER (LEN=*),    INTENT(INOUT)    :: IOMSG

! X and Y are aliases for DTV%F1 and DTV%F2 since field references
! cannot be referenced in a NAMELIST statement

    INTEGER X, Y
    NAMELIST /SUBRT_NML/ X, Y

    READ (UNIT, *) DTV%F1, DTV%F2
```

```
    X = DTV%F1
    Y = DTV%F2

    READ (UNIT, NML=SUBRT_NML, IOSTAT=IOSTAT)

END SUBROUTINE MYSUBROUTINE

END MODULE UDIO

PROGRAM UDIO_PROGRAM
   USE UDIO
   TYPE (MYDT) :: MYDTV
   INTEGER        :: A, B
   NAMELIST /MAIN_NML/ A, MYDTV, B

   OPEN (10, FILE='udio_nml_read_write.in')
   READ (10, NML=MAIN_NML)
   WRITE (6, NML=MAIN_NML)
   CLOSE (10)

END PROGRAM UDIO_PROGRAM
```

The following shows input file 'udio_nml_read_write.in' on unit 10 read by MYSUBROUTINE:

```
&MAIN_NML
A=100
MYDTV=20 30
&SUBRT_NML
X=20
Y=30
/
/B=200
/
```

The following shows output to unit 6 by WRITESUBROUTINE:

```
&MAIN_NML
 A       =         100,
 MYDTV=NAMELIST   20   30
&SUBRT_NML
 I       =          20,
 J       =          30
/
 /B       =         200
/
```

Example 4

The following example shows user-defined derived-type UNFORMATTED input/output:

```
! PROGRAM: udio_unformatted_1.f90
!
! This test first writes unformatted data to a file via user-defined derived type output
! and then reads the data from the file via user-defined derived type input.
!
MODULE UNFORMATTED
    TYPE UNFORMATTED_TYPE
        INTEGER             :: I
```

```
        CHARACTER*25 :: CHAR
    CONTAINS
        PROCEDURE :: MY_UNFMT_WRITE
        GENERIC :: WRITE (UNFORMATTED) => MY_UNFMT_WRITE
    END TYPE UNFORMATTED_TYPE

    INTERFACE READ (UNFORMATTED)
       MODULE PROCEDURE :: MY_UNFMT_READ
    END INTERFACE

CONTAINS
    SUBROUTINE MY_UNFMT_WRITE (DTV, UNIT, IOSTAT, IOMSG)

```
T T
 T T
```

I/O Formatting

A format appearing in an input or output (I/O) statement specifies the form of data being transferred and the data conversion (editing) required to achieve that form. The format specified can be explicit or implicit.

Explicit format is indicated in a format specification that appears in a FORMAT statement or a character expression (the expression must evaluate to a valid format specification).

The format specification contains edit descriptors, which can be data edit descriptors, control edit descriptors, or string edit descriptors.

Implicit format is determined by the processor and is specified using list-directed or namelist formatting.

List-directed formatting is specified with an asterisk (*); namelist formatting is specified with a namelist group name.

List-directed formatting can be specified for advancing sequential files and internal files. Namelist formatting can be specified only for advancing sequential files.

See Also

Rules for List-Directed Sequential WRITE Statements for details on list-directed output
Rules for Namelist Sequential READ Statements for details on namelist input
Rules for Namelist Sequential WRITE Statements for details on namelist output

Format Specifications

A format specification can appear in a FORMAT statement or a character expression. In a FORMAT statement, it is preceded by the keyword FORMAT. A format specification takes one of the following forms:

([*format-items*])

([*format-items,*] *unlimited-format-item*)

format-items

Is *format-items* [[,] *format-item*]...

where *format-item* is one of the following:

[*r*] *data-edit-desc*
control-edit-desc
char-string-edit-desc
[*r*] (*format-items*)

r

(Optional) Is an integer literal constant. This is called a *repeat specification*. The range of *r* is 1 through 2147483647 (2**31-1). If *r* is omitted, it is assumed to be 1.

data-edit-desc

Is one of the data edit descriptors: I, B, O, Z, F, E, EN, ES, EX, D, DT, G, L, or A.

A repeat specification can precede any data edit descriptor.

control-edit-desc

Is one of the control edit descriptors: T, TL, TR, X, S, SP, SS, BN, BZ, P, :, /, $, \, and Q.

A repeat specification can precede the slash (/) edit descriptor.

char-string-edit-desc

Is one of the string edit descriptors: H, 'c', and "c", where *c* is a character constant.

unlimited-format-item

Is * (*format-items*). The * indicates an unlimited repeat count.

If more than one edit descriptor is specified, they must be separated by commas or slashes (/).

A comma can be omitted in the following cases:

- Between a P edit descriptor and an immediately following F, E, EN, ES, EX, D, or G edit descriptor
- Before a slash (/) edit descriptor when the optional repeat specification is not present
- After a slash (/) edit descriptor
- Before or after a colon (:) edit descriptor

Description

A FORMAT statement must be labeled.

Named constants are not permitted in format specifications.

If the associated I/O statement contains an I/O list, the format specification must contain at least one data edit descriptor or the control edit descriptor Q.

Blank characters can precede the initial left parenthesis, and additional blanks can appear anywhere within the format specification. These blanks have no meaning unless they are within a character string edit descriptor.

When a formatted input statement is executed, the setting of the BLANK specifier (for the relevant logical unit) determines the interpretation of blanks within the specification. If the BN or BZ edit descriptors are specified for a formatted input statement, they supersede the default interpretation of blanks. (For more information on BLANK defaults, see BLANK Specifier in OPEN statements.)

For formatted input, you can use the comma as an external field separator. The comma terminates the input of fields (for noncharacter data types) that are shorter than the number of characters expected. It can also designate null (zero-length) fields.

The following table summarizes the edit descriptors that can be used in format specifications.

Summary of Edit Descriptors

Code	Form	Effect
A	A[w]	Transfers character or Hollerith values.
B	Bw[.m]	Transfers binary values.
BN	BN	Ignores embedded and trailing blanks in a numeric input field.
BZ	BZ	Treats embedded and trailing blanks in a numeric input field as zeros.
D	Dw.d	Transfers real values with D exponents.
DT	DT [string] [(v-list)]	Passes a character string and an integer array to a defined I/O procedure.
E	Ew.d[Ee]	Transfers real values with E exponents.
EN	ENw.d[Ee]	Transfers real values with engineering notation.

Code	Form	Effect
ES	ESw.d[Ee]	Transfers real values with scientific notation.
EX	EXw.d[Ee]	Transfers real values with hexadecimal-significands.
F	Fw.d	Transfers real values with no exponent.
G	Gw.d[Ee]	Transfers values of all intrinsic types.
H	nHch[ch...]	Transfers characters following the H edit descriptor to an output record.
I	Iw[.m]	Transfers decimal integer values.
L	Lw	Transfers logical values: on input, transfers characters; on output, transfers T or F.
O	Ow[.m]	Transfers octal values.
P	kP	Interprets certain real numbers with a specified scale factor.
Q	Q	Returns the number of characters remaining in an input record.
S	S	Reinvokes optional plus sign (+) in numeric output fields; counters the action of SP and SS.
SP	SP	Writes optional plus sign (+) into numeric output fields.
SS	SS	Suppresses optional plus sign (+) in numeric output fields.
T	Tn	Tabs to specified position.
TL	TLn	Tabs left the specified number of positions.
TR	TRn	Tabs right the specified number of positions.
X	nX	Skips the specified number of positions.
Z	Zw[.m]	Transfers hexadecimal values.
$	$	Suppresses trailing carriage return during interactive I/O.
:	:	Terminates format control if there are no more items in the I/O list.

Code	Form	Effect
/	[r]/	Terminates the current record and moves to the next record.
\	\	Continues the same record; same as $.
'c'[1]	'c'	Transfers the character literal constant (between the delimiters) to an output record.

[1] These delimiters can also be quotation marks (").

Character Format Specifications

In data transfer I/O statements, a format specifier ([FMT=]format) can be a character expression that is a character array, character array element, or character constant. This type of format is also called a run-time format because it can be constructed or altered during program execution.

The expression must evaluate to a character string whose leading part is a valid format specification (including the enclosing parentheses).

If the expression is a character array element, the format specification must be contained entirely within that element.

If the expression is a character array, the format specification can continue past the first element into subsequent consecutive elements.

If the expression is a character constant delimited by apostrophes, use two consecutive apostrophes ('') to represent an apostrophe character in the format specification; for example:

```
PRINT '("NUM can''t be a real number")'
```

Similarly, if the expression is a character constant delimited by quotation marks, use two consecutive quotation marks ("") to represent a quotation mark character in the format specification.

To avoid using consecutive apostrophes or quotation marks, you can put the character constant in an I/O list instead of a format specification, as follows:

```
PRINT "(A)", "NUM can't be a real number"
```

The following shows another character format specification:

```
WRITE (6, '(I12, I4, I12)') I, J, K
```

In the following example, the format specification changes with each iteration of the DO loop:

```
SUBROUTINE PRINT(TABLE)
REAL TABLE(10,5)
CHARACTER*5 FORCHR(0:5), RPAR*1, FBIG, FMED, FSML
DATA FORCHR(0),RPAR /'(',')'/
DATA FBIG,FMED,FSML /'F8.2,','F9.4,','F9.6,'/
DO I=1,10
  DO J=1,5
    IF (TABLE(I,J) .GE. 100.) THEN
      FORCHR(J) = FBIG
    ELSE IF (TABLE(I,J) .GT. 0.1) THEN
      FORCHR(J) = FMED
    ELSE
      FORCHR(J) = FSML
    END IF
```

```
  END DO
  FORCHR(5)(5:5) = RPAR
  WRITE (6,FORCHR) (TABLE(I,J), J=1,5)
END DO
END
```

The DATA statement assigns a left parenthesis to character array element FORCHR(0), and (for later use) a right parenthesis and three F edit descriptors to character variables.

Next, the proper F edit descriptors are selected for inclusion in the format specification. The selection is based on the magnitude of the individual elements of array TABLE.

A right parenthesis is added to the format specification just before the WRITE statement uses it.

NOTE
Format specifications stored in arrays are recompiled at run time each time they are used. If a Hollerith or character run-time format is used in a READ statement to read data into the format itself, that data is not copied back into the original array, and the array is unavailable for subsequent use as a run-time format specification.

Examples

The following example shows a format specification:

```
       WRITE (*, 9000) int1, real1(3), char1
9000   FORMAT (I5, 3F4.5, A16)
!  I5, 3F5.2, A16 is the format list.
```

The following shows a format example using a character expression:

```
       WRITE (*, '(I5, 3F5.2, A16)')iolist
!  I5, 3F4.5, A16 is the format list.
```

In the following example, the format list is put into an 80-character variable called MYLIST:

```
CHARACTER(80) MYLIST
MYLIST = '(I5, 3F5.2, A16)'
WRITE (*, MYLIST) iolist
```

Consider the following two-dimensional array:

```
   1  2  3
   4  5  6
```

In this case, the elements are stored in memory in the order: 1, 4, 2, 5, 3, 6 as follows:

```
CHARACTER(6) array(3)
DATA array / '(I5', ',3F5.2', ',A16)' /
WRITE (*, array) iolist
```

In the following example, the WRITE statement uses the character array element array(2) as the format specifier for data transfer:

```
CHARACTER(80) array(5)
array(2) = '(I5, 3F5.2, A16)'
WRITE (*, array(2)) iolist
```

Character string edit descriptors

Data Edit Descriptors

A data edit descriptor causes the transfer or conversion of data to or from its internal representation.

The part of a record that is input or output and formatted with data edit descriptors (or character string edit descriptors) is called a *field*.

Forms for Data Edit Descriptors

A data edit descriptor takes one of the following forms:

[*r*]*c*

[*r*]*cw*

[*r*]*cw.m*

[*r*]*cw.d*

[*r*]*cw.d[Ee]*

r	Is a repeat specification. The range of *r* is 1 through 2147483647 (2**31-1). If *r* is omitted, it is assumed to be 1.
c	Is one of the following format codes: I, B, O, Z, F, E, EN, ES, EX, D, G, L, or A.
w	Is the total number of digits in the field (the field width). If omitted, the system applies default values (see Default Widths for Data Edit Descriptors). The range of *w* is 1 through 2147483647 (2**31-1) on Intel® 64 architecture; 1 through 32767 (2**15-1) on IA-32 architecture. For I, B, O, Z, D, E, EN, ES, EX, F, and G, the range can start at zero.
m	Is the minimum number of digits that must be in the field (including leading zeros). The range of *m* is 0 through 32767 (2**15-1) on Intel® 64 architecture; 0 through 255 (2**8-1) on IA-32 architecture. *w.m* applies to I, B, O, and Z format edit descriptors.
d	Is the number of digits to the right of the decimal point (the significant digits). The range of *d* is 0 through 255. If *d* exceeds 255 at compile time, a warning is issued and the value 255 is used. If *d* exceeds 255 in a run-time format, no warning or error is issued and the value 255 is used. The number of significant digits is affected if a scale factor is specified for the data edit descriptor. For the G edit descriptor, *d* must be specified if *w* is not zero. *w.d* applies to F, E, EN, ES, EX, G, and D format edit descriptors.
E	Identifies an exponent field.
e	Is the number of digits in the exponent. The range of *e* is 0 through 255. If *e* exceeds 255 at compile time, a warning is issued and the value 255 is used. If *e* exceeds 255 in a run-time format, no warning or error is issued and the value 255 is used. For the G edit descriptor, if *w* is zero, *e* must not be specified.

Description

Standard Fortran allows the field width to be omitted only for the A descriptor. However, Intel® Fortran allows the field width to be omitted for any data edit descriptor.

The *r*, *w*, *m*, *d*, and *e* must all be positive, unsigned, integer literal constants, or the digit 0 where allowed, or variable format expressions -- no kind parameter can be specified. They must not be named constants.

Actual useful ranges for *r*, *w*, *m*, *d*, and *e* may be constrained by record sizes (RECL) and the file system.

The data edit descriptors have the following specific forms:

Integer:	Iw[.m], Bw[.m], Ow[.m], and Zw[.m]
Real and complex:	Fw.d, Ew.d[Ee], ENw.d[Ee], ESw.d[Ee], EXw.d[Ee], Dw.d, and Gw.d[Ee]
Logical:	Lw
Character:	A[w]

The *d* must be specified with F, E, EN, ES, EX, D, and G field descriptors even if *d* is zero. The decimal point is also required. You must specify both *w* and *d*.

A repeat specification can simplify formatting. For example, the following two statements are equivalent:

```
20  FORMAT (E12.4,E12.4,E12.4,I5,I5,I5,I5)

20  FORMAT (3E12.4,4I5)
```

Examples

```
!  This WRITE outputs three integers, each in a five-space field
!  and four reals in pairs of F7.2 and F5.2 values.
      INTEGER(2) int1, int2, int3
      REAL(4) r1, r2, r3, r4
      DATA int1, int2, int3 /143, 62, 999/
      DATA r1, r2, r3, r4 /2458.32, 43.78, 664.55, 73.8/
      WRITE (*,9000) int1, int2, int3, r1, r2, r3, r4
9000  FORMAT (3I5, 2(1X, F7.2, 1X, F5.2))
```

The following output is produced from the above code:

```
  143  62  999 2458.32 43.78  664.55 73.80
```

Nested and group repeats

General Rules for Numeric Editing

The following rules apply to input and output data for numeric editing (data edit descriptors I, B, O, Z, F, E, EN, ES, EX, D, and G).

Rules for Input Processing

Leading blanks in the external field are ignored. If the input field is not a hexadecimal-significand number or an IEEE exceptional value, the interpretation of embedded and trailing blanks is determined by the blank interpretation mode. If BLANK='NULL' is in effect (or the BN edit descriptor has been specified) embedded and trailing blanks are ignored; otherwise, they are treated as zeros. An all-blank field is treated as a value of zero.

The following table shows how blanks are interpreted by default:

Type of Unit or File	Default
An explicitly OPENed unit	BLANK='NULL'
An internal file	BLANK='NULL'
A preconnected file[1]	BLANK='NULL'

[1] For interactive input from preconnected files, you should explicitly specify the BN or BZ edit descriptor to ensure desired behavior.

A minus sign must precede a negative value in an external field; a plus sign is optional before a positive value.

In input records, constants can include any valid kind parameter. Named constants are not permitted.

If the data field in a record contains fewer than *w* characters, an input statement will read characters from the next data field in the record. You can prevent this by padding the short field with blanks or zeros, or by using commas to separate the input data. The comma terminates the data field, and can also be used to designate null (zero-length) fields. For more information, see Terminating Short Fields of Input Data.

Rules for Output Processing

The field width *w* must be large enough to include any leading plus or minus sign, and any decimal point or exponent. For example, the field width for an E data edit descriptor must be large enough to contain the following:

- For positive numbers: *d* + 5 or *d* + *e* + 3 characters
- For negative numbers: *d* + 6 or *d* + *e* + 4 characters

For D, E, EN, ES, EX, F, and I edit descriptors, a non-negative value can have a plus sign, depending on which sign edit descriptor is in effect. If a value is negative, the leftmost nonblank character is a minus sign.

If the value is smaller than the field width specified, leading blanks are inserted (the value is right-justified). If the value is too large for the field width specified, the entire output field is filled with asterisks (*).

When the value of the field width is zero, the compiler selects the smallest possible positive actual field width that does not result in the field being filled with asterisks.

Forms for data edit descriptors
Format Specifications

Integer Editing

Integer editing is controlled by the I (decimal), B (binary), O (octal), and Z (hexadecimal) data edit descriptors.

I Editing

The I edit descriptor transfers decimal integer values. It takes the following form:

I*w*[.*m*]

The value of *m* (the minimum number of digits in the constant) must not exceed the value of *w* (the field width), unless *w* is zero. The *m* has no effect on input, only output.

The specified I/O list item must be of type integer; logical and real items are also allowed if the compiler option `check format` is not specified.

The G edit descriptor can be used to edit integer data; it follows the same rules as I*w*.

Rules for Input Processing

On input, the I data edit descriptor transfers *w* characters from an external field and assigns their integer value to the corresponding I/O list item. The external field data must be an integer constant. *w* must not be zero.

If the value exceeds the range of the corresponding input list item, an error occurs.

The following shows input using the I edit descriptor (the symbol ^ represents a nonprinting blank character):

```
Format     Input          Value
I4         2788           2788
I3         -26             -26
I9         ^^^^^^312       312
```

Rules for Output Processing

On output, the I data edit descriptor transfers the value of the corresponding I/O list item, right-justified, to an external field that is *w* characters long.

The field consists of zero or more blanks, followed by a sign (a plus sign is optional for positive values, a minus sign is required for negative values), followed by an unsigned integer constant with no leading zeros.

If *m* is specified, the unsigned integer constant will have at least *m* digits, padded with leading zeros if necessary.

If the output list item has the value zero, and *m* is zero, the external field is filled with blanks; if *w* is also zero, the external field is one blank.

If *w* is zero, the external field has the minimum number of characters necessary to represent the value, left justifying the value with no leading blanks. If both *w* and *m* are zero and the internal value is zero, the external field is one blank.

The following shows output using the I edit descriptor (the symbol ^ represents a nonprinting blank character):

```
Format     Value          Output
I3          284           284
I4         -284           -284
I4             0          ^^^0
I5          174           ^^174
I2         3244           **
I3         -473           ***
I7           29.812       An error; the decimal point is invalid
I4.0          0           ^^^^
I4.2          1           ^^01
I4.4          1           0001
I0         -473           -473
I0.4        242           0242
```

See Also

Forms for data edit descriptors
General rules for numeric editing

B Editing

The B data edit descriptor transfers binary (base 2) values. It takes the following form:

B*w*[.*m*]

The value of *m* (the minimum number of digits in the constant) must not exceed the value of *w* (the field width), unless *w* is zero. The *m* has no effect on input, only output.

The specified I/O list item can be of type integer, real, or logical.

Rules for Input Processing

On input, the B data edit descriptor transfers *w* characters from an external field and assigns their binary value to the corresponding I/O list item. The external field must contain only binary digits (0 or 1) or blanks. *w* must not be zero.

If the value exceeds the range of the corresponding input list item, an error occurs.

The following shows input using the B edit descriptor:

```
Format     Input          Value
B4         1001           9
B1         1              1
B2         ^0             0
B6         ^^^122      An error; the 2 is invalid in binary notation
```

Rules for Output Processing

On output, the B data edit descriptor transfers the binary value of the corresponding I/O list item, right-justified, to an external field that is *w* characters long.

The field consists of zero or more blanks, followed by an unsigned integer constant (consisting of binary digits) with no leading zeros. A negative value is transferred in internal form.

If *w* is zero, the external field has the minimum number of characters necessary to represent the value. If both *w* and *m* are zero and the internal value is zero, the external field is one blank.

If *m* is specified, the unsigned integer constant must have at least *m* digits. If necessary, it is padded with leading zeros.

If *m* is zero, and the output list item has the value zero, the external field is filled with blanks.

The following shows output using the B edit descriptor (the symbol ^ represents a nonprinting blank character):

```
Format       Value         Output
B4            9            1001
B2.2          1            01
B0           42            101010
```

Forms for data edit descriptors
General rules for numeric editing

O Editing

The O data edit descriptor transfers octal (base 8) values. It takes the following form:

O*w*[.*m*]

The value of *m* (the minimum number of digits in the constant) must not exceed the value of *w* (the field width), unless *w* is zero. The *m* has no effect on input, only output.

The specified I/O list item can be of type integer, real, or logical.

Rules for Input Processing

On input, the O data edit descriptor transfers *w* characters from an external field and assigns their octal value to the corresponding I/O list item. The external field must contain only octal digits (0 through 7) or blanks. *w* must not be zero.

If the value exceeds the range of the corresponding input list item, an error occurs.

The following shows input using the O edit descriptor (the symbol ^ represents a nonprinting blank character):

```
Format     Input          Value
O5         77777                32767
O4         77777                 4095
O3         97^           An error; the 9 is invalid in octal notation
```

Rules for Output Processing

On output, the O data edit descriptor transfers the octal value of the corresponding I/O list item, right-justified, to an external field that is *w* characters long.

The field consists of zero or more blanks, followed by an unsigned integer constant (consisting of octal digits) with no leading zeros. A negative value is transferred in internal form without a leading minus sign.

If *w* is zero, the external field has the minimum number of characters necessary to represent the value. If both *w* and *m* are zero and the internal value is zero, the external field is one blank.

If *m* is specified, the unsigned integer constant must have at least *m* digits. If necessary, it is padded with leading zeros.

If *m* is zero, and the output list item has the value zero, the external field is filled with blanks.

The following shows output using the O edit descriptor (the symbol ^ represents a nonprinting blank character):

```
Format      Value          Output
O6           32767         ^77777
O12         -32767         ^37777700001
O2           14261         **
O4              27         ^^33
O5            10.5         41050
O4.2               7       ^^07
O4.4               7       0007
O0                83       123
```

Forms for data edit descriptors
General rules for numeric editing

Z Editing

The Z data edit descriptor transfers hexadecimal (base 16) values. It takes the following form:

Z*w*[.*m*]

The value of *m* (the minimum number of digits in the constant) must not exceed the value of *w* (the field width), unless *w* is zero. The *m* has no effect on input, only output.

The specified I/O list item can be of type integer, real, or logical.

Rules for Input Processing

On input, the Z data edit descriptor transfers *w* characters from an external field and assigns their hexadecimal value to the corresponding I/O list item. The external field must contain only hexadecimal digits (0 though 9 and A (a) through F(f)) or blanks. *w* must not be zero.

If the value exceeds the range of the corresponding input list item, an error occurs.

The following shows input using the Z edit descriptor:

```
Format    Input             Value
Z3        A94                2708
Z5        A23DEF           664542
Z5        95.AF2       An error; the decimal point is invalid
```

Rules for Output Processing

On output, the Z data edit descriptor transfers the hexadecimal value of the corresponding I/O list item, right-justified, to an external field that is *w* characters long.

The field consists of zero or more blanks, followed by an unsigned integer constant (consisting of hexadecimal digits) with no leading zeros. A negative value is transferred in internal form without a leading minus sign.

If *w* is zero, the external field has the minimum number of characters necessary to represent the value. If both *w* and *m* are zero and the internal value is zero, the external field is one blank.

If *m* is specified, the unsigned integer constant must have at least *m* digits. If necessary, it is padded with leading zeros.

If *m* is zero, and the output list item has the value zero, the external field is filled with blanks.

The following shows output using the Z edit descriptor (the symbol ^ represents a nonprinting blank character):

```
Format      Value         Output
Z4           32767        7FFF
Z9          -32767        ^FFFF8001
Z2              16        10
Z4            -10.5       ****
Z3.3           2708       A94
Z6.4           2708       ^^0A94
Z0         14348303        DAF00F
```

Real and Complex Editing

Real and complex editing is controlled by the F, E, D, EN, ES, and EX data edit descriptors. The G, B, O, and Z edit descriptors can also be used to edit real and complex data.

If no field width (*w*) is specified for a real data edit descriptor, the system supplies default values.

Real data edit descriptors can be affected by specified scale factors.

NOTE
Do not use the real data edit descriptors when attempting to parse textual input. These descriptors accept some forms that are purely textual as valid numeric input values. For example, input values T and F are treated as values -1.0 and 0.0, respectively, for .TRUE. and .FALSE.

See Also

Forms for data edit descriptors
General rules for numeric editing
Scale Factor Editing (P)

Default Widths for Data Edit Descriptors for details on system default values for data edit descriptors

F Editing

The F data edit descriptor transfers real values. It takes the following form:

Fw.d

The value of *d* (the number of places after the decimal point) must not exceed the value of *w* (the field width) unless *w* is zero. When *w* is zero, the processor selects the field width. On input, *w* must not be zero.

The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

Rules for Input Processing

On input, the F data edit descriptor transfers *w* characters from an external field and assigns their real value to the corresponding I/O list item. The external field data must be an integer or real constant.

An input field is one of the following:

- An IEEE exception specification
- An hexadecimal-significand number
- An optional sign, followed by a string of one or more digits optionally containing a decimal symbol; any blanks are interpreted as zeros.

The basic form can be followed by an exponent in one of the following forms:

- A sign followed by one or more digits
- An E or D followed by zero or more blanks, followed by an optional sign and one or more digits

An exponent containing a D is processed in the same way as an exponent containing an E.

If the input field contains only an exponent letter or decimal point, it is treated as a zero value.

If the input field does not contain a decimal point or an exponent, it is treated as a real number of *w* digits, with *d* digits to the right of the decimal point. (Leading zeros are added, if necessary.)

If the input field contains a decimal point, the location of that decimal point overrides the location specified by the F descriptor.

If the field contains an exponent, that exponent is used to establish the magnitude of the value before it is assigned to the list element.

An input field that is an IEEE exception specification consists of optional blanks, followed by either of the following:

- An optional sign, followed by the string 'INF' or the string 'INFINITY'; this is an IEEE infinity

  This form can not be used if the processor does not support IEEE infinities for the input variable.
- An optional sign, followed by the string 'NAN', optionally followed by zero or more alphanumeric characters enclosed in parentheses, optionally followed by blanks; this is an IEEE Nan

  This form can not be used if the processor does not support IEEE Nans for the input variable.

The NaN value is a quiet NaN if the only nonblank characters in the field are 'NAN' or 'NAN()'.

An input field that is a hexadecimal-significand number contains an optional sign, followed by the digit 0, followed immediately by the letter X, followed by the hexadecimal significand followed by a hexadecimal exponent. A *hexadecimal significand* is a string of one or more hexadecimal characters, optionally containing a decimal symbol. The position of the hexadecimal point is indicated by the decimal symbol. The hexadecimal point implicitly follows the last hexadecimal character if decimal symbol appears in the string. A hexadecimal exponent is the letter P followed by a signed decimal digit string. Embedded blanks are not allowed; trailing blanks are ignored. The value is equal to the significand multiplied by two raised to the power of the exponent. If the optional sign is a minus, the value is negated.

The following shows input using the F edit descriptor:

```
Format     Input          Value
F8.5       123456789        123.45678
F8.5       -1234.567      -1234.56
F8.5       24.77E+2        2477.0
F5.2       1234567.89       123.45
```

Rules for Output Processing

On output, the F data edit descriptor transfers the real value of the corresponding I/O list item, right-justified and rounded to *d* decimal positions, to an external field that is *w* characters long.

For an internal value that is an IEEE infinity, the output field consists of blanks, if needed, followed by a sign (optional if the value is positive and descriptor SP is not in effect), followed by the letters 'Inf' or 'Infinity', right justified within the field.

If *w* is less than 3, the field is filled with asterisks; otherwise, if *w* is less than 8, 'Inf' is produced.

For an internal value that is an IEEE NaN, the output field consists of blanks, if necessary, followed by the letters 'NaN' and optionally followed by one to *w* − 5 alphanumeric characters enclosed in parentheses, right justified within the field.

If *w* is less than 3, the field is filled with asterisks.

For an internal value that is neither an IEEE infinity nor an IEEE NaN, the *w* must be greater than or equal to *d*+3 to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- At least one digit to the left of the decimal point
- The decimal point
- The *d* digits to the right of the decimal point

A negative value that is not zero but rounds to zero on output is displayed with a leading minus sign. For example, the value -0.00000001 in F5.1 format will be displayed as -0.0 rather than as 0.0. The setting of compiler option assume [no]std_minus0_rounding can affect this behavior.

The following shows output using the F edit descriptor (the symbol ^ represents a nonprinting blank character):

```
Format      Value              Output
F8.5           2.3547188       ^2.35472
F9.3        8789.7361          ^8789.736
F2.1          51.44            **
F10.4        -23.24352         ^^-23.2435
F5.2         325.013           ******
F5.2           -.2             -0.20
```

Forms for data edit descriptors
General rules for numeric editing
assume compiler option

E and D Editing

The E and D data edit descriptors transfer real values in exponential form. They take the following form:

Ew.d[Ee]

Dw.d

where *w* is the total field width, *d* is the number of places after the decimal point, and *e* is the number of digits in the exponent.

For the E edit descriptor, if *w* is zero, the processor selects the field width. If *e* is zero, the exponent part contains the minimum number of digits needed to represent the value of the exponent.

For the D edit descriptor, if the value of *w* is zero, the processor selects the field width.

The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

Rules for Input Processing

On input, the E and D data edit descriptors transfer *w* characters from an external field and assigns their real value to the corresponding I/O list item. The E and D descriptors interpret and assign input data in the same way as the F data edit descriptor. On input, *w* cannot be zero. The *e*, if present, has no effect on input.

The following shows input using the E and D edit descriptors (the symbol ^ represents a nonprinting blank character):

```
Format        Input              Value
E9.3          734.432E3            734432.0
E12.4         ^^1022.43E             1022.43E-6
E15.3         52.3759663^^^^^          52.3759663
E12.5         210.5271D+10         210.5271E10
BZ,D10.2      12345^^^^^         12345000.0D0
D10.2         ^^123.45^^              123.45D0
D15.3         367.4981763D+04           3.674981763D+06
```

If the I/O list item is single-precision real, the E edit descriptor treats the D exponent indicator as an E indicator.

Rules for Output Processing

On output, the E and D data edit descriptors transfer the real value of the corresponding I/O list item, right-justified and rounded to *d* decimal positions, to an external field that is *w* characters long.

If *w* is greater than zero, it should be greater than or equal to *d*+7 to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- An optional zero to the left of the decimal point
- The decimal point
- The *d* digits to the right of the decimal point
- The exponent

The exponent takes one of the following forms:

Edit Descriptor	Absolute Value of Exponent	Positive Form of Exponent	Negative Form of Exponent
Ew.d	|exp| 99	E+nn	E-nn
	99 < |exp| 999	+nnn	-nnn
Ew.dEe	|exp| 10^e - 1	E+$n_1n_2...n_e$	E-$n_1n_2...n_e$
Dw.d	|exp| 99	D+nn or E+nn	D-nn or E-nn
	99 < |exp| 999	+nnn	-nnn

If an exponent exceeds its specified or implied width, or the number of characters produced exceeds the field width, the entire field of width *w* is filled with asterisks.

The exponent field width (*e*) is optional for the E edit descriptor; if omitted, the default value is 2. If *e* is specified, *w* should be greater than or equal to *d*+*e*+5, or zero.

NOTE
If *w* is greater than zero, it can be as small as *d* + 5 or *d* + *e* + 3, if the optional fields for the sign and the zero are omitted.

For an internal value that is an IEEE infinity or an IEEE NaN, the form of the output field is the same as for Fw.d.

A negative value that is not zero but rounds to zero on output is displayed with a leading minus sign. For example, the value -0.01 in "-5P,E20.5" format will be displayed as -0.00 rather than as 0.00. The setting of compiler option assume [no]std_minus0_rounding can affect this behavior.

The following shows output using the E and D edit descriptors (the symbol ^ represents a nonprinting blank character):

```
Format       Value               Output
E11.2        475867.222            ^^^0.48E+06
E11.5        475867.222               0.47587E+06
E12.3             0.00069           ^^^0.690E
E10.3            -0.5555              -0.556E+00
E5.3             56.12               *****
E14.5E4          -1.001              -0.10010E+0001
E13.3E6           0.000123            0.123E-000003
D14.3             0.0363          ^^^^^0.363D-01
D23.12         5413.87625793      ^^^^^0.541387625793D+04
D9.6              1.2             *********
```

EN Editing

The EN data edit descriptor transfers values by using engineering notation. It takes the following form:

ENw.d[Ee]

where *w* is the total field width, *d* is the number of places after the decimal point, and *e* is the number of digits in the exponent.

If *w* is zero, the processor chooses the field width. If *e* is present and zero, the exponent part contains the minimal number of digits needed to represent the exponent .

The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

Rules for Input Processing

On input, the EN data edit descriptor transfers *w* characters from an external field and assigns their real value to the corresponding I/O list item. The EN descriptor interprets and assigns input data in the same way as the F data edit descriptor. *w* cannot be zero on input. *e*, if present, has no effect on input.

The following shows input using the EN edit descriptor (the symbol ^ represents a nonprinting blank character):

```
Format      Input           Value
EN11.3       ^^5.321E+00       5.32100
EN11.3       -600.00E-03       -.60000
EN12.3      ^^^3.150E-03        .00315
EN12.3      ^^^3.829E+03    3829.0
```

Rules for Output Processing

On output, the EN data edit descriptor transfers the real value of the corresponding I/O list item, right-justified and rounded to *d* decimal positions, to an external field that is *w* characters long if *w* is positive. The real value is output in engineering notation, where the decimal exponent is divisible by 3 and the absolute value of the significand is greater than or equal to 1 and less than 1000 (unless the output value is zero).

If *w* is greater than zero, it should be greater than or equal to *d*+9 to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- One to three digits to the left of the decimal point
- The decimal point
- The *d* digits to the right of the decimal point
- The exponent

The exponent takes one of the following forms:

Edit Descriptor	Absolute Value of Exponent	Positive Form of Exponent	Negative Form of Exponent
ENw.d	|exp| 99	E+nn	E-nn
	99 < |exp| 999	+nnn	-nnn
ENw.dEe	|exp| 10^e - 1	E+$n_1n_2...n_e$	E-$n_1n_2...n_e$

If an exponent exceeds its specified or implied width, or the number of characters produced exceeds the field width, the entire field of width *w* is filled with asterisks.

The exponent field width (*e*) is optional; if omitted, the default value is 2. If *e* is specified, *w* should be greater than or equal to *d* + *e* + 5, or zero.

For an internal value that is an IEEE infinity or an IEEE NaN, the form of the output field is the same as for Fw.d.

The following shows output using the EN edit descriptor (the symbol ^ represents a nonprinting blank character):

```
Format     Value          Output
EN11.2     475867.222     ^475.87E+03
EN11.5     475867.222     ***********
EN12.3          0.00069   ^690.000E-06
EN10.3         -0.5555    **********
EN11.2          0.0       ^000.00E-03
```

ES Editing

The ES data edit descriptor transfers values by using scientific notation. It takes the following form:

ESw.d[Ee]

where *w* is the total field width, *d* is the number of places after the decimal point, and *e* is the number of digits in the exponent.

If *w* is zero, the processor selects the field width. If *e* is present and zero, the exponent part contains the minimal number of digits needed to represent the exponent.

The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

Rules for Input Processing

On input, the ES data edit descriptor transfers *w* characters from an external field and assigns their real value to the corresponding I/O list item. The ES descriptor interprets and assigns input data in the same way as the F data edit descriptor. *w* cannot be zero for input. If *e* is present, it has no effect on input.

The following shows input using the ES edit descriptor (the symbol ^ represents a nonprinting blank character):

```
Format     Input           Value
ES11.3      ^^5.321E+00       5.32100
ES11.3       -6.000E-03       -.60000
ES12.3     ^^^3.150E-03        .00315
ES12.3     ^^^3.829E+03    3829.0
```

Rules for Output Processing

On output, the ES data edit descriptor transfers the real value of the corresponding I/O list item, right-justified and rounded to *d* decimal positions, to an external field that is *w* characters long if *w* is positive. The real value is output in scientific notation, where the absolute value of the significand is greater than or equal to 1 and less than 10 (unless the output value is zero).

If w is greater than zero, it should be greater than or equal to *d*+7 to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- One digit to the left of the decimal point
- The decimal point
- The *d* digits to the right of the decimal point
- The exponent

The exponent takes one of the following forms:

Edit Descriptor	Absolute Value of Exponent	Positive Form of Exponent	Negative Form of Exponent
ESw.d	|exp| 99	E+nn	E-nn
	99 < |exp| 999	+nnn	-nnn
ESw.dEe	|exp| 10^e - 1	E+$n_1n_2...n_e$	E-$n_1n_2...n_e$

If an exponent exceeds its specified or implied width, or the number of characters produced exceeds the field width, the entire field of width *w* is filled with asterisks.

The exponent field width (*e*) is optional; if omitted, the default value is 2. If *e* is specified, the *w* should be greater than or equal to *d* + *e* + 5.

For an internal value that is an IEEE infinity or an IEEE NaN, the form of the output field is the same as for Fw.d.

The following shows output using the ES edit descriptor (the symbol ^ represents a nonprinting blank character):

```
Format     Value          Output
ES11.2     473214.356     ^^^4.73E+05
ES11.5     473214.356     4.73214E+05
ES12.3          0.00069   ^^^6.900E-04
ES10.3         -0.5555    -5.555E-01
ES11.2          0.0       ^0.000E+00
```

See Also

Forms for data edit descriptors

General rules for numeric editing

EX Editing

The EX data edit descriptor transfers real values represented as hexadecimal-significand numbers. It takes the following form:

EXw.d[Ee]

w is the external field width, unless it is zero. *d* is the width of the fractional part of the number, unless it is 0.

If *w* or *d* are zero, the processor picks the external field width or the width of the fractional part, respectively. *d* cannot be zero if the radix of the internal value is not a power of two. The hexadecimal point appears after the first hexadecimal digit and it represented by the decimal symbol.

e, if present and nonzero, is the number of digits in the exponent. If E*e* is not present, or *e* is zero, the exponent contains the minimum number of digits needed to represent the exponent. *e* is ignored on input.

The specified I/O list item must be of type real, or it must be the real or imaginary part of a complex type.

Rules for Input Processing

The form and interpretation is the same as that for Fw.d editing.

Rules for Output Processing

The form of the external field for an internal value that is an IEEE infinity or NaN is the same as for Fw.d. Otherwise, it takes the form:

$[+|-]0X_{x0.x1x2...exp}$

where the plus or minus sign is optional, the period signifies the decimal signal, x0x1x2 are the most significant hexadecimal digits after rounding if d is nonzero, and *exp* is the exponent.

For EXw.dEe with *e* greater than zero, the form is $P[+|-]_{z1z2...ze}$. For EXw.d and EXw.dE0, the form of the exponent is $P[+|-]_{z1z2...zn}$ where *n* is the minimum number of digits required to represent the exponent. The exponent sign is always produced and is plus if the exponent is zero. The choice of the binary exponent is processor dependent.

The following shows possible output using the EX edit descriptor if SS is in effect:

```
Format     Value          Output
EX10.2       42.5          0XA.A0P+2
EX0.0E1    6502.0         0XC.B3P+9
EX9.0E2      -0.0         -0X0.P+00
```

F Editing
General rules for numeric editing

G Editing

The G data edit descriptor for generalized editing can be used for input or output with any intrinsic type. It takes the following forms:

G*w*

G*w*.*d*

G*w*.*d*E*e*

where *w* is the total field width, *d* is the number of places after the decimal point, and *e* is the number of digits in the exponent.

If *w* is 0, the field width is selected by the processor. If *w* is zero, you can only specify forms G0 or G0.*d*.

If *w* is nonzero, *d* must be specified.

If *e* is present and zero, the exponent part contains the minimal number of digits needed to represent the exponent. For integer, character, and logical data types *d* and *e* are ignored.

When used to specify I/O for integer data, the G*w*, G*w*.*d* and G*w*.*d*E*e* edit descriptors follow the rules for I*w* editing.

When used to specifiy I/O for logical data, the G*w*.*d* and G*w*.*d*E*e* edit descriptors with nonzero *w* follow the rules for L*w* editing. On output, if *w* is 0, the G*w* and G*w*.*d* edit descriptors follow the rules for L1 editing.

When used to specify I/O for character data, the G*w*.*d* and G*w*.*d*.E*e* edit descriptors with nonzero *w* follows the same rules as A*w* editing. For output, when *w* is zero, the G*w* and G*w*.*d* edit descriptors follow the rules for A editing when no *w* is specified.

Rules for Real Input Processing

On input, the G data edit descriptor transfers *w* characters from an external field and assigns their real value to the corresponding I/O list item. The G descriptor interprets and assigns input data in the same way as the F data edit descriptor. *w* cannot be zero on input. If *e* is present, it has no effect on input.

Rules for Real Output Processing

The form in which the value is written depends on the magnitude of the internal value being edited. N is the magnitude of the internal value and *r* is the rounding mode value defined in the table below. If 0 < N < 0.1 - r x 10^{-d-1} or N >= 10^{d} - r, or N is identically 0, *w* is nonzero, and *d* is 0, G*w*.*d* output editing is the same as k PE*w*.*d* output editing and G*w*.*d* E*e* output editing is the same as k PE*w*.*d* E*e* output editing, where k is the scale factor. If 0.1 - r x 10^{-d-1} <= N < 10^{d} - r or N is identically 0 and *d* is not zero, the scale factor has no effect, and the value of N determines the editing as follows:

Effect of Data Magnitude on G Format Conversions

Data Magnitude	Effective Conversion
N = 0	F(w - n).(d -1), n('b')
0.1 - r x 10^{-d-1} <= N < 1 - r x 10^{-d}	F(w - n).d, n('b')
1 - r x 10^{-d} <= N < 10 - r x 10^{-d+1}	F(w - n).(d -1), n('b')
10 - r x 10^{-d+1} <= N < 100 - r x 10^{-d+2}	F(w - n).(d -2), n('b')
.	.
.	.
.	.
10^{d-2} - r x 10^{-2} <= N < 10^{d-1} - r x 10^{-1}	F(w - n).1, n('b')
10^{d-1} - r x 10^{-1} <= N < 10^{d} - r	(w - n).0, n('b')

The 'b' is a blank following the numeric data representation. For Gw.d, n('b') is 4 blanks. For Gw.dEe, n('b') is *e*+2 blanks.

The *r* is defined for each I/O rounding mode as follows:

Rounding Mode	*r*
COMPATIBLE	0.5
NEAREST	0.5 if the higher value is even -0.5 if the lower value is even
UP	1

Rounding Mode	*r*
DOWN	0
ZERO	1 if the internal value is negative 0 if the internal value is positive

Note that the scale factor has no effect on output unless the magnitude of the datum to be edited is outside the range that permits effective use of F editing.

If *w* is greater than zero, it should be greater than or equal to *d*+7 to allow for the following:

- A sign (optional if the value is positive and descriptor SP is not in effect)
- One digit to the left of the decimal point
- The decimal point
- The *d* digits to the right of the decimal point
- The 4-digit or *e*+2-digit exponent

If *e* is specified and positive, *w* should be greater than or equal to *d* + *e* + 5 if *w* is positive.

If an exponent exceeds its specified or implied width, or the number of characters produced exceeds the field width, the entire field of width *w* is filled with asterisks. However, the field width is not filled with asterisks if the field width is exceeded when optional characters are omitted.

For an internal value that is an IEEE infinity or an IEEE NaN, the form of the output field is the same as for Fw.d.

The following shows output using the G edit descriptor and compares it to output using equivalent F editing (the symbol ^ represents a nonprinting blank character):

```
Value              Format    Output with G     Format    Output with F
       0.01234567  G13.6     ^0.123457E-01     F13.6     ^^^^^0.012346
      -0.12345678  G13.6     -0.123457^^^^     F13.6     ^^^^-0.123457
       1.23456789  G13.6     ^^1.23457^^^^     F13.6     ^^^^^1.234568
      12.34567890  G13.6     ^^12.3457^^^^     F13.6     ^^^^12.345679
     123.45678901  G13.6     ^^123.457^^^^     F13.6     ^^^123.456789
   -1234.56789012  G13.6     ^-1234.57^^^^     F13.6     ^-1234.567890
   12345.67890123  G13.6     ^^12345.7^^^^     F13.6     ^12345.678901
  123456.78901234  G13.6     ^^123457.^^^^     F13.6     123456.789012
-1234567.89012345  G13.6     -0.123457E+07     F13.6     ************
```

If *w* is zero, the G*w* and G*w*.*d* edit descriptors follow the rules for the G.*w*.*d*E*e* edit descriptors on output, but with leading and trailing blanks removed.

Scale Factor Editing (P)

Complex Editing

A complex value is an ordered pair of real values. Complex editing is specified by a pair of real edit descriptors, using any combination of the forms: Fw.d, Ew.d[Ee], Dw.d, ENw.d[Ee], ESw.d[Ee], or Gw.d[Ee].

Rules for Input Processing

On input, the two successive fields are read and assigned to the corresponding complex I/O list item as its real and imaginary part, respectively.

The following shows input using complex editing:

```
Format          Input                Value
F8.5,F8.5       1234567812345.67     123.45678, 12345.67
E9.1,F9.3       734.432E8123456789   734.432E8, 123456.789
```

Rules for Output Processing

On output, the two parts of the complex value are transferred under the control of repeated or successive real edit descriptors. The two parts are transferred consecutively without punctuation or blanks, unless control or character string edit descriptors are specified between the pair of real edit descriptors.

The following shows output using complex editing (the symbol ^ represents a nonprinting blank character):

```
Format              Value                  Output
2F8.5               2.3547188, 3.456732    ^2.35472 ^3.45673
E9.2,'^,^',E5.3     47587.222, 56.123      ^0.48E+06^,^*****
```

Forms for data edit descriptors
General rules for numeric editing
General Rules for Complex Constants for details on complex constants

Logical Editing (L)

The L data edit descriptor transfers logical values. It takes the following form:

Lw

The specified I/O list item must be of type logical or integer.

The G edit descriptor can be used to edit logical data; it follows the same rules as L*w*.

Rules for Input Processing

On input, the L data edit descriptor transfers *w* characters from an external field and assigns their logical value to the corresponding I/O list item. The value assigned depends on the external field data, as follows:

- .TRUE. is assigned if the first nonblank character is .T, T, .t, or t. The logical constant .TRUE. is an acceptable input form.
- .FALSE. is assigned if the first nonblank character is .F, F. .f, or f, or the entire field is filled with blanks. The logical constant .FALSE. is an acceptable input form.

If an other value appears in the external field, an error occurs.

Rules for Output Processing

On output, the L data edit descriptor transfers the following to an external field that is *w* characters long: w - 1 blanks, followed by a T or F (if the value is .TRUE. or .FALSE., respectively).

The following shows output using the L edit descriptor (the symbol ^ represents a nonprinting blank character):

```
Format      Value          Output
L5          .TRUE.         ^^^^T
L1          .FALSE.        F
```

See Also

Forms for data edit descriptors

Character Editing (A)

The A data edit descriptor transfers character or Hollerith values. It takes the following form:

A[w]

If the corresponding I/O list item is of type character, character data is transferred. If the list item is of any other type, Hollerith data is transferred.

The G edit descriptor can be used to edit character data; it follows the same rules as A*w*.

Rules for Input Processing

On input, the A data edit descriptor transfers *w* characters from an external field and assigns them to the corresponding I/O list item.

The maximum number of characters that can be stored depends on the size of the I/O list item, as follows:

- For character data, the maximum size is the length of the corresponding I/O list item.
- For noncharacter data, the maximum size depends on the data type, as shown in the following table:

Size Limits for Noncharacter Data Using A Editing

I/O List Element	Maximum Number of Characters
BYTE	1
LOGICAL(1) or LOGICAL*1	1
LOGICAL(2) or LOGICAL*2	2
LOGICAL(4) or LOGICAL*4	4
LOGICAL(8) or LOGICAL*8	8
INTEGER(1) or INTEGER*1	1
INTEGER(2) or INTEGER*2	2
INTEGER(4) or INTEGER*4	4
INTEGER(8) or INTEGER*8	8
REAL(4) or REAL*4	4
DOUBLE PRECISION	8
REAL(8) or REAL*8	8
REAL(16) or REAL*16	16
COMPLEX(4) or COMPLEX*8[1]	8
DOUBLE COMPLEX[1]	16
COMPLEX(8) or COMPLEX*16[1]	16
COMPLEX(16) or COMPLEX*32[1]	32

[1] Complex values are treated as pairs of real numbers, so complex editing requires a pair of edit descriptors. (See Complex Editing.)

If *w* is equal to or greater than the length (*len*) of the input item, the rightmost characters are assigned to that item. The leftmost excess characters are ignored.

If *w* is less than *len*, or less than the number of characters that can be stored, *w* characters are assigned to the list item, left-justified, and followed by trailing blanks.

The following shows input using the A edit descriptor (the symbol ^ represents a nonprinting blank character):

```
Format      Input       Value          Data Type
A6          PAGE^#      #              CHARACTER(LEN=1)
A6          PAGE^#      E^#            CHARACTER(LEN=3)
A6          PAGE^#      PAGE^#         CHARACTER(LEN=6)
A6          PAGE^#      PAGE^#^^       CHARACTER(LEN=8)
A6          PAGE^#      #              LOGICAL(1)
A6          PAGE^#      ^#             INTEGER(2)
A6          PAGE^#      GE^#           REAL(4)
A6          PAGE^#      PAGE^#^^       REAL(8)
```

Rules for Output Processing

On output, the A data edit descriptor transfers the contents of the corresponding I/O list item to an external field that is *w* characters long.

If *w* is greater than the size of the list item, the data is transferred to the output field, right-justified, with leading blanks. If *w* is less than or equal to the size of the list item, the leftmost *w* characters are transferred.

The following shows output using the A edit descriptor (the symbol ^ represents a nonprinting blank character):

```
Format      Value          Output
A5          OHMS           ^OHMS
A5          VOLTS          VOLTS
A5          AMPERES        AMPER
```

See Also

Forms for data edit descriptors

Defined I/O Editing (DT)

The DT edit descriptor passes a character string and integer array to a defined I/O procedure. It takes the following form:

DT [*string*] [(*v-list*)]

For more information on this edit descriptor, see DT Edit Descriptor in User-Defined I/O.

Default Widths for Data Edit Descriptors

If *w* (the field width) is omitted for the data edit descriptors, the system applies default values. For the real data edit descriptors, the system also applies default values for *d* (the number of characters to the right of the decimal point), and *e* (the number of characters in the exponent).

These defaults are based on the data type of the I/O list item, and are listed in the following table:

Default Widths for Data Edit Descriptors

Edit Descriptor	Data Type of I/O List Item	w
I, B, O, Z, G	BYTE	7

Edit Descriptor	Data Type of I/O List Item	w
	INTEGER(1), LOGICAL(1)	7
	INTEGER(2), LOGICAL(2)	7
	INTEGER(4), LOGICAL(4)	12
	INTEGER(8), LOGICAL(8)	23
O, Z	REAL(4)	12
	REAL(8)	23
	REAL(16)	44
	CHARACTER*len	MAX(7, 3*len)
L, G	LOGICAL(1), LOGICAL(2), LOGICAL(4), LOGICAL(8)	2
F, E, ES, G, D	REAL(4), COMPLEX(4)	15 **d**: 7 **e**: 2
	REAL(8), COMPLEX(8)	25 **d**: 16 **e**: 2
	REAL(16), COMPLEX(16)	42 **d**: 33 **e**: 3
EN	REAL(4), COMPLEX(4)	15 **d**: 6 **e**: 2
	REAL(8), COMPLEX(8)	25 **d**: 16 **e**: 2
	REAL(16), COMPLEX(16)	42 **d**: 32 **e**: 3
A[1], G	LOGICAL(1)	1
	LOGICAL(2), INTEGER(2)	2
	LOGICAL(4), INTEGER(4)	4
	LOGICAL(8), INTEGER(8)	8
	REAL(4), COMPLEX(4)	4
	REAL(8), COMPLEX(8)	8
	REAL(16), COMPLEX(16)	16
	CHARACTER*len	len

[1] The default is the actual length of the corresponding I/O list item.

Terminating Short Fields of Input Data

On input, an edit descriptor such as Fw.d specifies that *w* characters (the field width) are to be read from the external field.

If the field contains fewer than *w* characters, the input statement will read characters from the next data field in the record. You can prevent this by padding the short field with blanks or zeros, or by using commas to separate the input data.

Padding Short Fields

You can use the OPEN statement specifier PAD='YES' to indicate blank padding for short fields of input data. However, blanks can be interpreted as blanks *or* zeros, depending on which default behavior is in effect at the time. Consider the following:

```
READ (2, '(I5)') J
```

If 3 is input for J, the value of J will be 30000 or 3 depending on which default behavior is in effect (BLANK='NULL' or BLANK='ZERO'). This can give unexpected results.

To ensure that the desired behavior is in effect, explicitly specify the BN or BZ edit descriptor. For example, the following ensures that blanks are interpreted as blanks (and not as zeros):

```
READ (2, '(BN, I5)') J
```

Using Commas to Separate Input Data

You can use a comma to terminate a short data field. The comma has no effect on the *d* part (the number of characters to the right of the decimal point) of the specification.

The comma overrides the *w* specified for the I, B, O, Z, F, E, D, EN, ES, G, and L edit descriptors. For example, suppose the following statements are executed:

```
      READ (5,100) I,J,A,B
100   FORMAT (2I6,2F10.2)
```

Suppose a record containing the following values is read:

```
1, -2, 1.0, 35
```

The following assignments occur:

```
I = 1
J = -2
A = 1.0
B = 0.35
```

A comma can only terminate fields less than *w* characters long. If a comma follows a field of *w* or more characters, the comma is considered part of the next field.

A null (zero-length) field is designated by two successive commas, or by a comma after a field of *w* characters. Depending on the field descriptor specified, the resulting value assigned is 0, 0.0, 0.0D0, 0.0Q0, or .FALSE..

General Rules for Numeric Editing

Control Edit Descriptors

A control edit descriptor either directly determines how text is displayed or affects the conversions performed by subsequent data edit descriptors.

Forms for Control Edit Descriptors

A control edit descriptor takes one of the following forms:

c

cn

nc

c	Is one of the following format codes: T, TL, TR, X, S, SP, SS, BN, BZ, P, RU, RD, RZ, RN, RC, RP, DC, DP, :, /, \, $, and Q.
n	Is a number of character positions. It must be a positive integer literal constant or a variable format expression. No kind parameter can be specified. It cannot be a named constant. The range of *n* is 1 through 2147483647 (2**31-1) on Intel® 64 architecture; 1 through 32767 (2**15-1) on IA-32 architecture. Actual useful ranges may be constrained by record sizes (RECL) and the file system.

Description

In general, control edit descriptors are nonrepeatable. The only exception is the slash (/) edit descriptor, which can be preceded by a repeat specification or a * indicating an unlimited repeat count.

The control edit descriptors have the following specific forms:

Positional:	Tn, TLn, TRn, and nX
Sign:	S, SP, and SS
Blank interpretation:	BN and BZ
Rounding mode:	RU, RD, RZ, RN, RC, and RP
Decimal mode:	DC and DP
Scale factor:	kP
Miscellaneous:	:, /, \, $, and Q

The P edit descriptor is an exception to the general control edit descriptor syntax. It is preceded by a scale factor, rather than a character position specifier.

Control edit descriptors can be grouped in parentheses and preceded by a group repeat specification.

See Also

Group repeat specifications
Format Specifications

Positional Editing

The T, TL, TR, and X edit descriptors specify the position where the next character is transferred to or from a record.

On output, these descriptors do not themselves cause characters to be transferred and do not affect the length of the record. If characters are transferred to positions at or after the position specified by one of these descriptors, positions skipped and not previously filled are filled with blanks. The result is as if the entire record was initially filled with blanks.

The TR and X edit descriptors produce the same results.

See Also

Forms for Control Edit Descriptors

T Editing

The T edit descriptor specifies a character position in an I/O record. It takes the following form:

Tn

The *n* is a positive integer literal constant (with no kind parameter) indicating the character position of the record, relative to the left tab limit.

On input, the T descriptor positions the external record at the character position specified by *n*. On output, the T descriptor indicates that data transfer begins at the *n*th character position of the external record.

Examples

In the following examples, the symbol ^ represents a nonprinting blank character.

Suppose a file has a record containing the value `ABC^^^XYZ`, and the following statements are executed:

```
      READ (11,10) VALUE1, VALUE2
 10   FORMAT (T7,A3,T1,A3)
```

The values read first are XYZ, then ABC.

Suppose the following statements are executed:

```
     PRINT 25
25   FORMAT (T51,'COLUMN 2',T21,'COLUMN 1')
```

The following line is printed at the positions indicated:

```
Position 20                    Position 50
   |                              |
   COLUMN 1                       COLUMN 2
```

Note that the first character of the record printed was reserved as a control character.

See Also

Printing of Formatted Records

TL Editing

The TL edit descriptor specifies a character position to the *left* of the current position in an I/O record. It takes the following form:

TLn

The *n* is a positive integer literal constant (with no kind parameter) indicating the *n*th character position to the left of the current character.

If *n* is greater than or equal to the current position, the next character accessed is the first character of the record.

TR Editing

The TR edit descriptor specifies a character position to the *right* of the current position in an I/O record. It takes the following form:

TRn

The *n* is a positive integer literal constant (with no kind parameter) indicating the *n*th character position to the right of the current character.

X Editing

The X edit descriptor specifies a character position to the right of the current position in an I/O record. It takes the following form:

nX

The *n* is a positive integer literal constant (with no kind parameter) indicating the *n*th character position to the right of the current character.

On output, the X edit descriptor does not output any characters when it appears at the end of a format specification; for example:

```
     WRITE (6,99) K
99   FORMAT ('^K=',I6,5X)
```

Note that the symbol ^ represents a nonprinting blank character. This example writes a record of only 9 characters. To cause *n* trailing blanks to be output at the end of a record, specify a format of `n('^')`.

Sign Editing

The SP, SS and S edit descriptors control the output of the optional plus (+) sign within numeric output fields. These descriptors have no effect during execution of input statements.

These specifiers correspond to the SIGN= specifier values PLUS, SUPPRESS, and PROCESSOR_DEFINED, respectively.

Within a format specification, a sign editing descriptor affects all subsequent I, F, E, EN, ES, EX, D, and G descriptors until another sign editing descriptor occurs.

Examples

Consider the following:

```
      INTEGER i
      REAL r

!     The following statements write:
!     251 +251 251 +251 251
      i = 251
      WRITE (*, 100) i, i, i, i, i
100   FORMAT (I5, SP, I5, SS, I5, SP, I5, S, I5)

!     The following statements write:
!     0.673E+4 +.673E+40.673E+4 +.673E+40.673E+4
      r = 67.3E2
      WRITE (*, 200) r, r, r, r, r
200   FORMAT (E8.3E1, 1X, SP, E8.3E1, SS, E8.3E1, 1X, SP, &
     &            E8.3E1, S, E8.3E1)
```

See Also

Forms for Control Edit Descriptors

SP Editing

The SP edit descriptor causes the processor to produce a plus sign in any subsequent position where it would be otherwise optional. It takes the following form:

SP

SS Editing

The SS edit descriptor causes the processor to *suppress* a plus sign in any subsequent position where it would be otherwise optional. It takes the following form:

SS

S Editing

The S edit descriptor restores the plus sign as optional for all subsequent positive numeric fields. It takes the following form:

S

The S edit descriptor restores to the processor the discretion of producing plus characters on an optional basis.

Blank Editing

The BN and BZ descriptors control the interpretation of embedded and trailing blanks within numeric input fields. These descriptors have no effect during execution of output statements.

Within a format specification, a blank editing descriptor affects all subsequent I, B, O, Z, F, E, EN, ES, D, and G descriptors until another blank editing descriptor occurs.

The blank editing descriptors override the effect of the BLANK specifier during execution of a particular input data transfer statement. (For more information, see the BLANK specifier in OPEN statements.)

See Also

Forms for Control Edit Descriptors

BN Editing

The BN edit descriptor causes the processor to *ignore* all embedded and trailing blanks in numeric input fields. It takes the following form:

BN

The input field is treated as if all blanks have been removed and the remainder of the field is right-justified. An all-blank field is treated as zero.

Examples

If an input field formatted as a six-digit integer (I6) contains '2 3 4', it is interpreted as ' 234'.

Consider the following code:

```
      READ (*, 100) n
100   FORMAT (BN, I6)
```

If you enter any one of the following three records and terminate by pressing Enter, the READ statement interprets that record as the value 123:

```
   123
123
123   456
```

Because the repeatable edit descriptor associated with the I/O list item n is I6, only the first six characters of each record are read (three blanks followed by 123 for the first record, and 123 followed by three blanks for the last two records). Because blanks are ignored, all three records are interpreted as 123.

The following example shows the effect of BN editing with an input record that has fewer characters than the number of characters specified by the edit descriptors and *iolist*. Suppose you enter 123 and press Enter in response to the following READ statement:

```
READ (*, '(I6)') n
```

The I/O system is looking for six characters to interpret as an integer number. You have entered only three, so the first thing the I/O system does is to pad the record 123 on the right with three blanks. With BN editing in effect, the nonblank characters (123) are right-aligned, so the record is equal to 123.

BZ Editing

The BZ edit descriptor causes the processor to *interpret* all embedded and trailing blanks in numeric input fields as zeros. It takes the following form:

BZ

Examples

The input field ' 23 4 ' is interpreted as ' 23040'. If ' 23 4' is entered, the formatter adds one blank to pad the input to the six-digit integer format (I6), but this extra space is ignored, and the input is interpreted as ' 2304 '. The blanks following the E or D in real-number input are ignored, regardless of the form of blank interpretation in effect.

Suppose you enter 123 and press Enter in response to the following READ statement:

```
READ (*, '(I6)') n
```

The I/O system is looking for six characters to interpret as an integer number. You have entered only three, so the first thing the I/O system does is to pad the record 123 on the right with three blanks. If BZ editing is in effect, those three blanks are interpreted as zeros, and the record is equal to 123000.

Round Editing

The RU, RD, RZ, RN, RC, and RP edit descriptors temporarily change the I/O rounding mode for a connection.

These forms of rounding correspond to the ROUND= specifier values UP, DOWN, ZERO, NEAREST, COMPATIBLE, and PROCESSOR DEFINED, respectively. Rounding conforms to the ISO/IEC/IEEE 60559:2011 standard.

The I/O rounding mode affects the conversion of real and complex values in formatted I/O. It affects only D, E, EN, ES, EX, F, and G editing.

Each descriptor continues to be in effect until a different round editing descriptor is encountered or until the end of the current I/O statement.

See Also

Forms for Control Edit Descriptors

RU Editing

The RU edit descriptor causes rounding to the smallest value that is greater than or equal to the original value. It takes the following form:

RU

RD Editing

The RD edit descriptor causes rounding to the largest representable value that is less than or equal to the original value. It takes the following form:

RD

RZ Editing

The RZ edit descriptor causes rounding to the value closest to the original value, but not greater in magnitude. It takes the following form:

RZ

RN Editing

The RN edit descriptor selects NEAREST rounding as specified by the ISO/IEC/IEEE 60559:2011 standard. It takes the following form:

RN

RC Editing

The RC edit descriptor causes rounding to the closer of the two nearest representable values. If the value is halfway between the two values, the one chosen is the one farther from zero. It takes the following form:

RC

RP Editing

The RP edit descriptor causes rounding to be determined by the default settings in the processor, which may correspond to one of the other modes. It takes the following form:

RP

Decimal Editing

The DC and DP edit descriptors temporarily change the decimal edit mode for a connection.

These specifiers correspond to the DECIMAL= specifier values COMMA and POINT, respectively.

The decimal editing mode controls the representation of the decimal symbol during conversion of real and complex values in formatted I/O. It affects only D, E, EN, ES, F, and G editing.

Each descriptor continues to be in effect until a different decimal editing descriptor is encountered or until the end of the current I/O statement.

See Also

Forms for Control Edit Descriptors

DC Editing

The DC edit descriptor changes the decimal editing mode for a connection to a decimal comma. It takes the following form:

DC

Note that during list-directed I/O, a semicolon is used as a value separator in place of a comma.

DP Editing

The DP edit descriptor causes rounding to be determined by the default settings in the processor, which may correspond to one of the other modes. It takes the following form:

DP

Scale-Factor Editing (P)

The P edit descriptor specifies a scale factor, which moves the location of the decimal point in real values and the two real parts of complex values. It takes the following form:

*k*P

The *k* is a signed (sign is optional if positive), integer literal constant specifying the number of positions, to the left or right, that the decimal point is to move (the scale factor). The range of *k* is -128 to 127.

At the beginning of a formatted I/O statement, the value of the scale factor is zero. If a scale editing descriptor is specified, the scale factor is set to the new value, which affects all subsequent real edit descriptors until another scale editing descriptor occurs.

To reinstate a scale factor of zero, you must explicitly specify 0P.

Format reversion does not affect the scale factor. (For more information on format reversion, see Interaction Between Format Specifications and I/O Lists.)

Rules for Input Processing

On input, a positive scale factor moves the decimal point to the left, and a negative scale factor moves the decimal point to the right. (On output, the effect is the reverse.)

On input, when an input field using an F, E, D, EN, ES, EX, or G real edit descriptor contains an explicit exponent, the scale factor has no effect. Otherwise, the internal value of the corresponding I/O list item is equal to the external field data multiplied by 10^{-k}. For example, a 2P scale factor multiplies an input value by .01, moving the decimal point two places to the left. A -2P scale factor multiplies an input value by 100, moving the decimal point two places to the right.

The scale factor applies to decimal numbers without an exponent. For hexadecimal-significand numbers, the exponent is mandatory so the scale factor has no effect.

The following shows input using the P edit descriptor (the symbol ^ represents a nonprinting blank character):

```
Format    Input         Value
3PE10.5   ^^^37.614^         .037614
3PE10.5   ^^37.614E2     3761.4
-3PE10.5  ^^^^37.614    37614.0
```

The scale factor must precede the first real edit descriptor associated with it, but it need not immediately precede the descriptor. For example, the following all have the same effect:

```
  (3P, I6, F6.3, E8.1)
  (I6, 3P, F6.3, E8.1)
  (I6, 3PF6.3, E8.1)
```

Note that if the scale factor immediately precedes the associated real edit descriptor, the comma separator is optional.

Rules for Output Processing

On output, a positive scale factor moves the decimal point to the right, and a negative scale factor moves the decimal point to the left. (On input, the effect is the reverse.)

On output, the effect of the scale factor depends on which kind of real editing is associated with it, as follows:

- For F editing, the external value equals the internal value of the I/O list item multiplied by 10^{k}. This changes the magnitude of the data.
- For E and D editing, the external decimal field of the I/O list item is multiplied by 10^{k}, and *k* is subtracted from the exponent. This changes the form of the data.

  A positive scale factor decreases the exponent; a negative scale factor increases the exponent.

  For a positive scale factor, *k* must be less than *d* + 2 or an output conversion error occurs.
- For G editing, the scale factor has no effect if the magnitude of the data to be output is within the effective range of the descriptor (the G descriptor supplies its own scaling).

  If the magnitude of the data field is outside G descriptor range, E editing is used, and the scale factor has the same effect as E output editing.
- For EN, ES, and EX editing, the scale factor has no effect.

The following shows output using the P edit descriptor (the symbol ^ represents a nonprinting blank character):

```
Format     Value         Output
1PE12.3    -270.139      ^^-2.701E+02
1P,E12.2   -270.139      ^^^-2.70E+02
-1PE12.2   -270.139      ^^^-0.03E+04
```

Examples

The following shows a FORMAT statement containing a scale factor:

```
     DIMENSION A(6)
     DO 10 I=1,6
10   A(I) = 25.
     WRITE (6, 100) A
100  FORMAT(' ', F8.2, 2PF8.2, F8.2)
```

The preceding statements produce the following results:

```
   25.00  2500.00  2500.00
 2500.00  2500.00  2500.00
```

The following code uses scale-factor editing when reading:

```
      READ (*, 100) a, b, c, d
100   FORMAT (F10.6, 1P, F10.6, F10.6, -2P, F10.6)

      WRITE (*, 200) a, b, c, d
200   FORMAT (4F11.3)
```

If the following data is entered:

```
12340000  12340000  12340000  12340000
   12.34     12.34     12.34     12.34
 12.34e0   12.34e0   12.34e0   12.34e0
 12.34e3   12.34e3   12.34e3   12.34e3
```

The program's output is:

```
   12.340      1.234      1.234   1234.000
   12.340      1.234      1.234   1234.000
   12.340     12.340     12.340     12.340
12340.000  12340.000  12340.000  12340.000
```

The next code shows scale-factor editing when writing:

```
      a = 12.34

      WRITE (*, 100) a, a, a, a, a, a
100   FORMAT (1X, F9.4, E11.4E2, 1P, F9.4, E11.4E2, &
     &        -2P, F9.4, E11.4E2)
```

This program's output is:

```
12.3400 0.1234E+02 123.4000 1.2340E+01   0.1234 0.0012E+04
```

See Also

Forms for Control Edit Descriptors

Slash Editing (/)

The slash edit descriptor terminates data transfer for the current record and starts data transfer for a new record. It takes the following form:

[r]/

The *r* is a repeat specification. It must be a positive default integer literal constant; no kind parameter can be specified.

The range of *r* is 1 through 2147483647 (2**31-1) on Intel® 64 architecture; 1 through 32767 (2**15-1) on IA-32 architecture. If *r* is omitted, it is assumed to be 1.

Multiple slashes cause the system to skip input records or to output blank records, as follows:

- When *n* consecutive slashes appear between two edit descriptors, *n* - 1 records are skipped on input, or *n* - 1 blank records are output. The first slash terminates the current record. The second slash terminates the first skipped or blank record, and so on.
- When *n* consecutive slashes appear at the beginning or end of a format specification, *n* records are skipped or *n* blank records are output, because the opening and closing parentheses of the format specification are themselves a record initiator and terminator, respectively. For example, suppose the following statements are specified:

```
    WRITE (6,99)
99  FORMAT ('1',T51,'HEADING LINE'//T51,'SUBHEADING LINE'//)
```

The following lines are written:

```
                  Column 50, top of page         |         HEADING LINE
(blank line)         SUBHEADING LINE
(blank line)
(blank line)
```

Note that the first character of the record printed was reserved as a control character (see Printing of Formatted Records).

Examples

```
!     The following statements write spreadsheet column and row labels:
      WRITE (*, 100)
100   FORMAT ('   A     B     C     D     E'                              &
     &        /,' 1',/,' 2',/,' 3',/,' 4',/,' 5')
```

The above example generates the following output:

```
  A     B     C     D     E
1
2
3
4
5
```

See Also

Forms for Control Edit Descriptors

Colon Editing (:)

The colon edit descriptor terminates format control if there are no more items in the I/O list.

Examples

Suppose the following statements are specified:

```
    PRINT 1,3
    PRINT 2,13
1   FORMAT (' I=',I2,' J=',I2)
2   FORMAT (' K=',I2,:,' L=',I2)
```

The above code causes the following lines to be written (the symbol ^ represents a nonprinting blank character):

```
I=^3^J=
K=13
```

The following shows another example:

```
!     The following example writes a= 3.20 b= .99
      REAL a, b, c, d
      DATA a /3.2/, b /.9871515/
```

```
      WRITE (*, 100) a, b
100   FORMAT (' a=', F5.2, :, ' b=', F5.2, :, &
     &        ' c=', F5.2, :, ' d=', F5.2)
      END
```

See Also

Forms for Control Edit Descriptors

Dollar-Sign ($) and Backslash (\ ) Editing

The dollar sign and backslash edit descriptors modify the output of carriage control specified by the first character of the record. They only affect carriage control for formatted files, and have no effect on input.

If the first character of the record is a blank or a plus sign (+), the dollar sign and backslash descriptors suppress carriage return (after printing the record).

For terminal device I/O, when this trailing carriage return is suppressed, a response follows output on the same line. For example, suppose the following statements are specified:

```
      TYPE 100
100   FORMAT (' ENTER RADIUS VALUE ',$)
      ACCEPT 200, RADIUS
200   FORMAT (F6.2)
```

The following prompt is displayed:

```
 ENTER RADIUS VALUE
```

Any response (for example, "12.") is then displayed on the same line:

```
 ENTER RADIUS VALUE    12.
```

If the first character of the record is 0, 1, or ASCII NUL, the dollar sign and backslash descriptors have no effect.

Consider the following:

```
     CHARACTER(20) MYNAME
     WRITE (*,9000)
9000 FORMAT ('Please type your name:',\)
     READ  (*,9001) MYNAME
9001 FORMAT (A20)
     WRITE (*,9002) ' ',MYNAME
9002 FORMAT (1X,A20)
```

This example advances two lines, prompts for input, awaits input on the same line as the prompt, and prints the input.

The following shows the same example using Fortran standard constructs:

```
     CHARACTER(20) MYNAME
     WRITE (*,9000, ADVANCE='NO')
9000 FORMAT ('Please type your name:')
     READ  (*,9001) MYNAME
9001 FORMAT (A20)
     WRITE (*,9002) ' ',MYNAME
9002 FORMAT (1X,A20)
```

See Also

Forms for Control Edit Descriptors

Character Count Editing (Q)

The character count edit descriptor returns the remaining number of characters in the current input record.

The corresponding I/O list item must be of type integer or logical. For example, suppose the following statements are specified:

```
      READ (4,1000) XRAY, KK, NCHRS, (ICHR(I), I=1,NCHRS)
1000  FORMAT (E15.7,I4,Q,(80A1))
```

Two fields are read into variables XRAY and KK. The number of characters remaining in the record is stored in NCHRS, and exactly that many characters are read into the array ICHR. (This instruction can fail if the record is longer than 80 characters.)

If you place the character count descriptor first in a format specification, you can determine the length of an input record.

On output, the character count edit descriptor causes the corresponding I/O list item to be skipped.

Examples

Consider the following:

```
      CHARACTER ICHAR(80)
      READ (4, 1000) XRAY, K, NCHAR, (ICHAR(I), I= 1, NCHAR)
1000  FORMAT (E15.7, I4, Q, 80A1)
```

The preceding input statement reads the variables XRAY and K. The number of characters remaining in the record is NCHAR, specified by the Q edit descriptor. The array ICHAR is then filled by reading exactly the number of characters left in the record. (Note that this instruction will fail if NCHAR is greater than 80, the length of the array ICHAR.) By placing Q in the format specification, you can determine the actual length of an input record.

Note that the length returned by Q is the number of characters left in the record, not the number of reals or integers or other data types. The length returned by Q can be used immediately after it is read and can be used later in the same format statement or in a variable format expression. (See Variable Format Expressions.)

Assume the file Q.DAT contains:

```
1234.567Hello, Q Edit
```

The following program reads in the number REAL1, determines the characters left in the record, and reads those into STR:

```
      CHARACTER STR(80)
      INTEGER LENGTH
      REAL REAL1
      OPEN (UNIT = 10, FILE = 'Q.DAT')
100   FORMAT (F8.3, Q, 80A1)
      READ (10, 100) REAL1, LENGTH, (STR(I), I=1, LENGTH)
      WRITE(*,'(F8.3,2X,I2,2X,<LENGTH>A1)') REAL1, LENGTH, (STR(I), &
     & I= 1, LENGTH)
      END
```

The output on the screen is:

```
1234.567  13  Hello, Q Edit
```

A READ statement that contains only a Q edit descriptor advances the file to the next record. For example, consider that Q.DAT contains the following data:

```
abcdefg
abcd
```

Consider it is then READ with the following statements:

```
      OPEN (10, FILE = "Q.DAT")
      READ(10, 100) LENGTH
100   FORMAT(Q)
      WRITE(*,'(I2)') LENGTH
      READ(10, 100) LENGTH
      WRITE(*,'(I2)') LENGTH
      END
```

The output to the screen would be:

```
7
4
```

Forms for Control Edit Descriptors

Character String Edit Descriptors

Character string edit descriptors control the output of character strings. The character string edit descriptors are the character constant and H edit descriptor.

Although no string edit descriptor can be preceded by a repeat specification, a parenthesized group of string edit descriptors can be preceded by a repeat specification or a * indicating an unlimited repeat count.

See Also

Nested and Group Repeat Specifications

Character Constant Editing

The character constant edit descriptor causes a character string to be output to an external record. It takes one of the following forms:

'*string*'

"*string*"

The *string* is a character literal constant; no kind parameter can be specified. Its length is the number of characters between the delimiters; two consecutive delimiters are counted as one character.

To include an apostrophe in a character constant that is enclosed by apostrophes, place two consecutive apostrophes ('') in the format specification; for example:

```
50   FORMAT ('TODAY''S^DATE^IS:^',I2,'/',I2,'/',I2)
```

Note that the symbol ^ represents a nonprinting blank character.

Similarly, to include a quotation mark in a character constant that is enclosed by quotation marks, place two consecutive quotation marks ("") in the format specification.

On input, the character constant edit descriptor transfers length of string characters to the edit descriptor.

Examples

Consider the following '(3I5)' format in the WRITE statement:

```
WRITE (10, '(3I5)') I1, I2, I3
```

This is equivalent to:

```
      WRITE (10, 100) I1, I2, I3
100   FORMAT( 3I5)
```

The following shows another example:

```
!     These WRITE statements both output ABC'DEF
!     (The leading blank is a carriage-control character).
      WRITE (*, 970)
970   FORMAT (' ABC''DEF')
      WRITE (*, '('' ABC''''DEF'')')
!     The following WRITE also outputs ABC'DEF. No carriage-
!     control character is necessary for list-directed I/O.
      WRITE (*,*) 'ABC''DEF'
```

Alternatively, if the delimiter is quotation marks, the apostrophe in the character constant `ABC'DEF` requires no special treatment:

```
WRITE (*,*) "ABC'DEF"
```

Character constants
Format Specifications

H Editing

The H edit descriptor transfers data between the external record and the H edit descriptor itself. The H edit descriptor is a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

An H edit descriptor has the form of a Hollerith constant, as follows:

*n*H*string*

n	Is an unsigned, positive default integer literal constant (with no kind parameter) indicating the number of characters in *string* (including blanks and tabs). The range of *n* is 1 through 2147483647 (2**31-1) on Intel® 64 architecture; 1 through 32767 (2**15-1) on IA-32 architecture. Actual useful ranges may be constrained by record sizes (RECL) and the file system.
string	Is a string of printable ASCII characters.

On input, the H edit descriptor transfers *n* characters from the external field to the edit descriptor. The first character appears immediately after the letter H. Any characters in the edit descriptor before input are replaced by the input characters. If the edit descriptor appears in a FORMAT statement, the replaced characters are preserved for future uses of that FORMAT statement; otherwise, the replacement is discarded.

On output, the H edit descriptor causes *n* characters following the letter H to be output to an external record.

Examples

```
!     These WRITE statements both print "Don't misspell 'Hollerith'"
!     (The leading blanks are carriage-control characters).
!     Hollerith formatting does not require you to embed additional
!     single quotation marks as shown in the second example.
!
      WRITE (*, 960)
960   FORMAT (27H Don't misspell 'Hollerith')
      WRITE (*, 961)
961   FORMAT (' Don''t misspell ''Hollerith''')
```

Deleted and Obsolescent Language Features

Format Specifications

Nested and Group Repeat Specifications

Format specifications can include nested format specifications enclosed in parentheses; for example:

```
15   FORMAT (E7.2,I8,I2,(A5,I6))
35   FORMAT (A6,(L8(3I2)),A)
```

A group repeat specification can precede a nested group of edit descriptors; it can be an unsigned integer literal constant, a variable format expression, or * to indicate an unlimited repeat count. For example, the following statements are equivalent, and the second statement shows a group repeat specification:

```
50   FORMAT (I8,I8,F8.3,E15.7,F8.3,E15.7,F8.3,E15.7,I5,I5)
50   FORMAT (2I8,3(F8.3,E15.7),2I5)
```

If a nested group does not show a repeat count, a default count of 1 is assumed.

Normally, the string edit descriptors and control edit descriptors cannot be repeated (except for slash), but any of these descriptors can be enclosed in parentheses and preceded by a group repeat specification. For example, the following statements are valid:

```
76   FORMAT ('MONTHLY',3('TOTAL'))
100  FORMAT (I8,4(T7),A4)
```

Each of the following can be used to read data at the end of an input record into N elements of array A:

```
    read (10,'(<N>F8.2)') A(1:N)  ! Variable format expression
    read(10,'(*(F8.2))') A(1:N)   ! Unlimited repeat count
```

Interaction Between Format Specifications and I/O Lists for details on group repeat specifications and format reversion

Variable Format Expressions

A variable format expression is a numeric expression enclosed in angle brackets (< >) that can be used in a FORMAT statement or in a character format specification.

The numeric expression can be any valid Fortran expression, including function calls and references to dummy arguments.

If the expression is not of type integer, it is converted to integer type before being used.

If the value of a variable format expression does not obey the restrictions on magnitude applying to its use in the format, an error occurs.

Variable format expressions cannot be used with the H edit descriptor, and they are not allowed in character format specifications that are not character constant expressions.

Variable format expressions are evaluated each time they are encountered in the scan of the format. If the value of the variable used in the expression changes during the execution of the I/O statement, the new value is used the next time the format item containing the expression is processed.

Examples

Consider the following statement:

```
  FORMAT (I<J+1>)
```

When the format is scanned, the preceding statement performs an I (integer) data transfer with a field width of J+1. The expression is reevaluated each time it is encountered in the normal format scan.

Consider the following statements:

```
      DIMENSION A(5)
      DATA A/1.,2.,3.,4.,5./

      DO 10 I=1,10
      WRITE (6,100) I
100   FORMAT (I<MAX(I,5)>)
10    CONTINUE

      DO 20 I=1,5
      WRITE (6,101) (A(I), J=1,I)
101   FORMAT (<I>F10.<I-1>)
20    CONTINUE
      END
```

On execution, these statements produce the following output:

```
    1
    2
    3
    4
    5
     6
      7
       8
        9
        10
        1.
       2.0        2.0
      3.00       3.00     3.00
     4.000      4.000    4.000     4.000
    5.0000    5.0000    5.0000    5.0000    5.0000
```

The following shows another example:

```
       WRITE(6,20) INT1
20     FORMAT(I<MAX(20,5)>)

       WRITE(6,FMT=30) REAL2(10), REAL3
30     FORMAT(<J+K>X, <2*M>F8.3)
```

The value of the expression is reevaluated each time an input/output item is processed during the execution of the READ, WRITE, or PRINT statement. For example:

```
       INTEGER width, value
       width=2
       READ (*,10) width, value
10     FORMAT(I1, I <width>)
       PRINT *, value
       END
```

When given input 3123, the program will print 123 and not 12.

See Also

Interaction Between Format Specifications and I/O Lists for details on the synchronization of I/O lists with formats

Printing of Formatted Records

On output, if a file was opened with CARRIAGECONTROL='FORTRAN' in effect, the first character of a record transmitted to a line printer or terminal is typically a character that is not printed, but used to control vertical spacing.

Printing control characters are a deleted feature in the Fortran Standard. Intel® Fortran fully supports features deleted in the Fortran Standard.

The following table lists the valid control characters for printing:

Control Characters for Printing

Character	Meaning	Effect
+	Overprinting	Outputs the record (at the current position in the current line) and a carriage return.
-	One line feed	Outputs the record (at the beginning of the following line) and a carriage return.
0	Two line feeds	Outputs the record (after skipping a line) and a carriage return.
1	Next page	Outputs the record (at the beginning of a new page) and a carriage return.
$	Prompting	Outputs the record (at the beginning of the following line), but no carriage return.
ASCII NUL[1]	Overprinting with no advance	Outputs the record (at the current position in the current line), but no carriage return.

[1] Specify as CHAR(0).

Any other character is interpreted as a blank and is deleted from the print line. If you do not specify a control character for printing, the first character of the record is not printed.

Interaction Between Format Specifications and I/O Lists

Format control begins with the execution of a formatted I/O statement. Each action of format control depends on information provided jointly by the next item in the I/O list (if one exists) and the next edit descriptor in the format specification.

Both the I/O list and the format specification are interpreted from left to right, unless repeat specifications or implied-DO lists appear.

If an I/O list specifies at least one list item, at least one data edit descriptor (I, B, O, Z, F, E, EN, ES, EX, D, G, L, or A) or the Q edit descriptor must appear in the format specification; otherwise, an error occurs.

Each data edit descriptor (or Q edit descriptor) corresponds to one item in the I/O list, except that an I/O list item of type complex requires the interpretation of two F, E, EN, ES, EX, D, or G edit descriptors. No I/O list item corresponds to a control edit descriptor (X, P, T, TL, TR, SP, SS, S, BN, BZ, $, or :), or a character string edit descriptor (H and character constants). For character string edit descriptors, data transfer occurs directly between the external record and the format specification.

When format control encounters a data edit descriptor in a format specification, it determines whether there is a corresponding I/O list item specified. If there is such an item, it is transferred under control of the edit descriptor, and then format control proceeds. If there is no corresponding I/O list item, format control terminates.

If there are no other I/O list items to be processed, format control also terminates when the following occurs:

- A colon edit descriptor is encountered.
- The end of the format specification is reached.

If additional I/O list items remain, part or all of the format specification is reused in format reversion.

In format reversion, the current record is terminated and a new one is initiated. Format control then reverts to one of the following (in order) and continues from that point:

1. The group repeat specification whose opening parenthesis matches the next-to-last closing parenthesis of the format specification
2. The initial opening parenthesis of the format specification

Format reversion has no effect on the scale factor (P), the sign control edit descriptors (S, SP, or SS), or the blank interpretation edit descriptors (BN or BZ).

Examples

The data in file FOR002.DAT is to be processed 2 records at a time. Each record starts with a number to be put into an element of a vector B, followed by 5 numbers to be put in a row in matrix A.

FOR002.DAT contains the following data:

```
001 0101 0102 0103 0104 0105
002 0201 0202 0203 0204 0205
003 0301 0302 0303 0304 0305
004 0401 0402 0403 0404 0405
005 0501 0502 0503 0504 0505
006 0601 0602 0603 0604 0605
007 0701 0702 0703 0704 0705
008 0801 0802 0803 0804 0805
009 0901 0902 0903 0904 0905
010 1001 1002 1003 1004 1005
```

The following example shows how several different format specifications interact with I/O lists to process data in file FOR002.DAT:

```
      INTEGER I, J, A(2,5), B(2)
      OPEN (unit=2, access='sequential', file='FOR002.DAT')

      READ (2,100) (B(I), (A(I,J), J=1,5),I=1,2) 1

100   FORMAT (2 (I3, X, 5(I4,X), /) ) 2

      WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2) 3

999   FORMAT (' B is ', 2(I3, X), ';  A is', /
     1       (' ', 5 (I4, X)) )

      READ (2,200) (B(I), (A(I,J), J=1,5),I=1,2) 4

200   FORMAT (2 (I3, X, 5(I4,X), :/) )
      WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2) 5
```

```
      READ (2,300) (B(I), (A(I,J), J=1,5),I=1,2) 6
300   FORMAT ( (I3, X, 5(I4,X)) )
      WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2) 7
      READ (2,400) (B(I), (A(I,J), J=1,5),I=1,2) 8
400   FORMAT ( I3, X, 5(I4,X) )
      WRITE (6,999) B, ((A(I,J),J=1,5),I=1,2) 9
      END
```

1 This statement reads B(1); then A(1,1) through A(1,5); then B(2) and A(2,1) through A(2,5).

The first record read (starting with 001) starts the processing of the I/O list.

2 There are two records, each in the format I3, X, 5(I4, X). The slash (/) forces the reading of the second record after A(1,5) is processed. It also forces the reading of the third record after A(2,5) is processed; no data is taken from that record.

3 This statement produces the following output:

```
B is   1   2 ;  A is 101  102  103  104  105 201  202  203  204  205
```

4 This statement reads the record starting with 004. The slash (/) forces the reading of the next record after A(1,5) is processed. The colon (:) stops the reading after A(2,5) is processed, but before the slash (/) forces another read.

5 This statement produces the following output:

```
B is   4   5 ;  A is 401  402  403  404  405 501  502  503  504  505
```

6 This statement reads the record starting with 006. After A(1,5) is processed, format reversion causes the next record to be read and starts format processing at the left parenthesis before the I3.

7 This statement produces the following output:

```
B is   6   7 ;  A is 601  602  603  604  605 701  702  703  704  705
```

8 This statement reads the record starting with 008. After A(1,5) is processed, format reversion causes the next record to be read and starts format processing at the left parenthesis before the I4.

9 This statement produces the following output:

```
B is   8  90 ;  A is 801  802  803  804  805 9010 9020 9030 9040 100
```

The record 009 0901 0902 0903 0904 0905 is processed with I4 as "009 " for B(2), which is 90. X skips the next "0". Then "901 " is processed for A(2,1), which is 9010, "902 " for A(2,2), "903 " for A(2,3), and "904 " for A(2,4). The repeat specification of 5 is now exhausted and the format ends. Format reversion causes another record to be read and starts format processing at the left parenthesis before the I4, so "010 " is read for A(2,5), which is 100.

File Operation I/O Statements

The following are file connection, inquiry, and positioning I/O statements:

- BACKSPACE

  Positions a sequential file at the beginning of the preceding record, making it available for subsequent I/O processing.
- CLOSE

  Terminates the connection between a logical unit and a file or device.
- DELETE

  Deletes a record from a relative file.
- ENDFILE

  Writes an end-of-file record to a sequential file and positions the file after this record (the terminal point). For direct access files, truncates the file after the current record.
- FLUSH

  Causes data written to a file to become available to other processes or causes data written to a file outside of Fortran to be accessible to a READ statement.
- INQUIRE

  Requests information on the status of specified properties of a file or logical unit. For more information on specifiers you can use in INQUIRE statements, see INQUIRE Statement Specifiers.
- OPEN

  Connects a Fortran logical unit to a file or device; declares attributes for read and write operations. For more information on specifiers you can use in OPEN statements, see OPEN Statement Specifiers.
- REWIND

  Positions a sequential or direct access file at the beginning of the file (the initial point).
- WAIT

  Performs a wait operation for a specified pending asynchronous data transfer operation.

The following table summarizes I/O statement specifiers:

I/O Specifiers			
Specifier	**Values**	**Description**	**Used with:**
ACCESS=*access*	'SEQUENTIAL', 'DIRECT', 'STREAM', or 'APPEND'	Specifies the method of file access.	INQUIRE, OPEN
ACTION=*permission*	'READ', 'WRITE' or 'READWRITE' (default is 'READWRITE')	Specifies file I/O mode.	INQUIRE, OPEN
ADVANCE=*c-expr*	'NO' or 'YES' (default is 'YES')	Specifies formatted sequential data input as advancing, or non-advancing.	READ

I/O Specifiers			
Specifier	**Values**	**Description**	**Used with:**
ASSOCIATEVARIABLE=*var*	Integer variable	Specifies a variable to be updated to reflect the record number of the next sequential record in the file.	OPEN
ASYNCHRONOUS=*asynch*	'YES' or 'NO' (default is 'NO')	Specifies whether or not the I/O is done asynchronously	INQUIRE, OPEN
BINARY=*bin*	'NO' or 'YES'	Returns whether file format is binary.	INQUIRE
BLANK=*blank_control*	'NULL' or 'ZERO' (default is 'NULL')	Specifies whether blanks are ignored in numeric fields or interpreted as zeros.	INQUIRE, OPEN
BLOCKSIZE=*blocksize*	Positive integer variable or expression	Specifies or returns the internal buffer size used in I/O.	INQUIRE, OPEN
BUFFERCOUNT=*bc*	Numeric expression	Specifies the number of buffers to be associated with the unit for multibuffered I/O.	OPEN
BUFFERED=*bf*	'YES' or 'NO' (default is 'NO')	Specifies run-time library behavior following WRITE operations.	INQUIRE, OPEN
CARRIAGECONTROL=*control*	'FORTRAN', 'LIST', or 'NONE'	Specifies carriage control processing.	INQUIRE, OPEN
CONVERT=*form*	'LITTLE_ENDIAN', 'BIG_ENDIAN', 'CRAY', 'FDX', 'FGX', 'IBM', 'VAXD', 'VAXG', or 'NATIVE' (default is 'NATIVE')	Specifies a numeric format for unformatted data.	INQUIRE, OPEN
DEFAULTFILE=*var*	Character expression	Specifies a default file pathname string.	INQUIRE, OPEN
DELIM=*delimiter*	'APOSTROPHE', 'QUOTE' or 'NONE' (default is 'NONE')	Specifies the delimiting character for list-directed or namelist data.	INQUIRE, OPEN
DIRECT=*dir*	'NO' or 'YES'	Returns whether file is connected for direct access.	INQUIRE
DISPOSE=*dis* (or DISP=*dis*)	'KEEP', 'SAVE', 'DELETE', 'PRINT', 'PRINT/DELETE', 'SUBMIT', or 'SUBMIT/DELETE'	Specifies the status of a file after the unit is closed.	OPEN, CLOSE

I/O Specifiers			
Specifier	**Values**	**Description**	**Used with:**
	(default is 'DELETE' for scratch files; 'KEEP' for all other files)		
formatlist	Character variable or expression	Lists edit descriptors. Used in FORMAT statements and format specifiers (the FMT=*formatspec* option) to describe the format of data.	FORMAT, PRINT, READ, WRITE
END=*endlabel*	Integer between 1 and 99999	When an end of file is encountered, transfers control to the statement whose label is specified.	READ
EOR=*eorlabel*	Integer between 1 and 99999	When an end of record is encountered, transfers to the statement whose label is specified.	READ
ERR=*errlabel*	Integer between 1 and 99999	Specifies the label of an executable statement where execution is transferred after an I/O error.	All except PRINT
EXIST=*ex*	.TRUE. or .FALSE.	Returns whether a file exists and can be opened.	INQUIRE
FILE=*file*(or NAME=*name*)	Character variable or expression. Length and format of the name are determined by the operating system	Specifies the name of a file	INQUIRE, OPEN
[FMT=]*formatspec*	Character variable or expression	Specifies an *editlist* to use to format data.	PRINT, READ, WRITE
FORM=*form*	'FORMATTED', 'UNFORMATTED', or 'BINARY'	Specifies a file's format.	INQUIRE, OPEN
FORMATTED=*fmt*	'NO' or 'YES'	Returns whether a file is connected for formatted data transfer.	INQUIRE
IOFOCUS=*iof*	.TRUE. or .FALSE. (default is .TRUE. unless unit '*' is specified)	Specifies whether a unit is the active window in a QuickWin application.	INQUIRE, OPEN
iolist	List of variables of any type, character expression, or NAMELIST	Specifies items to be input or output.	PRINT, READ, WRITE

I/O Specifiers			
Specifier	**Values**	**Description**	**Used with:**
IOSTAT=*iostat*	Integer variable	Specifies a variable whose value indicates whether an I/O error has occurred.	All except PRINT
MAXREC=*var*	Numeric expression	Specifies the maximum number of records that can be transferred to or from a direct access file.	OPEN
MODE=*permission*	'READ', 'WRITE' or 'READWRITE' (default is 'READWRITE')	Same as ACTION.	INQUIRE, OPEN
NAMED=*var*	.TRUE. or .FALSE.	Returns whether a file is named.	INQUIRE
NEWUNIT=*u-var*	Scalar integer variable	Is assigned an unused unit number that is automatically chosen. It is always a negative integer.	OPEN
NEXTREC=*nr*	Integer variable	Returns where the next record can be read or written in a file.	INQUIRE
[NML=]*nmlspec*	Namelist name	Specifies a *namelist* group to be input or output.	PRINT, READ, WRITE
NUMBER=*num*	Integer variable	Returns the number of the unit connected to a file.	INQUIRE
OPENED=*od*	.TRUE. or .FALSE.	Returns whether a file is connected.	INQUIRE
ORGANIZATION=*org*	'SEQUENTIAL' or 'RELATIVE' (default is 'SEQUENTIAL')	Specifies the internal organization of a file.	INQUIRE, OPEN
PAD=*pad_switch*	'YES' or 'NO' (default is 'YES')	Specifies whether an input record is padded with blanks when the input list or format requires more data than the record holds, or whether the input record is required to contain the data indicated.	INQUIRE, OPEN
POS=*pos*	Positive integer	Specifies the file storage unit position in a stream file.	INQUIRE, READ, WRITE

I/O Specifiers			
Specifier	**Values**	**Description**	**Used with:**
POSITION=*file_pos*	'ASIS', 'REWIND' or 'APPEND' (default is 'ASIS')	Specifies position in a file.	INQUIRE, OPEN
READ=*rd*	'NO' or 'YES'	Returns whether a file can be read.	INQUIRE
READONLY		Specifies that only READ statements can refer to this connection.	OPEN
READWRITE=*rdwr*	'NO' or 'YES'	Returns whether a file can be both read and written to.	INQUIRE
REC=*rec*	Positive integer variable or expression	Specifies the first (or only) record of a file to be read from, or written to.	READ, WRITE
RECL=*length*(or RECORDSIZE=*length*)	Positive integer variable or expression	Specifies the record length in direct access files, or the maximum record length in sequential files.	INQUIRE, OPEN
RECORDTYPE=*typ*	'FIXED', 'VARIABLE', 'SEGMENTED', 'STREAM', 'STREAM_LF', or 'STREAM_CR'	Specifies the type of records in a file.	INQUIRE, OPEN
SEQUENTIAL=*seq*	'NO' or 'YES'	Returns whether file is connected for sequential access.	INQUIRE
SHARE=*share*	'COMPAT', 'DENYNONE', 'DENYWR', 'DENYRD', or 'DENYRW' (default is 'DENYNONE')	Controls how other processes can simultaneously access a file on networked systems.	INQUIRE, OPEN
SHARED		Specifies that a file is connected for shared access by more than one program executing simultaneously.	OPEN
SIZE=*size*	Integer variable	Returns the number of characters read in a nonadvancing READ before an end-of-record condition occurred.	READ
STATUS=*status*(or TYPE=*status*)	'OLD', 'NEW', 'UNKNOWN' or 'SCRATCH' (default is 'UNKNOWN')	Specifies the status of a file on opening and/or closing.	CLOSE, OPEN

I/O Specifiers			
Specifier	**Values**	**Description**	**Used with:**
TITLE=*name*	Character expression	Specifies the name of a child window in a QuickWin application.	OPEN
UNFORMATTED=*unf*	'NO' or 'YES'	Returns whether a file is connected for unformatted data transfer.	INQUIRE
[UNIT=]*unitspec*	Integer variable or expression	Specifies the unit to which a file is connected.	All except PRINT
USEROPEN=*fname*	Name of a user-written function	Specifies an external function that controls the opening of a file.	OPEN
WRITE=*rd*	'NO' or 'YES'	Returns whether a file can be written to.	INQUIRE

INQUIRE Statement Specifiers

The INQUIRE statement returns information on the status of specified properties of a file or logical unit. For more information, see INQUIRE.

The following table lists the INQUIRE statement specifiers and contains links to their descriptions:

ACCESS	DELIM	NEXTREC	RECL
ACTION	DIRECT	NUMBER	RECORDTYPE
ASYNCHRONOUS	ENCODING	OPENED	ROUND
BINARY	EXIST	ORGANIZATION	SEQUENTIAL
BLANK	FORM	PAD	SHARE
BLOCKSIZE	FORMATTED	PENDING	SIGN
BUFFERED	IOFOCUS	POS	SIZE
CARRIAGECONTROL	MODE	POSITION	UNFORMATTED
CONVERT	NAME	READ	WRITE
DECIMAL	NAMED	READWRITE

ERR control specifier
ID control specifier
IOMSG control specifier
IOSTAT control specifier

RECL specifier in OPEN statements
FILE specifier in OPEN statements
DEFAULTFILE specifier in OPEN statements

INQUIRE: ACCESS Specifier

The ACCESS specifier asks how a file is connected. It takes the following form:

ACCESS = *acc*

acc Is a scalar default character variable that is assigned one of the following values:

'SEQUENTIAL'	If the file is connected for sequential access
'STREAM'	If the file is connected for stream access
'DIRECT'	If the file is connected for direct access
'UNDEFINED'	If the file is not connected

INQUIRE: ACTION Specifier

The ACTION specifier asks which I/O operations are allowed for a file. It takes the following form:

ACTION = *act*

act Is a scalar default character variable that is assigned one of the following values:

'READ'	If the file is connected for input only
'WRITE'	If the file is connected for output only
'READWRITE'	If the file is connected for both input and output
'UNDEFINED'	If the file is not connected

INQUIRE: ASYNCHRONOUS Specifier

The ASYNCHRONOUS specifier asks whether asynchronous I/O is in effect. It takes the following form:

ASYNCHRONOUS = *asyn*

asyn Is a scalar default character variable that is assigned one of the following values:

'NO'	If the file or unit is connected and asynchronous input/output is not in effect.
'YES'	If the file or unit is connected and asynchronous input/output is in effect.

'UNKNOWN'	If the file or unit is not connected.

INQUIRE: BINARY Specifier (W*S)

The BINARY specifier asks whether a file is connected to a binary file. It takes the following form:

BINARY = *bin*

bin Is a scalar default character variable that is assigned one of the following values:

'YES'	If the file is connected to a binary file
'NO'	If the file is connected to a nonbinary file
'UNKNOWN'	If the file is not connected

INQUIRE: BLANK Specifier

The BLANK specifier asks what type of blank control is in effect for a file. It takes the following form:

BLANK = *blnk*

blnk Is a scalar default character variable that is assigned one of the following values:

'NULL'	If null blank control is in effect for the file
'ZERO'	If zero blank control is in effect for the file
'UNDEFINED'	If the file is not connected, or it is not connected for formatted data transfer

INQUIRE: BLOCKSIZE Specifier

The BLOCKSIZE specifier asks about the physical I/O transfer size. It takes the following form:

BLOCKSIZE = *bks*

bks Is a scalar integer variable.

The *bks* is assigned the current size of the physical I/O transfer. If the unit or file is not connected, the value assigned is zero.

INQUIRE: BUFFERED Specifier

The BUFFERED specifier asks whether run-time buffering is in effect. It takes the following form:

BUFFERED = *bf*

bf Is a scalar default character variable that is assigned one of the following values:

'NO'	If the file or unit is connected and buffering is not in effect.
'YES'	If the file or unit is connected and buffering is in effect.
'UNKNOWN'	If the file or unit is not connected.

INQUIRE: CARRIAGECONTROL Specifier

The CARRIAGECONTROL specifier asks what type of carriage control is in effect for a file. It takes the following form:

CARRIAGECONTROL = *cc*

cc Is a scalar default character variable that is assigned one of the following values:

'FORTRAN'	If the file is connected with Fortran carriage control in effect
'LIST'	If the file is connected with implied carriage control in effect
'NONE'	If the file is connected with no carriage control in effect
'UNKNOWN'	If the file is not connected

INQUIRE: CONVERT Specifier

The CONVERT specifier asks what type of data conversion is in effect for a file. It takes the following form:

CONVERT = *fm*

fm Is a scalar default character variable that is assigned one of the following values:

'LITTLE_ENDIAN'	If the file is connected with little endian integer and IEEE* floating-point data conversion in effect
'BIG_ENDIAN'	If the file is connected with big endian integer and IEEE floating-point data conversion in effect
'CRAY'	If the file is connected with big endian integer and CRAY* floating-point data conversion in effect

'FDX'	If the file is connected with little endian integer and VAX* processor F_floating, D_floating, and IEEE binary128 data conversion in effect
'FGX'	If the file is connected with little endian integer and VAX processor F_floating, G_floating, and IEEE binary128 data conversion in effect
'IBM'	If the file is connected with big endian integer and IBM* System \370 floating-point data conversion in effect
'VAXD'	If the file is connected with little endian integer and VAX processor F_floating, D_floating, and H_floating in effect
'VAXG'	If the file is connected with little endian integer and VAX processor F_floating, G_floating, and H_floating in effect
'NATIVE'	If the file is connected with no data conversion in effect
'UNKNOWN'	If the file or unit is not connected for unformatted data transfer

INQUIRE: DECIMAL Specifier

The DECIMAL specifier asks which decimal editing mode is in effect for a file connection. It takes the following form:

DECIMAL = *dmode*

dmode Is a scalar default character variable that is assigned one of the following values:

'COMMA'	If a decimal comma is used during decimal editing mode.
'POINT'	If a decimal point is used during decimal editing mode.
'UNDEFINED'	If there is no connection or if the connection is not for formatted I/O.

INQUIRE: DELIM Specifier

The DELIM specifier asks how character constants are delimited in list-directed and namelist output. It takes the following form:

DELIM = *del*

del

Is a scalar default character variable that is assigned one of the following values:

'APOSTROPHE'	If apostrophes are used to delimit character constants in list-directed and namelist output
'QUOTE'	If quotation marks are used to delimit character constants in list-directed and namelist output
'NONE'	If no delimiters are used
'UNDEFINED'	If the file is not connected, or is not connected for formatted data transfer

INQUIRE: DIRECT Specifier

The DIRECT specifier asks whether a file is connected for direct access. It takes the following form:

DIRECT = *dir*

dir

Is a scalar default character variable that is assigned one of the following values:

'YES'	If the file is connected for direct access
'NO'	If the file is not connected for direct access
'UNKNOWN'	If the file is not connected

INQUIRE: ENCODING Specifier

The ENCODING specifier asks what type of encoding is in effect for a file. It takes the following form:

ENCODING = *enc*

enc

Is a scalar default character expression that is assigned one of the following values:

'UTF-8'	If the file is connected with UTF-8 encoding in effect.
'UNDEFINED'	If the file is connected for unformatted I/O.
'UNKNOWN'	If the processor is unable to determine the encoding form of the file.

INQUIRE: EXIST Specifier

The EXIST specifier asks whether a file exists and can be opened. It takes the following form:

EXIST = *ex*

ex Is a scalar default logical variable that is assigned one of the following values:

.TRUE.	If the specified file exists and can be opened, or if the specified unit exists
.FALSE.	If the specified file or unit does not exist or if the file exists but cannot be opened

The unit exists if it is a number in the range allowed by the processor.

INQUIRE: FORM Specifier

The FORM specifier asks whether a file is connected for formatted, unformatted, or binary (W*S) data transfer. It takes the following form:

FORM = *fm*

fm Is a scalar default character variable that is assigned one of the following values:

'FORMATTED'	If the file is connected for formatted data transfer
'UNFORMATTED'	If the file is connected for unformatted data transfer
'BINARY'	If the file is connected for binary data transfer
'UNDEFINED'	If the file is not connected

INQUIRE: FORMATTED Specifier

The FORMATTED specifier asks whether a file is connected for formatted data transfer. It takes the following form:

FORMATTED = *fmt*

fmt Is a scalar default character variable that is assigned one of the following values:

'YES'	If the file is connected for formatted data transfer
'NO'	If the file is not connected for formatted data transfer
'UNKNOWN'	If the processor cannot determine whether the file is connected for formatted data transfer

INQUIRE: IOFOCUS Specifier (W*S)

The IOFOCUS specifier asks if the indicated unit is the active window in a QuickWin application. It takes the following form:

IOFOCUS = *iof*

iof Is a scalar default logical variable that is assigned one of the following values:

.TRUE.	If the specified unit is the active window in a QuickWin application
.FALSE.	If the specified unit is not the active window in a QuickWin application

If unit '*' is specified, the default is .FALSE.; otherwise, the default is .TRUE..

A value of .TRUE. causes a call to FOCUSQQ immediately before any READ, WRITE, or PRINT statement to that window.

If you use this specifier with a non-Windows application, an error occurs.

INQUIRE: MODE Specifier

MODE is a nonstandard synonym for ACTION.

INQUIRE: NAME Specifier

The NAME specifier returns the name of a file. It takes the following form:

NAME = *nme*

nme Is a scalar default character variable that is assigned the name of the file to which the unit is connected. If the file does not have a name, *nme* is undefined.

The value assigned to *nme* is not necessarily the same as the value given in the FILE specifier. However, the value that is assigned is always valid for use with the FILE specifier in an OPEN statement, unless the value has been truncated in a way that makes it unacceptable. (Values are truncated if the declaration of *nme* is too small to contain the entire value.)

NOTE
The FILE and NAME specifiers are synonyms when used with the OPEN statement, but not when used with the INQUIRE statement.

See Also

The appropriate manual in your operating system documentation set for details on the maximum size of file pathnames

INQUIRE: NAMED Specifier

The NAMED specifier asks whether a file is named. It takes the following form:

NAMED = *nmd*

nmd

Is a scalar default logical variable that is assigned one of the following values:

.TRUE.	If the file has a name
.FALSE.	If the file does not have a name

INQUIRE: NEXTREC Specifier

The NEXTREC specifier asks where the next record can be read or written in a file connected for direct access. It takes the following form:

NEXTREC = *nr*

nr

Is a scalar integer variable that is assigned a value as follows:

- If the file is connected for direct access and a record (r) was previously read or written, the value assigned is r + 1.
- If no record has been read or written, the value assigned is 1.
- If there are pending asynchronous data transfer operations for the specified file, the value assigned is computed as if all pending data transfers have already completed.
- If the file is not connected for direct access, or if the file position cannot be determined because of an error condition, the value assigned is zero.
- If the file is connected for direct access and a REWIND has been performed on the file, the value assigned is 1.

INQUIRE: NUMBER Specifier

The NUMBER specifier asks the number of the unit connected to a file. It takes the following form:

NUMBER = *num*

num

Is a scalar integer variable.

The *num* is assigned the number of the unit currently connected to the specified file. If there is no unit connected to the file, the value assigned is -1.

INQUIRE: OPENED Specifier

The OPENED specifier asks whether a file is connected. It takes the following form:

OPENED = *od*

od

Is a scalar default logical variable that is assigned one of the following values:

.TRUE.	If the specified file or unit is connected
.FALSE.	If the specified file or unit is not connected

INQUIRE: ORGANIZATION Specifier

The ORGANIZATION specifier asks how the file is organized. It takes the following form:

ORGANIZATION = *org*

org Is a scalar default character variable that is assigned one of the following values:

'SEQUENTIAL'	If the file is a sequential file
'RELATIVE'	If the file is a relative file
'UNKNOWN'	If the processor cannot determine the file's organization

INQUIRE: PAD Specifier

The PAD specifier asks whether blank padding was specified for the file. It takes the following form:

PAD = *pd*

pd Is a scalar default character variable that is assigned one of the following values:

'NO'	If the file or unit was connected with PAD='NO'
'YES'	If the file or unit is not connected, or it was connected with PAD='YES'

INQUIRE: PENDING Specifier

The PENDING specifier asks whether previously pending asynchronous data transfers are complete. A data transfer is previously pending if it is not complete at the beginning of execution of the INQUIRE statement. It takes the following form:

PENDING = *pnd*

pnd Is a scalar default logical variable that is assigned the value .TRUE. or .FALSE..

The value is assigned as follows:

- If an ID specifier appears in the INQUIRE statement, the following occurs:
  - If the data transfer specified by ID is complete, then variable *pnd* is set to .FALSE. and INQUIRE performs the WAIT operation for the specified data transfer.
  - If the data transfer specified by ID is not complete, then variable *pnd* is set to .TRUE. and no WAIT operation is performed. The previously pending data transfer remains pending after the execution of the INQUIRE statement.
- If an ID specifier does not appear in the INQUIRE statement, the following occurs:
  - If all previously pending data transfers for the specified unit are complete, then variable *pnd* is set to .FALSE. and the INQUIRE statement performs WAIT operations for all previously pending data transfers for the specified unit.
  - If there are data transfers for the specified unit that are not complete, then variable *pnd* is set to .TRUE. and no WAIT operations are performed. The previously pending data transfers remain pending after the execution of the INQUIRE statement.

See Also

ID Specifier

Example in INQUIRE Statement

INQUIRE: POS Specifier

The POS specifier identifies the file position in file storage units in a stream file. It takes the following form:

POS = *p*

p	Is a scalar integer variable that is assigned the number of the file storage unit immediately following the current position of a file connected for stream access (ACCESS='STREAM').

If the file is positioned at its terminal position, *p* is assigned a value one greater than the number of the highest-numbered file storage unit in the file.

If the file is not connected for stream access or if the position of the file is indeterminate because of previous error conditions, *p* is assigned the value one.

If there are pending asynchronous data operations for the specified file, the value assigned to the POS= specifier is computed as if all pending data transfers have already completed.

INQUIRE: POSITION Specifier

The POSITION specifier asks the position of the file. It takes the following form:

POSITION = *pos*

pos — Is a scalar default character variable that is assigned one of the following values:

'REWIND'	If the file is connected with its position at its initial point
'APPEND'	If the file is connected with its position at its terminal point (or before its end-of-file record, if any)
'ASIS'	If the file is connected without changing its position
'UNDEFINED'	If the file is not connected, or is connected for direct access data transfer and a REWIND statement has not been performed on the unit

INQUIRE: READ Specifier

The READ specifier asks whether a file can be read. It takes the following form:

READ = *rd*

rd — Is a scalar default character variable that is assigned one of the following values:

'YES'	If the file can be read
'NO'	If the file cannot be read
'UNKNOWN'	If the processor cannot determine whether the file can be read

INQUIRE: READWRITE Specifier

The READWRITE specifier asks whether a file can be both read and written to. It takes the following form:

READWRITE = *rdwr*

rdwr

Is a scalar default character variable that is assigned one of the following values:

'YES'	If the file can be both read and written to
'NO'	If the file cannot be both read and written to
'UNKNOWN'	If the processor cannot determine whether the file can be both read and written to

INQUIRE: RECL Specifier

The RECL specifier asks the maximum record length for a file. It takes the following form:

RECL = *rcl*

rcl

Is a scalar integer variable that is assigned a value as follows:

- If the file or unit is connected, the value assigned is the maximum record length allowed.
- If the file does not exist, or it is not connected, the value assigned is zero.

  Fortran 2018 standardizes the value assigned to be -1 when the file does not exist, or it is not connected. To get the Fortran 2018 behavior, specify compiler option `assume -noold_inquire_recl`.
- If the file is connected for stream access, the value is undefined. Fortran 2018 standardizes this value to be -2. To get the Fortran 2018 behavior, specify compiler option `assume -noold_inquire_recl`.

The assigned value is expressed in 4-byte units if the file is currently (or was previously) connected for unformatted data transfer and the `assume byterecl` compiler option is not in effect; otherwise, the value is expressed in bytes.

INQUIRE: RECORDTYPE Specifier

The RECORDTYPE specifier asks which type of records are in a file. It takes the following form:

RECORDTYPE = *rtype*

rtype Is a scalar default character variable that is assigned one of the following values:

'FIXED'	If the file is connected for fixed-length records
'VARIABLE'	If the file is connected for variable-length records
'SEGMENTED'	If the file is connected for unformatted sequential data transfer using segmented records
'STREAM'	If the file's records are not terminated
'STREAM_CR'	If the file's records are terminated with a carriage return
'STREAM_LF'	If the file's records are terminated with a line feed
'STREAM_CRLF'	If the file's records are terminated with a carriage return/line feed pair
'UNKNOWN'	If the file is not connected

INQUIRE: ROUND Specifier

The ROUND specifier asks which rounding mode is in effect for a file connection. It takes the following form:

ROUND = *rmode*

rmode Is a scalar default character expression that is assigned one of the following values:

'UP'	If the I/O rounding is set to the smallest representable value that is greater than or equal to the original value.
'DOWN'	If the I/O rounding is set to the largest representable value that is less than or equal to the original value.
'ZERO'	If the I/O rounding is set to the value closest to the original value, but no greater in magnitude than the original value.
'NEAREST'	Conforms to the ISO/IEC/IEEE 60559:2011 standard specification for roundTiesToEven.

'COMPATIBLE'	If the I/O rounding is set to the closer of the two nearest representable values, or the value farther from zero if halfway between them.
'PROCESSOR_DEFINED'	If the I/O rounding mode behaves differently than the UP, DOWN, ZERO, NEAREST, and COMPATIBLE modes.
'UNDEFINED'	If there is no connection or if the connection is not for formatted I/O.

The rounding modes conform to the corresponding rounding modes specified in the ISO/IEC/IEEE 60559:2011 standard.

INQUIRE: SEQUENTIAL Specifier

The SEQUENTIAL specifier asks whether a file is connected for sequential access. It takes the following form:

SEQUENTIAL = *seq*

seq Is a scalar default character variable that is assigned one of the following values:

'YES'	If the file is connected for sequential access
'NO'	If the file is not connected for sequential access
'UNKNOWN'	If the processor cannot determine whether the file is connected for sequential access

INQUIRE: SHARE Specifier

The SHARE specifier asks the current share status of a file or unit. It takes the following form:

SHARE = *shr*

shr Is a scalar default character variable.

On Windows* systems, this variable is assigned one of the following values:

'DENYRW'	If the file is connected for deny-read/write mode
'DENYWR'	If the file is connected for deny-write mode
'DENYRD'	If the file is connected for deny-read mode
'DENYNONE'	If the file is connected for deny-none mode

'UNKNOWN'	If the file or unit is not connected
On Linux* and macOS* systems, this variable is assigned one of the following values:	
'DENYRW'	If the file is connected for exclusive access
'DENYNONE'	If the file is connected for shared access
'NODENY'	If the file is connected with default locking
'UNKNOWN'	If the file or unit is not connected

INQUIRE: SIGN Specifier

The SIGN specifier asks what treatment for plus signs is in effect during a connection. It takes the following form:

SIGN = *sn*

sn Is a scalar default character expression that is assigned one of the following values:

'PLUS'	If the file is connected with addition of plus signs in effect.
'SUPPRESS'	If the file is connected with suppression of plus signs in effect.
'PROCESSOR_DEFINED'	If the file is connected with plus signs added at the discretion of the processor.
'UNDEFINED'	If there is no connection, or if the connection is not for formatted input/output.

INQUIRE: SIZE Specifier

The SIZE specifier asks the size of a file in file storage units. It takes the following form:

SIZE = *sz*

sz Is a scalar integer variable.

The *sz* variable is assigned the size of the file in file storage units. If the file size cannot be determined, the variable is assigned the value -1.

For a file that is connected for stream access, the file size is the number of the highest-numbered file storage unit in the file.

For a file that is connected for sequential or direct access, the file size may be different from the number of storage units implied by the data in the records; the exact relationship is processor-dependent.

If there are pending asynchronous data transfer operations for the specified file, the value assigned to the SIZE= specifier is computed as if the pending data transfers have already completed.

INQUIRE: UNFORMATTED Specifier

The UNFORMATTED specifier asks whether a file is connected for unformatted data transfer. It takes the following form:

UNFORMATTED = *unf*

unf Is a scalar default character variable that is assigned one of the following values:

'YES'	If the file is connected for unformatted data transfer
'NO'	If the file is not connected for unformatted data transfer
'UNKNOWN'	If the processor cannot determine whether the file is connected for unformatted data transfer

INQUIRE: WRITE Specifier

The WRITE specifier asks whether a file can be written to. It takes the following form:

WRITE = *wr*

wr Is a scalar default character variable that is assigned one of the following values:

'YES'	If the file can be written to
'NO'	If the file cannot be written to
'UNKNOWN'	If the processor cannot determine whether the file can be written to

OPEN Statement Specifiers

The OPEN statement connects an external file to a unit, creates a new file and connects it to a unit, creates a preconnected file, or changes certain properties of a connection. For more information, see OPEN.

The following table summarizes the OPEN statement specifiers and contains links to their descriptions:

OPEN Statement Specifiers and Values

Specifier	Values	Function	Default
ACCESS	'DIRECT' 'SEQUENTIAL' 'STREAM' 'APPEND'	Access mode	'SEQUENTIAL'
ACTION	'READ'	File access	'READWRITE'

Specifier	Values	Function	Default
(or MODE)	'WRITE' 'READWRITE'		
ASSOCIATEVARIABLE	var	Next direct access record	No default
ASYNCHRONOUS	'YES' 'NO'	Asynchronous I/O	'NO'
BLANK	'NULL' 'ZERO'	Interpretation of blanks	'NULL'
BLOCKSIZE	n_expr	Physical I/O transfer size	131,072 bytes
BUFFERCOUNT	n_expr	Number of I/O buffers	One
BUFFERED	'YES' 'NO'	Buffering for WRITE operations; buffering for READ operations on variable length, unformatted, input records	'NO' [1]
CARRIAGECONTROL	'FORTRAN' 'LIST' 'NONE'	Print control	Formatted: 'LIST'[2] Unformatted: 'NONE'
CONVERT	'LITTLE_ENDIAN' 'BIG_ENDIAN' 'CRAY' 'FDX' 'FGX' 'IBM' 'VAXD' 'VAXG' 'NATIVE'	Numeric format specification	'NATIVE'
DECIMAL	'COMMA' 'POINT'	Decimal edit mode	'POINT'
DEFAULTFILE	c_expr	Default file pathname	Current working directory
DELIM	'APOSTROPHE' 'QUOTE' 'NONE'	Delimiter for character constants	'NONE'
DISPOSE(or DISP)	'KEEP' or 'SAVE' 'DELETE' 'PRINT'	File disposition at close	'KEEP'

Specifier	Values	Function	Default
	'PRINT/DELETE' 'SUBMIT' 'SUBMIT/DELETE'		
ENCODING	'UTF-8' 'DEFAULT'	Encoding form for a file	'DEFAULT'
ERR	label	Error transfer control	No default
FILE(or NAME)	c_expr	File pathname (file name)	fort.n [3]
FORM	'FORMATTED' 'UNFORMATTED' 'BINARY'	Format type	Depends on ACCESS setting
IOFOCUS	.TRUE. .FALSE.	Active window in QuickWin application	.TRUE.[4]
IOSTAT	var	I/O status	No default
MAXREC	n_expr	Direct access record limit	No limit
NEWUNIT	var	Returns automatically chosen, unused, unit number	No default
NOSHARED	No value	File sharing disallowed	L*X, M*X: SHARED W*32: Not shared
ORGANIZATION	'SEQUENTIAL' 'RELATIVE'	File organization	'SEQUENTIAL'
PAD	'YES' 'NO'	Record padding	'YES'
POSITION	'ASIS' 'REWIND' 'APPEND'	File positioning	'ASIS'
READONLY	No value	Write protection	No default
RECL (or RECORDSIZE)	n_expr	Record length	Depends on RECORDTYPE,ORGANIZATION, and FORM settings [5]
RECORDTYPE	'FIXED' 'VARIABLE' 'SEGMENTED' 'STREAM' 'STREAM_CR'	Record type	Depends on ORGANIZATION, CARRIAGECONTROL, ACCESS, and FORM settings

Specifier	Values	Function	Default
	'STREAM_LF'		
ROUND	'UP' 'DOWN' 'ZERO' 'NEAREST' 'COMPATIBLE' 'PROCESSOR_DEFINED'	Rounding mode	'PROCESSOR_DEFINED' - for `ifort`, this corresponds to 'NEAREST' as in the ISO/IEC/IEEE 60559:2011 standard specification for roundTiesToEven
SHARE	'DENYRW' 'DENYWR'[5] 'DENYRD'[6] 'DENYNONE'	File locking	'DENYWR' [7]
SHARED	No value	File sharing allowed	L*X, M*X: SHARED W*S: Not shared
SIGN	'PLUS' 'SUPPRESS' 'PROCESSOR_DEFINED'	Plus sign mode	'PROCESSOR_DEFINED'
STATUS(or TYPE)	'OLD' 'NEW' 'SCRATCH' 'REPLACE' 'UNKNOWN'	File status at open	'UNKNOWN' [8]
TITLE	c_expr	Title for child window in QuickWin application	No default
UNIT	n_expr	Logical unit number	No default; an io-unit must be specified
USEROPEN	func	User program option	No default

[1] The default is also 'NO' when reading variable length, unformatted records whose length exceeds that of the block size specified for the file.

[2] If you use the compiler option specifying OpenVMS defaults, and the unit is connected to a terminal, the default is 'FORTRAN'.

[3] n is the unit number.

[4] If unit '*' is specified, the default is .FALSE.; otherwise, the default is .TRUE..

[5] On Linux* and macOS* systems, the default depends only on the FORM setting.

[6] W*S

[7] The default differs under certain conditions (see SHARE Specifier).

[8] The default differs under certain conditions (see STATUS Specifier).

Specifier	Values	Function	Default

Key to Values

```
c_expr: A scalar default character expression
func:   An external function
label:  A statement label
n_expr: A scalar numeric expression
var:    A scalar integer variable
```

See Also

INQUIRE Statement for details on using the INQUIRE statement to get file attributes of existing files

OPEN: ACCESS Specifier

The ACCESS specifier indicates the access method for the connection of the file. It takes the following form:

ACCESS = *acc*

acc Is a scalar default character expression that evaluates to one of the following values:

'DIRECT'	Indicates direct access.
'SEQUENTIAL'	Indicates sequential access.
'STREAM'	Indicates stream access, where the file storage units of the file are accessible sequentially or by position.
'APPEND'	Indicates sequential access, but the file is positioned at the end-of-file record.

The default is 'SEQUENTIAL'.

There are limitations on record access by file organization and record type.

OPEN: ACTION Specifier

The ACTION specifier indicates the allowed I/O operations for the file connection. It takes the following form:

ACTION = *act*

act Is a scalar default character expression that evaluates to one of the following values:

'READ'	Indicates that only READ statements can refer to this connection.
'WRITE'	Indicates that only WRITE, DELETE, and ENDFILE statements can refer to this connection.

'READWRITE'	Indicates that READ, WRITE, DELETE, and ENDFILE statements can refer to this connection.

The default is 'READWRITE'.

However, if compiler option fpscomp general is specified on the command line and *action* is omitted, the system first attempts to open the file with 'READWRITE'. If this fails, the system tries to open the file again, first using 'READ', then using 'WRITE'.

Note that in this case, omitting *action* is not the same as specifying ACTION='READWRITE'. If you specify ACTION='READWRITE' and the file cannot be opened for both read and write access, the attempt to open the file fails. You can use the INQUIRE statement to determine the actual access mode selected.

See Also

fpscomp compiler option

OPEN: ASSOCIATEVARIABLE Specifier

The ASSOCIATEVARIABLE specifier indicates a variable that is updated after each direct access I/O operation, to reflect the record number of the next sequential record in the file. It takes the following form:

ASSOCIATEVARIABLE = *asv*

asv	Is a scalar integer variable. It cannot be a dummy argument to the routine in which the OPEN statement appears.

Direct access READs, direct access WRITEs, and the FIND, DELETE, and REWRITE statements can affect the value of *asv*.

This specifier is valid only for direct access; it is ignored for other access modes.

OPEN: ASYNCHRONOUS Specifier

The ASYNCHRONOUS specifier indicates whether asynchronous I/O is allowed for a unit. It takes the following form:

ASYNCHRONOUS = *asyn*

asyn	Is a scalar expression of type default character that evaluates to one of the following values:

'YES'	Indicates that asynchronous I/O is allowed for a unit.
'NO'	Indicates that asynchronous I/O is not allowed for a unit.

The default is 'NO'.

OPEN: BLANK Specifier

The BLANK specifier indicates how blanks are interpreted in a file. It takes the following form:

BLANK = *blnk*

blnk	Is a scalar default character expression that evaluates to one of the following values:

'NULL'	Indicates all blanks are ignored, except for an all-blank field (which has a value of zero).
'ZERO'	Indicates all blanks (other than leading blanks) are treated as zeros.

The default is 'NULL' (for explicitly OPENed files, preconnected files, and internal files). If you specify compiler option f66 (or OPTIONS/NOF77), the default is 'ZERO'.

If the BN or BZ edit descriptors are specified for a formatted input statement, they supersede the default interpretation of blanks.

See Also

Blank Editing for details on the BN and BZ edit descriptors
f66

OPEN: BLOCKSIZE Specifier

The BLOCKSIZE specifier indicates the physical I/O transfer size in bytes for the file. It takes the following form:

BLOCKSIZE = *bks*

bks	Is a scalar numeric expression. If necessary, the value is converted to integer data type before use.

If you specify a nonzero number for *bks*, it is rounded up to a multiple of 512 byte blocks. The maximum valid value of BLOCKSIZE is 2147467264.

If you do not specify BLOCKSIZE or you specify zero for *bks*, the default value of 128 KB (131,072 bytes) is assumed. However, if you compile with the `assume buffered_stdout` option, the default blocksize for `stdout` is 8 KB.

The default BLOCKSIZE value can be changed by using the FORT_BLOCKSIZE environment variable or by specifying the BLOCKSIZE parameter on the unit's OPEN. The BLOCKSIZE value can be changed for `stdout` by re-opening the unit corresponding to stdout with an explicit BLOCKSIZE parameter; for example:

```
OPEN(6,ACCESS='SEQUENTIAL',FORM='FORMATTED',BUFFERED='YES',BLOCKSIZE=1048576
```

OPEN: BUFFERCOUNT Specifier

The BUFFERCOUNT specifier indicates the number of buffers to be associated with the unit for multibuffered I/O. It takes the following form:

BUFFERCOUNT = *bc*

bc	Is a scalar numeric expression in the range 1 through 127. If necessary, the value is converted to integer data type before use.

The BLOCKSIZE specifier determines the size of each buffer. For example, if BUFFERCOUNT=3 and BLOCKSIZE=2048, the total number of bytes allocated for buffers is 3*2048, or 6144 bytes.

If you do not specify BUFFERCOUNT or you specify zero for *bc*, the default is 1.

See Also

BLOCKSIZE specifier

OPEN: BUFFERED Specifier

The BUFFERED specifier indicates run-time library behavior for READ and WRITE operations. Buffering of input records only applies to variable length, unformatted records. This specifier takes the following form:

BUFFERED = *bf*

bf Is a scalar default character expression that evaluates to one of the following values:

'NO'	For WRITE operations: Requests that the run-time library send output data to the file system after each operation. For READ operations on variable length, unformatted files: Requests that the run-time library transfer input data directly from disk to user variables for each operation.
'YES'	Requests that the run-time library accumulate data in its internal buffer, possibly across several READ or WRITE operations, before the data is transferred to, or from, the file system. Buffering may improve run-time performance for output-intensive applications.

The default is 'NO' for buffering output. The default is also 'NO' when reading variable length, unformatted records whose length exceeds that of the block size specified for the file.

If BUFFERED='YES' is specified, the request may or may not be honored, depending on the device and other file or connection characteristics.

For direct access, you should specify BUFFERED='YES', although using direct-access I/O to a network file system may be much slower.

If both BLOCKSIZE and BUFFERCOUNT for OPEN have been specified with positive values, their product determines the size in bytes of the buffer for that I/O unit. Otherwise, the default size of the internal buffer is 8 KB (8192 bytes).

NOTE
On Windows systems, the default size of the internal buffer is 1024 bytes if compiler option fpscomp general is used.

The internal buffer will grow to hold the largest single record but will never shrink.

See Also

Rules for Unformatted Sequential READ Statements

OPEN: CARRIAGECONTROL Specifier

The CARRIAGECONTROL specifier indicates the type of carriage control used when a file is displayed at a terminal. It takes the following form:

CARRIAGECONTROL = *cc*

cc Is a scalar default character expression that evaluates to one of the following values:

'FORTRAN'	Indicates normal Fortran interpretation of the first character.
'LIST'	Indicates one line feed between records.
'NONE'	Indicates no carriage control processing.

The default for binary (W*S) and unformatted files is 'NONE'. The default for formatted files is 'LIST'. However, if you specify compiler option vms or fpscomp general, and the unit is connected to a terminal, the default is 'FORTRAN'.

On output, if a file was opened with CARRIAGECONTROL='FORTRAN' in effect or the file was processed by the `fortpr` format utility, the first character of a record transmitted to a line printer or terminal is typically a character that is not printed, but is used to control vertical spacing.

See Also

Printing of Formatted Records for details on valid control characters for printing
vms compiler option
fpscomp compiler option

OPEN: CONVERT Specifier

The CONVERT specifier indicates a nonnative numeric format for unformatted data. It takes the following form:

CONVERT = *fm*

fm Is a scalar default character expression that evaluates to one of the following values:

'LITTLE_ENDIAN'[1]	Little endian integer data [2] and IEEE* floating-point data. [3]
'BIG_ENDIAN'[1]	Big endian integer data [2] and IEEE floating-point data. [3]
'CRAY'	Big endian integer data [2] and CRAY* floating-point data of size REAL(8) or COMPLEX(8).
'FDX'	Little endian integer data [2] and VAX* processor floating-point data of format F_floating for REAL(4) or COMPLEX(4), D_floating for size REAL(8) or COMPLEX(8), and IEEE binary128 for REAL(16) or COMPLEX(16).
'FGX'	Little endian integer data [2] and VAX processor floating-point data of format F_floating for REAL(4) or COMPLEX(4),

	G_floating for size REAL(8) or COMPLEX(8), and IEEE binary128 for REAL(16) or COMPLEX(16).
'IBM'	Big endian integer data [2] and IBM* System\370 floating-point data of size REAL(4) or COMPLEX(4) (IBM short 4), and size REAL(8) or COMPLEX(8) (IBM long 8).
'VAXD'	Little endian integer data [2] and VAX processor floating-point data of format F_floating for size REAL(4) or COMPLEX(4), D_floating for size REAL(8) or COMPLEX(8), and H_floating for REAL(16) or COMPLEX(16).
'VAXG'	Little endian integer data [2] and VAX processor floating-point data of format F_floating for size REAL(4) or COMPLEX(4), G_floating for size REAL(8) or COMPLEX(8), and H_floating for REAL(16) or COMPLEX(16).
'NATIVE'	No data conversion. This is the default.

[1] INTEGER(1) data is the same for little endian and big endian.

[2] Of the appropriate size: INTEGER(1), INTEGER(2), INTEGER(4), or INTEGER(8)

[3] Of the appropriate size and type: REAL(4), REAL(8), REAL(16), COMPLEX(4), COMPLEX(8), or COMPLEX(16)

You can use CONVERT to specify multiple formats in a single program, usually one format for each specified unit number.

When reading a nonnative format, the nonnative format on disk is converted to native format in memory. If a converted nonnative value is outside the range of the native data type, a run-time message appears.

There are other ways to specify numeric format for unformatted files: you can specify an environment variable, compiler option convert, or OPTIONS/CONVERT. The following shows the order of precedence:

Method Used	Precedence
An environment variable	Highest
OPEN (CONVERT=)	.
OPTIONS/CONVERT	.
The convert compiler option	Lowest

Compiler option convert and OPTIONS/CONVERT affect all unit numbers used by the program, while environment variables and OPEN (CONVERT=) affect specific unit numbers.

The following example shows how to code the OPEN statement to read unformatted CRAY* numeric data from unit 15, which might be processed and possibly written in native little endian format to unit 20:

```
   OPEN (CONVERT='CRAY', FILE='graph3.dat', FORM='UNFORMATTED',
1      UNIT=15)
   ...
   OPEN (FILE='graph3_native.dat', FORM='UNFORMATTED', UNIT=20)
```

See Also

Data Types, Constants, and Variables for details on supported ranges for data types

convert compiler option

OPEN: DECIMAL Specifier

The DECIMAL specifier controls the representation of the decimal symbol for a connection. It takes the following form:

DECIMAL = *dmode*

dmode Is a scalar default character expression that evaluates to one of the following values:

'COMMA'	Indicates that a decimal comma should be used for decimal editing mode.
'POINT'	Indicates that a decimal point should be used for decimal editing mode.

The default decimal editing mode is 'POINT'.

You can only use this specifier for a formatted I/O connection.

When the mode is DECIMAL='POINT', the decimal point in a numeric input or output value is a period, values are separated by commas in list-directed and NAMELIST I/O, and the separator between the real and imaginary parts of a complex value is a comma.

When the mode is DECIMAL='COMMA', the decimal point in a numeric input or output value is a comma, values are separated by semicolons in list-directed and NAMELIST I/O, and the separator between the real and imaginary parts of a complex value is a semicolon.

The decimal editing mode can be temporarily changed within a READ or WRITE statement by the DECIMAL= specifier or by the corresponding DC and DP edit descriptors.

OPEN: DEFAULTFILE Specifier

The DEFAULTFILE specifier indicates a default file pathname string. It takes the following form:

DEFAULTFILE = *def*

def Is a character expression indicating a default file pathname string.

The default file pathname string is used primarily when accepting file pathnames interactively. File pathnames known to a user program normally appear in the FILE specifier.

DEFAULTFILE supplies a value to the Fortran I/O system that is prefixed to the name that appears in FILE.

If *def* does not end in a slash (/), a slash is added.

If DEFAULTFILE is omitted, the Fortran I/O system uses the current working directory.

OPEN: DELIM Specifier

The DELIM specifier indicates what characters (if any) are used to delimit character constants in list-directed and namelist output. It takes the following form:

DELIM = *del*

del Is a scalar default character expression that evaluates to one of the following values:

'APOSTROPHE'	Indicates apostrophes delimit character constants. All internal apostrophes are doubled.
'QUOTE'	Indicates quotation marks delimit character constants. All internal quotation marks are doubled.
'NONE'	Indicates character constants have no delimiters. No internal apostrophes or quotation marks are doubled.

The default is 'NONE'.

The DELIM specifier is only allowed for files connected for formatted data transfer; it is ignored during input.

OPEN: DISPOSE Specifier

The DISPOSE (or DISP) specifier indicates the status of the file after the unit is closed. It takes one of the following forms:

DISPOSE = *dis*

DISP = *dis*

dis Is a scalar default character expression that evaluates to one of the following values:

'KEEP' or 'SAVE'	Retains the file after the unit closes.
'DELETE'	Deletes the file after the unit closes.
'PRINT' [1]	Submits the file to the line printer spooler and retains it.
'PRINT/DELETE' [1]	Submits the file to the line printer spooler and then deletes it.
'SUBMIT'	Forks a process to execute the file.
'SUBMIT/DELETE'	Forks a process to execute the file, and then deletes the file after the fork is completed.

[1] Use only on sequential files.

The default is 'DELETE' for scratch files. For all other files, the default is 'KEEP'.

OPEN: ENCODING Specifier

The ENCODING specifier indicates the encoding form for a file. It takes the following form:

ENCODING = *enc*

enc — Is a scalar default character expression that evaluates to one of the following values:

'UTF-8'	Indicates that the encoding form of the file is UTF-8 (a unicode file). All characters therein are of ISO 10646 character type, as specified by ISO/IEC 10646-1:2000. This value must not be specified if the processor does not support the ISO 10646 character type.
'DEFAULT'	Indicates that the encoding form of the file is determined by the processor.

The default is 'DEFAULT'.

You can only use this specifier for a formatted I/O connection.

OPEN: FILE Specifier

The FILE specifier indicates the name of the file to be connected to the unit. It takes the following form:

FILE = *name*

name — Is a character or numeric expression.

The *name* can be any pathname allowed by the operating system.

Any trailing blanks in the name are ignored.

If the following conditions occur:

- FILE is omitted
- The unit is not connected to a file
- STATUS='SCRATCH' is not specified
- The corresponding FORT*n* environment variable is not set for the unit number

then Intel® Fortran generates a file name in the form fort.*n*, where *n* is the logical unit number. On Windows systems, if compiler option fpscomp general is specified, omitting FILE implies STATUS='SCRATCH'.

If the file name is stored in a numeric scalar or array, the name must consist of ASCII characters terminated by an ASCII null character (zero byte). However, if it is stored in a character scalar or array, it must not contain a zero byte.

On Windows systems, if the filename is 'USER' or 'CON', input and output are directed to the console. .

In a Windows* QuickWin application, you can specify FILE='USER' to open a child window. All subsequent I/O statements directed to that unit appear in the child window.

On Windows systems, the *name* can be blank (FILE=' ') if the compatibility compiler option fpscomp filesfromcmd is specified. If the *name* is blank, the following occurs:

1. The program reads a filename from the list of arguments (if any) in the command line that started the program. If the argument is a null or blank string (" "), you are prompted for the corresponding filename. Each successive OPEN statement that specifies a blank name reads the next following command-line argument.
2. If no command-line arguments are specified or there are no more arguments in the list, you are prompted for additional filenames.

   Assume the following command line started the program MYPROG (note that quotation marks (") are used):

   myprog first.fil " " third.txt

   MYPROG contains four OPEN statements with blank filenames, in the following order:

```
OPEN (2, FILE = ' ')
OPEN (4, FILE = ' ')
OPEN (5, FILE = ' ')
OPEN (10, FILE = ' ')
```

   Unit 2 is associated with the file FIRST.FIL. Because a blank argument was specified on the command line for the second filename, the OPEN statement for unit 4 produces the following prompt:

```
Filename missing or blank - Please enter name UNIT 4?
```

   Unit 5 is associated with the file THIRD.TXT. Because no fourth file was specified on the command line, the OPEN statement for unit 10 produces the following prompt:

```
Filename missing or blank - Please enter name UNIT 10?
```

OPEN: FORM Specifier

The FORM specifier indicates whether the file is being connected for formatted, unformatted, or binary (W*S) data transfer. It takes the following form:

FORM = *fm*

fm Is a scalar default character expression that evaluates to one of the following values:

'FORMATTED'	Indicates formatted data transfer
'UNFORMATTED'	Indicates unformatted data transfer
'BINARY'	Indicates binary data transfer

The default is 'FORMATTED' for sequential access files, and 'UNFORMATTED' for direct access files.

The data is stored and retrieved in a file according to the file's access (set by the ACCESS specifier) and the form of the data the file contains.

A *formatted file* is a sequence of formatted records. Formatted records are a series of ASCII characters terminated by an end-of-record mark (a carriage return and line feed sequence). The records in a formatted direct-access file must all be the same length. The records in a formatted sequential file can have varying lengths. All internal files must be formatted.

An *unformatted file* is a sequence of unformatted records. An unformatted record is a sequence of values. Unformatted direct files contain only this data, and each record is padded to a fixed length with undefined bytes. Unformatted sequential files contain the data plus information that indicates the boundaries of each record.

Binary sequential files are sequences of bytes with no internal structure. There are no records. The file contains only the information specified as I/O list items in WRITE statements referring to the file.
